T O

THE RIGHT HONOURABLE

EDWARD LORD HERBERT OF
Cherbury and Castle Island, and one
of his Majesties most Honorable
Counsell of War.

My Lord,

T is not the far-fetcht pedigree of noble Ancestors, nor those Honours your Lordship deservedly possesse, that make mee crave your Patronage to this my Labour; but it is that Heroick mind, enriched with the choice endowments of Nature and Art, and that earnest affection wherewith your Honour entertains all Sciences, Arts, and Artists, with that exquisite Iudgment which sees into the inner man, which embolden and incite me to sue for your Honors assistance, in protecting the fame of him, who by your many favours is made yours. I know the seeming and self-pleasing Wisdom of our times, consists much in cavilling and unjustly carping at all things that see light, and that there are many who earnestly hunt after the publike fame of Learning and Judgment, by this easily trod, and despicable path, which notwithstanding they tread with as much confidence as folly; for that oft-times which they vainly and unjustly brand with opprobrie, outlives their Fate, and flourishes when it is forgot that ever any such as they had being.

I know your Lordships disposition to be far dissenting from these men, and that you rather endeavour to build up the fame of your Learning and Judgement upon a strong laid foundation of your own, than *Herostatus* like, by pulling down any howsoever fair built fabrick of another. I heartily wish that your Honour

A

could

The Epistle Dedicatory.

could propagate this good, and that all Detractors might be turned into Actors, and then I know it would much mitigate their rigour in censuring others, when as they themselves were also exposed unto the same Hazzard,

I think it impertinent to acquaint your Honour with the Nature of the Work, my Pains in translating, or the Benefit that may ensue thereon, for that I know your Honour ignorant of nothing in this kind; neither doubt I of your favourable acceptance of the good will of him, that thinks himself much honoured by being

Yours,

THOMAS JOHNSON.

TO

To the Reader.

Have here for the publike good taken pains to subject my self to common censure, the which I doubt not but to find as various as the faces of the Censurers; but I expect no thanks, nor hunt after other praise, than that I have laboured for my Countries good, if that deserve any. I fear not Calumniation (though sure to hear of it) and therefore I will not Apologize, but inform thee of some things concerning the Author his work, and the reason that induced me to the translation thereof, with some few things besides. For the Author, who was principall Surgeon to two or three Kings of *France*, he was a man well versed in the writings of the Antient and modern Physitians, and Surgeons, as you may evidently find by sundry places alledged in his works. For his experience, or practise (the chief help to attain the highest perfection in this Art) it was wonderfull great, as you may collect by his voyages recorded in the last part of this work; as also by that which *James Guillemau*, Surgeon to the *French King*, a man both learned and judicious in his profession, avers, speaking of his own education and progresse in the Art of Surgery. I so laid (*saith he) the first foundation of this Art in the Hospitall of *Paris*, being as it were, an ample Theater of wounds and diseases of all kindes, that for two whole years, during which time I was there conversant, nothing was consulted of, nothing performed, the Physitians, and Surgeons being present, whereof I was not an Auditor or Astor. There flourished at these times, and yet doth, *Ambrose Parey*, principall Surgeon to the most Christian King, the Author of this great work, most renowned for the most gracious favour of Kings, Princes and Nobles towards him, for his Authority amongst his equals, for his Chirurgicall operations amongst all men. Therefore I earnestly endeavoured to be received into his family, as unto another *Machaon*, or *Podalirius*: once admitted, I so by all dutifullnesse and due respect acquired his favour, that he, unlesse I were present and assisting, did nothing (such is his naturall gentlenesse and curtesie to all such as are studious of the Art) at home or abroad, in the field, in the tents, or lastly in this famous City of *Paris*, about the bodies of Dukes, Noblemen, or Citizens, in whose cure, he by the ardent desire of them all, had still the prime place.

* In his Epistle prefixed before the Latin edition of this Author.

Now for this work, hear what this same man in the same place affirmeth further: I not content with these means, which may seem sufficient, and too much, as desirous to satisfie my long thirst, determined to try whether I could draw, or borrow any thing from strangers, which our men wanted, to the fuller knowledge of Surgery. To this purpose I travailed over *Germany*, and then for four years space I followed the *Spanish Army* in the Low-countries; whereas I did not only carefully cure the wounded Souldier, but also heedfully and curiously observe what way of curing the renowned *Italian, Germane, and Spanish Surgeons* observed, who together with me were imployed in the Hospitall, for the healing of the wounded and sick. I observed them all to take no other course than that which is here delivered by *Parey*. Such as did not understand *French*, got some pieces of this work for large rewards, turned into Latin, or such Languages as they understood, which they kept charily, and made great store of; and they esteemed, and admired, and embraced this work alone, above all other works of Surgery, &c. Our Author also himself, not out of a vain-glorious ostentation, but a mind conscions of the truth of his assertion, affirms thus much of this his work. I have (saith he) so certainly toucht the mark whereat I aimed, that Antiquity may seem to have nothing wherein it may exceed us, besides the glory of invention, nor posterity any thing left, but a certain small hope to add some things, as it is easie to add to former inventions. Thus much concerning our Author, and the excellency of his work.

Now come I to my translation, the which, as desiring more a publike good, than private praise, I have performed plainly and honestly, labouring to fit it to the capacity of the meanest Artist; for these are they to whom I chiefly commend this work, and from whom I expect acceptation. I being by the earnest perswasions of some of this profession, chiefly, and almost wholly perswaded and incited to take this pains, who knowing the disability of understanding this Author in Latin or *French*, in many of the weaker members of the large body of their profession, dispersed over this Kingdome, and the rest of his Majesties Dominions, whose good, and encrease in knowledge may be wisht, that so they may be the better enabled to do good to such as shall implore their aid in their profession.

To the Reader.

There are some (I know) will blame me for Englishing this work, as laying open the mysteries of a worthy Art, to the unworthy view of the vulgar. To such I could answer as *Vide Aul. Gel. l. 20 c. 4.* * *Aristotle* did to *Alexander* : but for the present I will give them these, which I think may satisfie any but the purposely malicious : the first is drawn from the goodnesse of the thing, as intended for those that want such guides to direct them in their Art ; for it is commonly granted, that, *Bonum quo communius eo melius*. Secondly, it hath been the custome of most Writers in all Ages and Countries thus to do : *Hippocrates*, *Galen*, and the other Greeks, writ in their mother tongue the mysteries of their Art : thus did *Celsus*, *Serenus*, and others in Latin : *Mesue*, *Avicen*, *Serapio*, and others, in Arabick ; as also, to go no further, our Author writ this work in his native *French*, and learned men have done the like in this, and all other Arts. And it is a great hinderance to us in these dayes, that we must be forced to learn to understand two or three tongues, before we can learn any science, whereas the Ancients learned and taught theirs in their mother tongue : so that they spent a great deal lesse time about words, and more upon the study of that Art or Science they intended to learn and follow. Thirdly, I must tell you, that, *Ex libris nemo evasit Artifex*, No man becomes a workman by book : so that unlesse they have had some insight in the Art, and be in some sort acquainted both with the tearms of Art ; as also with the knowledge and use of the instruments thereto belonging, if by reading this, or any other book of the like naaure they becomes Surgeons, I must needs liken them (as *Galen* doth another sort of men *) to Pilots by book only : to whose care, I think none of us would commit his safety at Sea, nor any if wise, will commit themselves to these at land, or Sea either, unlesse wholly destitute of other.

Gal. de simp. l. 6.
Τὸ ἴσ' ἐκ βιβλίου
Κυβερνήταις.

The other things whereof I must also give you notice, are these. The figures in the Anatomy are not the same used by my Author (whose were according to those of *Vesalius*) but according to those of *Bauline*, which were used in the work of *Dr. Crook* ; and these indeed are the better and more compleat. Also pag. 528. I thought it better to give the true figure of the Helmet floured *Aconite*, mentioned out of *Pliny*, than to reserve the fained picture of *Matthiolus*, which in our Author was encreased with the further fiction of a Helmet. I have in some few places in the margent, which you shall find marked with a star, put short annotations, for the better illustration of that which is obscure, &c. I have also in the Text to the same purpose, here and there put two or three words, contained in these limits [], which I find here and there turned into a plain Parenthesis, especially toward the latter end of the book, but the matter is not great. Further I must acquaint you that the Apologie and Voiages, being the last part of this work, and not in the Latin, but *French* editions, were translated into *English* out of *French* by *George Baker*, a Surgeon of this City, since that time, as I hear, dead beyond the Seas.

This is all, Courteous Reader, that I have thought necessary to acquaint thee withall concerning this, which I would desire thee to take with the same mind that it is presented to thee, by him that wisheth thee all happinesse.

THOMAS JOHNSON.

THE
A U T H O R S
EPISTLE DEDICATORIE

To Henry the third, the most Christian
King of France and Poland.

As (most Christian King) we see the members of mans body by a friendly consent are alwayes busied, and stand ready to perform those functions for which they are appointed by nature, for the preservation of the whole, of which they are parts; so it is convenient that we, which are, as it were, Citizens of this earthly Common-weal should be diligent in the following of that calling which (by Gods appointment) we have once taken upon us: and content with our present estate, not carried away with rashnesse and envy, desire different and divers things whereof we have no knowledg. He which doth otherwise, perverts & defiles with hated confusion the order and beauty, on which this Univerſ consists. Wherefore when I considered with my self, that I was a member of this great Mundane body, and that no altogether unprofitable; I endeavoured earnestly, that all men should be acquainted with my duty, and that it might be known how much I could profit every man. For God is my witnesse, and all good men known that I have now laboured fifty years with all care and pains in the illustration and amplification of Chirurgery; and that I have so certainly touched the mark whereat I aimed, that Antiquity may seem to have nothing wherein it may exceed us, beside the glory of invention; nor posterity any thing left but a certain small hope to add some things, as it is easie to add to former inventions. In performance whereof, I have been so prodigall of my self, my watchings, faculties and means, that I spared neither time, labour, nor cost, whereby I might satisfie and accomplish my own desires, this my great work, and the desires of the studious. Neither may we doubt but their studies would at length wax cold, if they only furnished with the Theorick and Precepts in Schools and that with much labour, should see no manfull operation, nor manifest way of performing the Art. For which cause I seeking the praise and profit of the French Nation, even with the

The Authors Epistle Dedicatory.

hinderance of my particular estate, have endeavoured to illustrate and increase Chirurgery, hitherto obscure either by the infelicity of the former ages, or the envy of the Professors; and not only with precepts and rules, but being a lover of carved works I beautified it with 300. forms, or graven figures, and apt delineations, in which whosoever shall attentively look shall find five hundred anatomical or organical figures belonging to the Art, (if they be reckoned particularly). To every of these I have given their names and shewed their use, lest they should seem to have been put in vainly for ostentation or delight. But although there be few men of this profession which can bring so much authority to their writings either with reason, or experience as I can; notwithstanding I have not been so arrogant, but intending to publish my work, I first communicated it with men the most excellent in the Art of Physick, who gave me greater encouragement to perfect and publish it, that it might be in common use: professing they wished nothing more, than that it might be turned into Latin, (so by which means it should be known to forain Nations, that there is no kind of Learning which is not delivered with great dexterity of wit in this Kingdom over which you rule. And thus much I dare boldly affirm, that there is scarce any, be he never so stately or supercilious, but that he may here find some thing which may delight him, and by which he may better his knowlrdg. Therefore I doubted not to consecrate this book unto your Majesty both as a Pattern and treasury of my labours, as well in respect of my duty, who am yours by nature and education, as that I might manifest to all, your Highnesse exceeding bounty towards me, in placing me, (having heretofore enjoyed the office of principall Chirurgion under three Kings your Majesties Predecessors) in the same dignity, and that of your own accord. And moreover I did conjecture that it would fall out, as now it doth, that this my work carried through the world by the fame of your Majesties name, should neither fear the face nor view of any, supported by the favour and Majesty of a most invincible Monarch and most excellent and renowned Prince. Neither did King Charles the ninth of happy memory, incited by the relation of the most gracious Queen his Mother, refuse to read it, being he understood it proceeded from him, who having happily passed all his time in private and publick employments, and conversed with all men of all sorts, was judged most worthy to obtain this favour, as to have the front of this work adorned and beautified with the splendor of his prefixed name. I encouraged by this hope, desired that my request should passe as by a certain continuation and succession from a most powerfull, to a most Invincible King; and do wholly consecrate these my labours taken for my Countries good unto your sacred Majesty. God grant that your Majesty may have happy successe of all your enterprises abundantly added to Nestors years.

Patis, 8. Feb. Anno Dom. 1579.

Your most Christian Majesties
faithfull Servant

Ambrose Parey.

The Preface.

Most men derive the Originall of Physick from heaven; for those who hold the best opinion of the Creation of the world, affirm, the Elements being created and separated each from other, man being not as yet made; incontinently by the divine decree, all herbes and plants with infinite variety of flowers, endued with various sents, tastes, colours, and forms, grew and sprung forth of the bowels of the Earth, enriched with so many and great vertues, that it may be thought a great offence to attribute to any other than the deity, the benefit of so great a blessing so necessary for so many uses. Neither could Mans Capacity ever have attained to the knowledg of those things without the guidance of the Divine power. For God the great Creator and fashioner of the World, when first he inspired *Adam* by the breath of his mouth into a living and breathing man, he taught him the nature, the proper operations, faculties and vertues of all things contained in the circuit of this Universe. So that if there be any who would ascribe the glory of this invention to man, he is condemned of ingratitude even by the judgment of *Pliny*. But this knowledg was not buried in oblivion with *Adam*: but by the same gift of God was given to those whom he had chosen and ordained for Physick, to put their helping hands to others that stood in need thereof. Which opinion was not only received in the common manner and by the tacite consent of all Nations, but confirmed by *Moses* in the Scripture. Which thing *Jesus* the son of *Sirach* the wisest amongst the Jews, hath confirmed saying; Honor the Physitian with the honor due unto him, for the most High hath created him because of necessity: and of the Lord cometh the gift of healing. The Lord hath created Medicins of the Earth, and he that is wise will not abhor them. Give place and honour to the Physitian, for God hath created him, let him not go from thee, for thou hast need of him. The *Gracians* who first seem more fully and with greater fame to have professed the Art of Physick, do in a manner consent with this opinion, in acknowledging *Apollo* to have been the inventer thereof, neither did they it without a reasonable cause. For whether by *Apollo* they may understand the Sun who by its gentle and vitall heat doth bring forth, temper and cherish all things; or else some

Genes. 1.
Eccles. 28. 1.

The Preface.

Heros, who incited by an excellent and almost divine understanding first taught and put in practise the Medicinall vertues of Herbs; in which sense *Ovid* brings him in speaking thus :

*Herbes are of mine invention, and through all
The world, they me the first Physitian call.*

The originall of Physick arising from those beginnings shall alwayes be celebrated, as celesstiall, and was increased principally after this manner. After *Apollo*, *Æsculapius* his son instructed by his father reduced this Art being as yet rude and vulgar into a little better and more exquisite form, for which cause he was reputed worthy to be accounted as one of the Gods. At the same time flourished *Chiron* the *Centaure*, who for that he excelled in knowledg of Plants, and taught *Æsculapius* (as many report) their faculties, is thought by *Pliny* and some others to have been the inventor of Physick. *Æsculapius* had two sons, *Podalirius* and *Machaon*, who following their fathers steps and professing Physick, did principally beautifie and practise that part thereof which is called Chirurgery, and for that cause were accounted the Inventers thereof. After those *Asclepiades* left this Art much enlarged as hereditary to his posterity; by whose study and diligence, that part of the Art was invented and annexed, which by a more curious skill searcheth and cureth those diseases which lye hid within the body. *Hippocrates* the *Coan* the son of *Heracidas*, born of the noble race of *Asclepiades*. Prince of the Physitians that were before him, perfected Physick and reduced it into an Art and wrote divers Books thereof in Greek. *Galen* succeeded him six hundred years after, who was a man most famous not only for his knowledg in Physick, but also in all other sciences, who faithfully interpreting every thing that was obscure and difficult in the writings of *Hippocrates*, enlarged the science with many volumes. Thus therefore was the beginning, thus the increase and perfecting the Art of Physick, as much as can be hoped for from mans industry. Although indeed we cannot deny but that Experience hath much profited this Art, as it hath and doth many other. For as men perceived that some things were profitable, some unprofitable for this or that disease, they set it down, and so by diligent observation and marking of singularities, they established universall and certain precepts and so brought it into an Art. For so we find it recorded in ancient Histories, before the invention of Physick, that the *Babylonians* and *Assyrians* had a custom amongst them to lay their sick and diseased persons in the porches and entries of their houses, or to carry them into the streets and market places, that such as passed by and saw them, might give them counsel to take those things to cure their diseases, which they had formerly found profitable in themselves or any other in the like affects, neither might any passe by a sick man in silence.

The Preface.

lence. Also *Strabo* writes that it was a custom in *Greece* that those which were sick should resort to *Æsculapius* his Temple in *Epidaurum*, that there as they slept, by their dreams they might be admonished by the God what means they should use to be cured; and when they were freed from their diseases, they writ the manner of their infirmities and the means by which they were cured in tables and fastened them to the pillars of the Temple, not only for the glory of the God, but also for the profit of such, as should afterwards be affected with the like maladies. All which tables (as some reports) *Hippocrates* transcribed, and so from those drew the Art of Physick. Beasts also have added much to this Art. For one man was not only instructed by another, but learned also much from brute beasts, for they by the only instinct of nature have found out divers herbs, and remedies, by which they freed and preserved themselves from infirmities, which might presently be transferred to mans use. Wherefore considering that such and so many have concurred to bring this Art to perfection, who hereafter dare call in question the excellency thereof? chiefly if he respect the subject thereof, Mans body, a thing more noble than all other Mundane things, and for which the rest were created. Which thing moved *Herophilus* in times past to call Physitians *The hands of the Gods*. For as we by putting forth our hand, do help any man out of the water or mud into which he is fallen: even so we do sustain those that are thrown down from the top of health to the gates of death by violence of diseases, with happy medicins, and as it were by some speciall and divine gift deliver them out of the jaws of death. *Homer* the Prince of Greek Poets affirms that one Physitian is far more worthy than many other men. All Antiquity gave Physitians such honour, that they worshipped them with great veneration as Gods, or the sons of their Gods. For who is it which is not much delighted with the divine force of healthful medicins, with which (we see by dayly experience) Physitians, as armed with *Mercuries* rod, do bring back those languishing souls which are even entring the gates of death? Hence it cometh to passe that the divine Poets of ancient times, as *Orpheus*, and *Museus*, and *Hesiod*, and the most renowned Philosophers, *Pythagoras*, *Plato*, *Aristotle*, *Theophrastus*, *Chrysippus*, *Cato Censorius*, and *Varro*, esteemed nothing more excellent than to excell in the knowledg of Medicins, and to testifie the same by written monuments to Posterity. For what can be more noble and worthy of a generous disposition than to attain to that by the benefit of Physick, that adorned with the ornaments of dignity thou mayest have power over other men, and favoured of Princes, Kings, and Emperours, mayest appoint and prescribe to them those things which are profitable to preserve health, and cure their diseases? But if you look for benefit by sci-

ences;

The Preface.

In what esteem
Physicians have
formerly been.

ences; then know that the professors hereof have beside sufficient gain, acquired much honour and many friends. *Hippocrates* coming to *Abdera* to cure *Democritus* of his madness, not only the men of the City, but also the women, children, and people of every age, sexe and rank, went forth to meet him, giving him with a common consent and loud voice the title of a *Tutelary Deity* and father of their Country. But the *Athenians*, for freeing their country from the plague, with triumphant pompe celebrated playes to his honour, and bountifully set upon his head as if he had been a King, a Crown of gold weighing a 1000. pieces of their golden coin, and erected his statue, for a perpetuall monument of his piety and learning. *Erasistratus* the Nephew of *Aristotle* by his daughter, received, freely given him by *Ptolomy* King of *Egypt*, for the cure of his son, 100. Talents of Gold. The Emperour *Augustus* honoured *Anonius Musa* with a golden statue. *Quintus Stertinius* yearly received out of the Emperours Treasury 12000.500. pieces of gold. In the time of our Grandfathers *Petrus Aponensis* called *Conciliator* was so famous through all *Italy* for his knowledg in Physick, that he could scarce be intreated to come to any man of fashion that was sick, unless he gave him 50. crowns, for every day he was absent from home: but when hee went to cure *Honorius* the Bishop of *Rome*, he received 400. crowns for every day he was absent. Our *French* Chronicles relate in what credit & estimation *James Cotterius* the Physitian was with *Lewis* the 11. King of *France*; for they report he gave him monethly out of his Treasury 10000. crowns. Physick in times past hath been in such esteem with many famous and noble personages, that divers Kings and Princes delighted with the study thereof, and desirous to attain glory and credit thereby, called sundry herbs after their own names. For so *Gentian* took its name of *Gentius* King of *Illyria*; the herb *Lysimachia* of *Lysimachus*, the King of *Macedon*, the *Mithridaticke* herb or *Scordium*, of *Mithridates* the King of *Pontus* & *Bithinia*, *Achilla* of *Achylles*, *Centorie* of *Cbiron* the *Centaure*; *Artemisia* of *Artemisia* the Queen of *Caria*. *Attalus* King of *Pergamus*, *Salomon* of *Judea*, *Evax* of *Arabia*, and *Iuba* the King *Mauritania*, were not only inflamed with a desire of the knowledg of Plants; but either they have written books of it, or for the great commodity of posterity, invented by their skil many choise antidotes compounded of divers simples; neither the desire of learning this noble science is yet altogether extind. As may appear by that *Indian* plant *Tobacco*, called by some the noble herb, *Catherines* herb and *Medices* herb, but commonly the *Queens* herb, because *Catherine Medices* the mother of our Kings, by her singular study and industry made manifest the excellent vertue it hath in curing malign ulcers and wounds, which before was unknown to the *French*. For these worthy men understood that their glory,

thus

Names given
to Plants.

The Preface.

thus fastened and ingrafted into the deep, and as it were ever living roots of plants, would never decay; but should be propagated to all posterity in many succeeding ages, growing up with their sprouting and budding shoots, stalks, flowers and fruits. Neither did these famous men whilst they adorned this part of Physick suffer the other, which treats of the dissection of mans body, be buried in oblivion, and without their knowledg; as instructed with the precepts and learning of the wisest men, how artificiall and unimitable by mortall hand this fabrick of our body is. Neither is it probable that *Apis*, *Osiris* and *Ptolomy* Kings of *Egypt*, *Solomon*, *Alexander* the great, *Mithridates*, *Attalus*, seeing they dedicated themselves wholly to the contemplation of naturall things; neglected the use of *Anatomy*, and being men most desirous to know themselves, to have been ignorant of the structure of their own bodies being the habitations of their souls immortal and made to the Image of God: seeing they observed with certain judgment the different lights of the Sun, Moon and Stars; and passed over so many lands, so many seas, so many regions, so far remote one from another, by wayes so terrible by reason of cold, uncouthness, darkness, by rocks, by fire and sword, with great labour, charge and danger of life, only that they might satisfie their minds thirsting after the knowledg of things; and to have left untouched a thing truly noble, admirable, and most worthy of knowledg, easie to be attained by any and to be acquired without any danger of life, or fortunes.

Seeing there be three parts of that Physick which at this time we professe, *Chirurgery* which by the use of the hand, *Diet* which with a convenient manner of feeding and ordering the body, and *Pharmacy* that by medicins attempt to expell diseases, and preserve health; The prime Physitians do not without reason contend w^{ch} of these may be accounted the chief. Certainly *Herophilus* had *Pharmacy* in such esteem, that he thought medicins were first mixed and administred to the sick by *Apollo* (whom Antiquity thought a great Deity.) And *Pliny* had so good an opinion of *Diet*, that he exclaims; The true remedies and Antidotes against diseases are put into the pot and eaten every day by the poor people. Verily all learned men confesse that the manner of curing which is performed by diet, is much more facile & prosperous, than that which is done by medicins; as those things which sought with much labor and cost are taken with much loathing, and taken are scarce retained, but retained they oft work with much labour and pain: Which things long ago moved *Asclepiades* to exclude the use of medicins, as hurtfull to the stomach. Yet if we will beleeve *Celsus*, neither of these parts merit the preheminnence, but both of them give place to *Chirurgery*. For seeing that fortune is very powerfull in diseases, and the same Meats and Medicins are often good and often vain,

truly

Physick is divided into three parts.

The Preface.

truly it is hard to say, whether the health is recovered by the benefit of Diet and *Pharmacy*, or by the strength of the body. Moreover in those cases, in which we most prevail with medicines, although the profit be more manifest, yet it is evident that health is often sought in vain even by these things, and often recovered without them. As it may be perceived by some troubled with sore eyes, and others with Quartain feavers, who having been long troubled by Physicians are sometimes healed without them. But the effect of Chirurgery as it is very necessary, so it is the most evident amongst all the parts of physick. For who without Chirurgery can hope to cure broken, or luxated parts, who wounds and ulcers, who the falling of the matrix, the stone in the bladder, a member infested with a Gangrene or Sphacele? Besides, this part also is the most ancient; for *Podalirius* and *Machaon* following their Generall *Agamemnon* to the *Trojane* wars, yeelded no small comfort to their fellow Souldiers. Whom notwithstanding *Homer* affirms not to have given any help in the Pestilence, nor in divers other diseases, but only were accustomed to heal wounds by instruments and medicines. And if the difficulty of learning it argue the excellency of the Art, who can doubt but Chirurgery must be the most excellent, seeing that none ought to be accounted a Chirurgeon or which can perform his duty, without the knowledg of Diet and *Pharmacy*? But both the other can perform their parts without Chirurgery if we may beleve *Galen*. But if we consider the matter more neerly according to truth; we shall understand those three parts have a certain common bond and are very near of kindred, so that the one impløres the aid of the other; neither can the Physician do any thing praise-worthy without the conspiracy and joint consent of these three; therefore in ancient times there was but one performer and user of all the three parts. But the multitude of men daily increasing, and on the contrary mans life decreasing, so that it did not seem able to suffice for to learn and exercise all the three, the workmen divided themselves. Wherefore that which happens to any man either by lot, or counsell, that let him follow, maintain and only use, as mindfull how short his life is, and how long the Art.

The excellency
of Chirurgery.

A Table of the Books and Chapters.

Chap.		Pag.
I.	That Chirurgery is,	1
	II. Of chirurgical operations,	ib.

XX.	Of a disease,	} 31
XXI.	Of a symptome,	
XXII.	Of indications,	
XXIII.	Of certain wonderfull and extravagant wayes of curing diseases,	37
XXIV.	Of certain juggling and deceitfull wayes of curing,	ib.

The second book, Of living creatures and of the excellency of man, from 41 to pag. 59.

The third book, Treating of the Anatomy of mans body, 60

I.	The division or partition of mans body,	63
II.	Of the containing parts of the <i>Epigastrium</i> and the preparation to anatomicall administration,	66
III.	Of the outmost skin or cuticle,	67
IV.	Of the true skin,	ib.
V.	Of the fleshy panicle,	68
VI.	Of the fat,	69
VII.	Of the common coat of the muscles,	70
VIII.	What a muscle is, and how many differences there be thereof,	ib.
IX.	Of the parts of a muscle,	73
X.	A more particular inquisition into each part of a muscle,	ib.
XI.	Of the muscles of the <i>Epigastrium</i> , or lower belly,	74
XII.	Of the white-line, and <i>Peritoneum</i> , or rim of the belly,	77
XIII.	Of the <i>Epiploon</i> , <i>Omentum</i> , or <i>Zirbus</i> , that is, the kall,	78
XIV.	Of the ventricle or stomach,	79
XV.	Of the guts,	81
XVI.	Of the mesentery,	83
XVII.	Of the glandules in general; and of the <i>Pancreas</i> , or sweec-bread,	ib.
XVIII.	Of the liver,	84
XIX.	Of the bladder of the gall,	85
XX.	Of the spleen or milte,	86
XXI.	Of the <i>Vena Porta</i> , and gate-vein, and the distribution thereof,	ib.
XXII.	Of the originall of the artery, and the division of the branch, descending to the naturall parts,	87
XXIII.	Of the distribution of the nerves to the naturall parts,	89
XXIV.	The manner of taking out the guts,	89
XXV.	The originall and distribution of the descendēt	

Chap.		Pag.
	hollow-vein,	ib.
XXVI.	Of the kidneys or reins,	90
XXVII.	Of the spermatick vessels,	92
XXVIII.	Of the testicles or stones,	ib.
XXIX.	Of the various bodies or parastars, and of the ejaculatorie vessels, and the glandulous or prostates,	93
XXX.	Of the ureters,	95
XXXI.	Of the bladder,	ib.
XXXII.	Of the yard,	97
XXXIII.	Of the spermatick vessels and testicles in women,	ib.
XXXIV.	Of the womb,	99
XXXV.	Of the coats containing the infant in the womb, and of the navill,	102
XXXVI.	Of the navill,	103

The fourth book, Treating of the small parts contained in the Chest.

I.	What the <i>Thorax</i> or the chest is, into what parts it may be divided, and the nature of these parts,	105
II.	Of the containing and contained parts of the chest,	106
III.	Of the breasts or dugs,	107
IV.	Of the clavicles or collar-bones and ribs,	ib.
V.	The anatomicall administration of the <i>sternon</i> ,	108
VI.	Of the <i>Pleura</i> , or coat investing of the ribs,	109
VII.	Of the <i>Mediastinum</i> ,	ib.
VIII.	Of the <i>Diaphragma</i> , or inmidriffe,	110
IX.	Of the lungs,	ib.
X.	Of the <i>Pericardium</i> or purse of the heart,	111
XI.	Of the heart,	112
XII.	Of the orinces and valves of the heart,	114
XIII.	Of the distribution of the <i>Vena Arteriosa</i> , and the <i>Arteria Venosa</i> ,	ib.
XIV.	Of the distribution of the hollow-vein,	115
XV.	Of the distribution of the nerves or sinews of the sixth conjugation,	119
XVI.	The division of the arteries,	ib.
XVII.	Of the <i>Thymus</i> ,	121
XVIII.	Of the <i>Aspera</i> attery or weazon,	122
XIX.	Of the gullet,	123

The fifth book, Of the animall parts contained in the head.

I.	A generall description of the head,	124
II.	Of the musculous skin of the head, (commonly called the hairy scalp) and of the <i>Pericranium</i> ,	125
III.	Of the sutures,	ib.
IV.	Of the <i>Cranium</i> , or skull,	126
V.	Of the <i>Meninges</i> , that is, the two membranes called <i>Dura Mater</i> and <i>Pia Mater</i> ,	128
VI.	Of the brain,	ib.
VII.	Of the ventricles and mamillary processes of the brain,	130
VIII.	Of the seven conjugations of the nerves of the brain, so called, because they alwayes shew the nerve conjugated and doubled, that is, on each side one,	133
IX.	Of the <i>Rete Mirabile</i> , or wonderfull net, and of the wedg bone,	135
X.	Of the holes of the inner <i>basis</i> of the skull,	136
XI.	Of the perforations of the externall <i>basis</i> of the brain,	ib.
XII.	Of the spinall marrow, or pith of the back,	137

The sixth book, Treating of the muscles and bones, and the other extraneous parts of the body,

I.	Of the bones of the face,	ib.
II.	Of	ib.

A Table of the Books and Chapters.

Chap.	Page	Chap.	Page
II. Of the teeth,	139	XXIII. Of the feaver which happens upon an œdema-	216
III. Of the broad muscle,	140	tous tumor,	216
IV. Of the eye-lids and eye-brows,	142	XXIV. Of <i>Scirrhus</i> or an hard tumor proceeding of	217
V. Of the eyes,	ib.	melancholy,	217
VI. Of the muscles, coats, and humors of the eyes	144	XXV. Of the cure of a <i>Scirrhus</i> ,	218
VII. Of the nose,	145	XXVI. Of a cancer already generated,	ib.
VIII. Of the muscles of the face,	146	XXVII. Of the causes, kinds, and prognosticks of a can-	219
IX. Of the muscles of the lower jaw,	ib.	cer,	219
X. Of the ears and <i>Parotides</i> , or kernels of the ears,	148	XXVIII. Of the cure of a cancer beginning and not yet	220
XI. Of the bone <i>Hyoides</i> , and the muscles thereof,	149	ulcerated,	220
XII. Of the tongue,	150	XXIX. Of the cure of an ulcerated cancer,	ib.
XIII. Of the mouth,	151	XXX. Of the ropick medicins to be applyed an to ul-	221
XIV. Of the <i>Gargareen</i> , or <i>Vvula</i> ,	ib.	cerated, and not ulcerated cancer,	221
XV. Of the <i>Larynx</i> , or throte,	152	XXXI. Of the feaver which happeneth in <i>Scirrhus</i> tu-	223
XVI. Of the neck and parts thereof,	153	mors,	223
XVII. Of the muscles of the neck,	156	XXXII. Of an <i>Aneurisma</i> , that is, the dilataion or spring-	224
XVIII. Of the muscles of the chest and loins,	161	ing of an artery vein or sinew,	224
XIX. Of the muscles of the shoulder blade,	163		
XX. The description of the hand taken in generall,	164		
XXI. The description of the subclavian vein, and first	165		
of the <i>Cephalica</i> or <i>Humeralia</i> ,	165		
XXII. The description of the Axillary vein,	ib.		
XXIII. The distribution of the axillary artery,	166		
XXIV. Of the nerves of the neck, back, and arm,	ib.		
XXV. The description of the bone of the arm, and the	168		
muscles which move it,	168		
XXVI. A description of the bones of the cubit, and the	170		
muscles moving them,	170		
XXVII. A description of the bones of the wrist, after-	171		
wrist and fingers,	171		
XXVIII. Of the muscles which seated in the cubit move	173		
the wand, and with it the hand,	173		
XXIX. Of the muscles of the inside of the hand,	174		
XXX. A description of the leg taken in generall,	175		
XXXI. A description of the crurall vein,	176		
XXXII. A description of the crurall artery,	177		
XXXIII. Of the nerves of the loins, holy-bone, and	178		
thigh,	178		
XXXIV. Of the proper parts of the thigh,	180		
XXXV. Of the muscles moving the thigh,	180		
XXXVI. Of the bones of the leg or shank,	181		
XXXVII. Of the muscles of the legs,	182		
XXXVIII. Of the bones of the foot,	183		
XXXIX. Of the muscles moving the foot,	185		
XL. Of the muscles moving the toes of the feet,	186		
XLI. An epitome or brief recitall of the bones in mans	187		
body,	187		
XLII. An epitome of the names and kinds of compofare	190		
of the bones,	190		

The seventh Book, Of tumors against nature in generall.

I. What a tumor against nature, vulgarly called an Impo-	195
stume, is, and what be the differences thereof,	195
II. Of the generall causes of tumors,	196
III. The signs of impostumes or tumors in generall,	ib.
IV. Of the Prognosticks in impostumes,	197
V. Of the generall cure of tumors against nature,	198
VI. Of the four principall and generall tumors, and of o-	199
ther impostumes which may be reduced to them,	199
VII. Of a Phlegmon,	ib.
VIII. Of the causes and signs of a phlegmon,	200
IX. Of the cure of a true Phlegmon,	ib.
X. Of the cure of an ulcerated phlegmon,	202
XI. Of feavers, and the cure of the leavers which accom-	204
pany a Phlegmon,	204
XII. Of an <i>Erysipelas</i> , or inflammation,	205
XIII. Of the cure of an <i>Erysipelas</i> ,	ib.
XIV. Of the <i>Herpes</i> ; that is, teaters, or ringworms, or such	208
like,	208
XV. Of feavers, which happen upon eryscpelous tumors	ib.
ib.	ib.
XVI. Of an <i>Oedema</i> or cold phlegmatick tumor,	209
XVII. Of the cure of statulent and waterish tumors,	211
XVIII. Of the cure of a statulent and waterish tumor,	ib.
XIX. Of an <i>Atheroma</i> , <i>Steatoma</i> , and <i>Meliceris</i> ,	212
XX. Of the cure of <i>Lupia</i> , that is, wens, or ganglions	213
XXI. Of a <i>Ganglion</i> more particularly so called,	214
XXII. Of the <i>Struna</i> or <i>Seraphula</i> , that is, the Kings	215
cvill,	215

The Eighth book, Of the particular tumors against Nature.

I. Of an <i>Hydrocephalus</i> , or watery tumor which com-	226
monly affects the heads of infants,	226
II. Of a <i>Polypus</i> being an eating disease in the nose,	227
III. Of the <i>Parotides</i> , that is, certain swellings about the	228
ears,	228
IV. Of the <i>Eplulis</i> , or overgrowing of the flesh of the	229
Gums,	229
V. Of the <i>Ravula</i> ,	ib.
VI. Of the swelling of the glandules, or almonds of the	230
throat,	230
VII. Of the inflammation and relaxation in the <i>Vvula</i> or	ib.
<i>Columella</i> ,	ib.
VIII. Of the <i>Angina</i> or squinzy,	232
IX. Of the <i>Bronchocele</i> , or rupture of the throat,	233
X. Of the <i>Purisie</i> ,	234
XI. Of the <i>Dropsie</i> ,	ib.
XII. Of the cure of the dropsie,	235
XIII. Of the tumor and relaxation of the navell,	238
XIV. Of the tumors of the groins and cods called <i>Hernia</i> ,	ib.
that is, Ruptures,	ib.
XV. Of the cure of ruptures,	239
XVI. Of the golden ligature or the <i>Purissim Aureum</i> , as they	242
call it,	242
XVII. Of the cure of other kinds of ruptures,	244
XVIII. Of the falling down of the fundament,	246
XIX. Of the <i>Paronychia</i> ,	ib.
XX. Of the swelling of the knees,	247
XXI. Of the <i>Dracunculum</i> ,	ib.

The ninth Book, Of wounds in generall.

I. What a wounds is, what the kinds and differences	251
thereof are, and from whence they may be drawn, or de-	251
rived,	251
II. Of the causes of wounds,	252
III. Of the signs of wounds,	ib.
IV. Of Prognosticks to be made in wounds,	253
V. Of the cure of wounds in generall,	ib.
VI. Of futures,	255
VII. Of the Flux of blood, which usually happens in	256
wounds,	256
VIII. Of the pain which happens upon wounds,	257
IX. Of convulsion by reason of a wound,	ib.
X. The cure of a convulsion,	258
XI. Of the cure of a convulsion, by sympathy and pain,	259.
ib.	ib.
XII. Of the Palsie,	ib.
XIII. Of the cure of the palsie,	260
XIV. Of swouing,	261
XV. Of <i>Delirium</i> (<i>i.</i>) raving, talking idly, or doting,	ib.

The tenth Book, Of the green and bloody wounds of each part.

I. Of the kinds and differences of a broken skull,	262
II. Of the causes and signs of a broken skull,	264
III. Of the signs of a broken skull, which are manifest to	265
our sense,	265
IV. Of	

A Table of the Books and Chapters.

Chap.	Pag.
IV. Of a fissure being the first kind of a broken skull,	267
V. Of a contusion, which is the second part of a fracture.	267
VI. Of an effraction, depression of the bone, being the third kind of a fracture.	269
VII. Of a feat, being the fourth kind of a broken skull.	271
VIII. Of a <i>Resonans</i> , or counterfissure, being the fifth kind of fracture,	ib.
IX. Of the moving or concussion of the brain,	272
X. Of prognosticks to be made in fractures of the skull,	274
XI. Why when the brain is hurt by a wound of the head, there may follow a convulsion of the opposite part,	275
XII. A convulsion of the deadly signs in the wounds of the head,	275
XIII. Of salutary signs in wounds of the heads,	277
XIV. Of the generall cure of a broken skull, and of the symptoms usually happening thereupon,	ib.
XV. Of the particular cure of wounds of the head, and of the musculous skin,	279
XVI. Of the particular cure of a fracture or broken skull,	281
XVII. Why we use trepaning, in the fractures of the skull,	282
XVIII. A description of trepans,	283
XIX. Of the places of the skull, where you may not apply a trepan,	285
XX. Of the corruption and <i>Caries</i> , or rottenness of the bones of the head,	286
XXI. Of the discommodities which happen to the <i>Crassa meninx</i> , by fractures of the skull,	287
XXII. Of the cure of the brain being shaken or moved,	289
XXIII. Of the wounds of the face,	290
XXIV. Of the wounds of the eyes,	291
XXV. Of the wounds of the cheeks,	293
XXVI. Of the wounds of the nose,	294
XXVII. Of the wounds of the tongue,	ib.
XXVIII. Of the wounds of the ears,	295
XXIX. Of the wounds of the neck and throat,	ib.
XXX. Of the wounds of the chest,	296
XXXI. Of the cure of the wounds of the chest,	297
XXXII. Of the differences, causes, signs, and cure of an <i>Hætick</i> fever,	299
XXXIII. Of the wounds of the <i>Epigastrium</i> , and of the whole lower belly,	301
XXXIV. Of the cure of wounds of the lower belly,	302
XXXV. Of the wounds of the groins, yard and testicles,	303
XXXVI. Of the wounds of the thighs and legs.	ib.
XXXVII. Of the wounds of the nerves, and nervous parts,	ib.
XXXVIII. Of the cure of the wounds of the nervous parts,	304
XXXIX. Of the wounds of the joints,	305
XL. Of the wounds of the Ligaments,	306

Of wounds made by Gunshot, other fiery Engines, and of all sorts of weapons; the eleventh book. The Preface.

The first discourse wherein wounds made by gunshot, are freed from being burnt, or cauterized according to *Vigors* method.

Another discourse of these things, which King *Charles* the ninth, returning from the *Expedition*, and taking of *Rosen*, inquired of me concerning wounds made by gunshot,

I. A division of wounds drawn from the variety of the wounded parts and the bullets which wound,	315
II. Of the signs of wounds made by gunshot,	ib.
III. How these wounds must be ordered at the first dressing,	ib.
IV. A description of fit instruments to draw forth bullets, and other strange bodies,	316
V. What dressing must first be used, after the strange bodies are plucked or drawn out of the wound,	318
VI. How you shall order it at the second dressing,	319
VII. By what means strange bodies, left in at the first dressing, may be drawn forth,	320
VIII. Of indications to be observed in this kind of wounds,	ib.

Chap.	Pag.
IX. What remains for the Chirurgeon to do in this kind of wounds,	321
X. Of ballers which remain in the body, for a long time after the wound is healed up,	322
XI. How to correct the constitutions of the air, so that the noble parts may be strengthened, and the whole body beside,	ib.
XII. Certain memorable histories,	ib.
XIII. An apology concerning wounds made by gunshot,	324
XIV. Another apology, against those who have laboured with new reasons, to prove that wounds made by gunshot are poysoned,	326
XV. How wounds made by arrows differ from those made by gunshot,	327
XVI. Of the diversity of arrows and darts,	ib.
XVII. Of the difference of the wounded parts,	328
XVIII. Of drawing forth arrows,	ib.
XIX. How arrows broken in a wound may be drawn forth,	329
XX. What to be done, when an arrow is left fastened or sticking in a bone,	ib.
XXI. Of poysonous wounds.	ib.

Of Contusions and Gangrenes, the twelfth book.

I. Of a contusion,	330
II. Of the generall cure of great and enormous contusions,	ib.
III. How we must handle contusions when they are joined with a wound,	331
IV. Of those contusions which are without a wound,	ib.
V. By what means the contused part may be freed from the fear, and imminent danger of a gangrene,	ib.
VI. Of that strange kind of symptome which happens upon contusions of the ribs,	332
VII. A discourse of <i>Mummia</i> , or mummy,	ib.
VIII. Of combustions and their differences,	333
IX. Of hot and attractive medicins to be applied to burns,	334
X. Of a gangrene and mortification,	335
XI. Of the generall and particular causes of a gangrene,	ib.
XII. Of the antecedent causes of a gangrene,	ib.
XIII. Of the signs of a gangrene,	336
XIV. Of the prognosticks in gangrenes,	337
XV. Of the generall cure of a gangrene,	ib.
XVI. Of the particular cure of a gangrene,	ib.
XVII. The signs of a perfect <i>necrosis</i> , or mortification,	338
XVIII. Where amputation must be made,	ib.
XIX. How the section or amputation must be performed,	339
XX. How to stanch the bleeding when the member is taken off,	ib.
XXI. How after the blood is stanchd, you must dresse the wounded member,	340
XXII. How you must stop the bleeding, if any of the bound up vessels chance to get loose,	ib.
XXIII. How to perform the residue of the cure of the amputated member,	ib.
XXIV. What just occasion moved the Author to devise this new form of remedy, to stanch the blood after the amputation of a member, and to forsake the common way used almost by all Chirurgeons; which is by application of aduall cauteries,	341
XXV. The practice of the former precepts is declared, together with a memorable history of a certain souldier, whose arm was taken off at the elbow,	342

Of ulcers, fistula's, and haemroids, the thirteenth book.

I. Of the nature, causes and differences of ulcers,	343
II. Of the signs of ulcers,	344
III. Of the Prognosticks of ulcers,	ib.
IV. Of the generall cure of ulcers,	345
V. Of a distempred ulcer,	346
VI. Of an ulcer with pain,	347
VII. Of ulcers, with overgrowing or prouidness of flesh,	ib.
VIII. Of an ulcer putrid and breeding worms,	ib.
IX. Of a fordid ulcer,	348
X. Of a virulent and malign ulcer, which is termed <i>cancer</i> , and of a Chironian ulcer,	ib.
XI. Am	ib.

A Table of the Books and Chapters.

<i>Chap.</i>	<i>pag.</i>	<i>Chap.</i>	<i>pag.</i>
XI. An advertisement to the young Chirurgion touching the distance of times wherein malign ulcers are to be dressed,	349	breeding,	377
XII. How to bind up ulcers.	<i>ib.</i>	XXIX. Of those things that may hinder the generation of a <i>Callus</i> , and how to correct the fault thereof, if it be ill formed,	378
XIII. Of the cure of parricular ulcers, and first of those of the eyes,	350	XXX. Of fomentations which be used in broken bones	379
XIV. Of the <i>Ozena</i> and ulcers of the nose,	<i>ib.</i>	XXXI. Of the fractures of the bones in the feet.	<i>ib.</i>
XV. Of the ulcers of the mouth,	<i>ib.</i>		
XVI. Of the ulcers of the ears,	351	<i>Of Dislocations or Luxations, the sixteenth Book.</i>	
XVII. Of the ulcers of the windpipe, weazon, stomach, and guts,	<i>ib.</i>	I. Of the kinds and manners of dislocations,	379
XVIII. Of the ulcers of the kidneys and bladder,	352	II. Of the differences of dislocations.	380
XIX. Of the ulcers of the womb,	353	III. Of the causes of dislocations,	<i>ib.</i>
XX. Of the varices, and their cure by cutting,	<i>ib.</i>	IV. The signs of dislocations,	<i>ib.</i>
XXI. Of fistula's,	354	V. Of prognosticks to be made upon luxations,	381
XXII. Of the cure of fistula's,	355	VI. Of the generall cure of dislocations,	382
XXIII. Of the fistula's in the fundament,	<i>ib.</i>	VII. The description of certaine engines, serving for the restoring of dislocations,	<i>ib.</i>
XXIV. Of hemorrhoides,	356	VIII. Of the dislocation of the jaw bone,	383
<i>Of Bandages or Ligatures, the fourteenth Book.</i>			
I. Of the differences of bandages,	357	IX. How to set the jaw dislocated forwards on both sides,	384
II. Sheweth the indications and generall precepts of fitting of bandages and ligatures,	<i>ib.</i>	X. Of restoring the jaw dislocated forwards but on one side,	<i>ib.</i>
III. Of the three kinds of bandages necessary in fractures,	358	XI. Of the luxation of the collar bone,	<i>ib.</i>
IV. Of the binding up of fractures associated with a wound,	359	XII. Of the luxation of the spine, or back bone,	385
V. Certain common precepts of the binding up of fractures and luxations,	<i>ib.</i>	XIII. Of the dislocation of the head,	<i>ib.</i>
VI. Of the uses for which ligatures serve,	360	XIV. Of the dislocation of the <i>vertebrae</i> , or rack bones of the neck,	<i>ib.</i>
VII. Of bolsters or compresses,	<i>ib.</i>	XV. Of the dislocated <i>vertebrae</i> of the back.	386
VIII. Of the use of splints, junks, and cases,	361	XVI. How to restore the spine outwardly dislocated,	<i>ib.</i>
<i>Of Fractures, the fifteenth Book.</i>			
I. What a Fracture is, and what the differences thereof are,	361	XVIII. A more particular inquiry of the dislocation of the <i>vertebrae</i> , proceeding from an internall cause,	387
II. Of the signs of a fracture,	362	XVIII. Prognosticks of the dislocated <i>vertebrae</i> of the back,	<i>ib.</i>
III. Prognosticks to be made in fractures,	<i>ib.</i>	XIX. Of the dislocation of the rump,	388
IV. The generall cure of broken and dislocated bones,	363	XX. Of the luxation of the ribs,	<i>ib.</i>
V. By what means you may perform the third intention in curing fractures and dislocations, which is, the hindering and correction of accidents and symptoms,	364	XXI. Of a dislocated shoulder,	<i>ib.</i>
VI. Of the fracture of the nose,	365	XXII. Of the first manner of setting a shoulder, which is with ones fist.	(389)
VII. Of the fracture of the lower jaw,	<i>ib.</i>	XXIII. Of the second manner of restoring a shoulder, that is, with the heel; when as the Patient by reason of pain can neither sit, nor stand.	(390)
VIII. Of the fracture of the clavicle, or collar bone,	366	XXIV. Of the third manner of restoring a shoulder,	<i>ib.</i>
IX. Of the fracture of the shoulder blade,	<i>ib.</i>	XXV. Of the fourth manner of restoring a dislocated shoulder,	(391)
X. Of the fracture and depression of the <i>Sternum</i> , or breast bone,	367	XXVI. Of the fifth manner of putting the shoulder into joint, which is performed by a Ladder,	<i>ib.</i>
XI. Of the fracture of the ribs,	<i>ib.</i>	XXVII. The sixth manner of restoring a shoulder, luxated into the arm-pit,	(392)
XII. Of certain preternaturall affects which ensue upon broken ribs,	368	XXVIII. How to restore a shoulder dislocated forwards,	(394)
XIII. Of the fracture of the <i>vertebrae</i> , or rack bones of the back, and their processes,	369	XXIX. Of the shoulder luxated outwardly,	(395)
XIV. Of the fracture of the holy bone,	<i>ib.</i>	XXX. Of the shoulder dislocated upwards.	<i>ib.</i>
XV. Of the fracture of the rump,	<i>ib.</i>	XXXI. Of the dislocation of the elbow,	<i>ib.</i>
XVI. Of the fracture of the hip, or <i>os ilium</i> ,	<i>ib.</i>	XXXII. How to restore the elbow, dislocated outwardly,	(396)
XVII. Of a fracture of the shoulder, or arm bone,	<i>ib.</i>	XXXIII. Of the dislocation of the elbow to the inside, and of a compleat and uncompleat luxation,	(397)
XVIII. Of the fracture of the cubit, or ell and wand,	370	XXXIV. Of the dislocation of the <i>Styliformis</i> or bodkin-like proccesse of the cubit or ell,	<i>ib.</i>
XIX. Of the fracture of a hand,	<i>ib.</i>	XXXV. Of the dislocation of the wrist,	(398)
XX. Of the fracture of a thigh,	<i>ib.</i>	XXXVI. Of the dislocated bones of the wrist,	<i>ib.</i>
XXI. Of the fracture of the thigh nigh to the joint, or the upper or lower head of the bone,	<i>ib.</i>	XXXVII. Of the dislocated bones of the after-wrist,	389
XXII. Of the fracture of the <i>Patella</i> , or whirle bone of the knee,	<i>ib.</i>	XXXVIII. Of the dislocated finger,	<i>ib.</i>
XXIII. Of a broken leg,	<i>ib.</i>	XXXIX. Of a dislocated thigh, or hip,	<i>ib.</i>
XXIV. Of something to be observed in ligation, when a fracture is associated with a wound,	375	XL. Prognosticks belonging to a dislocated hip,	390
XXV. What was used to the Authors leg after the first dressing,	<i>ib.</i>	XLI. Of the signs of the hip dislocated outwardly, or inwardly,	<i>ib.</i>
XXVI. What may be the cause of the convulsion twichings of broken members,	376	XLII. Of the thigh bone dislocated forwards,	391
XXVII. Certain documents concerning the parts whereon the Patient must necessarily rest, whilst he lyes in his bed,	<i>ib.</i>	XLIII. Of the thigh bone dislocated backwards,	<i>ib.</i>
XXVIII. By what means we may know the <i>Callus</i> is a		XLIV. Of restoring the thigh bone dislocated inwards,	392
		XLV. Of restoring the thigh dislocated outwardly,	393
		XLVI. Of restoring the thigh dislocated forwards,	394
		XLVII. Of restoring the thigh dislocated backwards,	<i>ib.</i>
		XLVIII. Of the dislocation of the whirle bone of the knee,	<i>ib.</i>
		XLIX. Of the dislocated knee,	395
		L. Of	<i>ib.</i>

A Table of the Books and Chapters.

Chap.	Pag.
L. Of a knee dislocated forwards,	395.
LI. Of the separation of the greater and lesser focile, <i>ib.</i>	
LII. Of the leg bone or greater focile dislocated, and divided from the pasterbone, <i>ib.</i>	
LIII. Of the dislocation of the heel,	396
LIV. Of the symptoms which follow upon the contusion of the heel, <i>ib.</i>	
LV. Of the dislocated paster, or ankle bone,	397
LVI. Of the dislocation of the Instep and back of the foot, <i>ib.</i>	
LVII. Of the dislocation of the toes, <i>ib.</i>	
LVIII. Of the symptoms, and accidents which may befall a broken or dislocated member,	398

Of divers other proternaturall affects whose cure is commonly performed by Surgery, The seventeenth book.

I. Of an Alopecia, or the falling away of the hairs of the head,	399
II. Of the tinea or scald head, <i>ib.</i>	
III. Of the vertigo or giddinesse,	401
IV. Of the hemicrania or megrim, <i>ib.</i>	
V. Of certain affects of the eyes, and first of staying up the upper eye-lid when it is too lax,	402
VI. Of lagophthalmus, or the hare-eye,	403
VII. Of the Chalazion, or hail stone, and the Hordeolum, or barley corn of the eye-lids, <i>ib.</i>	
VIII. Of the Hydatis, or fatnesse of the eye-lids, <i>ib.</i>	
IX. Of the eye-lids fastened or glued together,	404
X. Of the itching of the eye-lids, <i>ib.</i>	
XI. Of lippitudo, or blear-eyes,	405
XII. Of the Ophthalmia, or inflammation of the eyes, <i>ib.</i>	
XIII. Of the proptosis, that is, the falling or the starting forth of the eye, and of the phibisis and camosis of the same,	406
XIV. Of the ungula, or web, <i>ib.</i>	
XV. Of the agilops, fistula lacrymosa, or weeping fistula of the eye,	407
XVI. Of the staphyloma or grape-like swelling,	408
XVII. Of the hypopyon, that is, the suppurate or putrid eye,	409
XVIII. Of the mydriasis, or dilation of the pupil of the eye, <i>ib.</i>	
XIX. Of a cataract <i>ib.</i>	
XX. Of the Physicall cure of a beginning cataract,	410
XXI. By what signs ripe and curable cataracts, may be discovered from unripe and uncurable ones,	411
XXII. Of the couching a cataract, <i>ib.</i>	
XXIII. Of the stopping of the passage of the cats, and of the falling of things thereinto,	412
XXIV. Of getting little bones, and such like things out of the jaws and throat,	413
XXV. Of the tooth ach, <i>ib.</i>	
XXVI. Of other affects of the teeth,	414
XXVII. Of drawing of teeth,	415
XXVIII. Of cleansing the teeth,	417
XXIX. Of the impediment and contraction of the tongue, <i>ib.</i>	
XXX. Of superfluous fingers, and such as stick together, <i>ib.</i>	
XXXI. Of the too short a prepuce, and of such as have been circumcised,	418
XXXII. Of phimosis, and paraphimosis, that is so great a constriction of the prepuce about the the glans or nut that it cannot be bared or uncovered at pleasure, <i>ib.</i>	
XXXIII. Of those whose glans is not rightly perforated, and of the too short or too strait ligament bridle, or cord of the yard,	419
XXXIV. Of the causes of the stone, <i>ib.</i>	
XXXV. Of the signs of the stone in the kidneys and bladder,	420
XXXVI. Prognosticks in the stone,	421
XXXVII. VVhat cure is to be used when we fear the stone,	422
XXXVIII. What is to be done when the stone falleth out of the kidney into the ureter,	423
XXXIX. What must be done the stone being fallen into the neck of the bladder,	424
XL. What course must be taken, if the stone sticking in the ureter, or urinary passage, cannot be gotten out by the forsmentioned art,	425

Chap.	Pag.
XLI. What manner of section is to be made, when a stone is in a boyes bladder,	426
XLII. How to cut men, for the taking out of the stone in the bladder,	427
XLIII. What cure must be used to the wound when the stone is taken forth,	431
XLIV. How to lay the patient after the stone is taken away,	432
XLV. How to cure the wound made by the incision, <i>ib.</i>	
XLVI. What cure is to be used to ulcers, when as the urine flows through them, long after the stone is drawn out,	433
XLVII. How to take stones out of womens bladders,	433
XLVIII. Of the suppression of the urine by internall causes,	434
XLIX. A digression concerning the purging of such as are unprofitable in the whole body by the urine,	435
L. By what externall causes the urine is suppress, and prognosticks concerning the suppression thereof, <i>ib.</i>	
LI. Of bloody urine,	436
LII. Of the signs of the ulcerated Kidneys, <i>ib.</i>	
LIII. Of the signs of the ulcerated bladder,	437
LIV. Prognosticks of the ulcerated reins and bladder, <i>ib.</i>	
LV. What cure must be used in the suppression of the urine,	437
LVI. Of the diabete, or inability to hold the urine,	438
LVII. Of the strangury, <i>ib.</i>	
LVIII. Of the colick,	439
LIX. Of phlebotomy or blood-letting,	441
LX. How to open a vein or draw blood from thence,	442
LXI. Of cupping-glasses or ventoses,	443
LXII. Of leeches and their use,	445

Of the Gout; the eighteenth book.

I. Of the description of the gout,	446
II. Of the occult causes of the gout, <i>ib.</i>	
III. Of the manifest causes of the gout,	448
IV. Out of what part the matter of the gout may flow down upon the joints, <i>ib.</i>	
V. The signs of the Arthritick humor flowing from the brain,	449
VI. The signs of a gouty humor, proceeding from the liver, <i>ib.</i>	
VII. By what signs we may understand this or that humor, to accompany the gout in malignity, <i>ib.</i>	
VIII. Prognosticks in the gout,	450
IX. The generall method of preventing and curing the gout,	451
X. Of vomiting,	452
XI. The other generall remedies for the gout, <i>ib.</i>	
XII. What diet is convenient for such as have the gout,	453
XIII. How to strengthen the joints,	454
XIV. Of the palliative cure of the gout, and the material causes thereof,	455
XV. Of locall medicins that may be used to a cold gout,	456
XVI. Of locall medicins to be applied to a hot or sanguine gout,	458
XVII. Of locall medicins for a choleric gout, <i>ib.</i>	
XVIII. What remedies must be used in pains of the joints proceeding of a distemper only, without matter, <i>ib.</i>	
XIX. What is to be done after the fit of the gout is over, <i>ib.</i>	
XX. Of the tophi, or knots which grow at the joints of such as are troubled with the gout,	461
XXI. Of the flatulencies contained in the joints, and counterfeiting true gout, and of the remedies to be used thereto,	462
XXII. Of the Ischias, hip gout, or Sciatica, <i>ib.</i>	
XXIII. The cure of the sciatica,	463
XXIV. Of the statulent convulsion, or convulsive contraction, which is commonly called by the French Gout cramp, and by the English the cramp,	464

A Table of the Books and Chapters.

The nineteenth Book.

Chap.		pag.
I.	Of the <i>lues venerea</i> , and those symptoms which happen by the means thereof,	464
II.	Of the causes of the <i>lues venerea</i> ,	465
III.	In what humor the malignity of the <i>lues venerea</i> relides,	466
IV.	Of the signs of the <i>lues venerea</i> ,	467
V.	Of prognosticks,	<i>ib.</i>
VI.	How many and by what means there are to oppugn this disease,	468
VII.	How to make choice of the wood <i>Guaicum</i> ,	<i>ib.</i>
VIII.	Of the preparation of the decoction of <i>Guaicum</i> ,	469,
IX.	Of the second manner of curing the <i>lues venerea</i> which is performed by friction or unction,	470
X.	Of the choice preparation and mixing of <i>Hydrargyrum</i> ,	<i>ib.</i>
XI.	How to use the unction,	471
XII.	What cautions to be used in rubbing, or anointing the Patient,	472
XIII.	Of the third manner of cure, which is performed by cerates and emplasters, as substitutes of unctions,	473
XIV.	Of the fourth manner of curing the <i>lues venerea</i> ,	475
XV.	Of the cure of the symptoms, or symptomatique affects of the <i>lues venerea</i> , and first of the ulcers of the yard,	<i>ib.</i>
XVI.	How a <i>Gonorrhœa</i> differeth from a virulent strangury,	476
XVII.	Of the causes and difference of the scalding, or sharpness of the urine,	<i>ib.</i>
XVIII.	Prognosticks in a virulent strangury,	477
XIX.	The chiefe heads of curing a <i>Gonorrhœa</i> ,	478
XX.	The general cure both of the scalding of the water, and the virulent strangury,	<i>ib.</i>
XXI.	Of the proper cure of a virulent strangury,	<i>ib.</i>
XXII.	Of caruncles, or fleshy excrescences which sometimes happen to grow in the <i>urethra</i> by the heat or scalding of the urin.	479
XXIII.	What other remedies shall be used to caruncles occasioned by the <i>lues venerea</i> ,	481
XXIV.	Of venereall <i>Buboes</i> , or swellings in the groins,	482
XXV.	Of the <i>exostosis</i> , bunches, or knots growing upon the bones, by reason of the <i>lues venerea</i> ,	483
XXVI.	Why the bones become rotten, and by what means it may be perceived,	<i>ib.</i>
XXVII.	Of actual and potentiall cauterics,	488
XXVIII.	Of the vulnerary potion,	<i>ib.</i>
XXIX.	Of tetters, ring-worms, or chops, occasioned by the <i>lues venerea</i> ,	489
XXX.	Of curing the <i>lues venerea</i> in infants and little children,	<i>ib.</i>

The twentieth Book, Of the small pox and meazles; as also of worms and the leprosie, from 491. to 503.

491

The one and twentieth Book, Of poysons, and of the biting, and stinging of a mad dog, and the biting and stinging of other venomous creatures, from pag. 504. to pag. 534.

504

The two and twentieth Book, Of the Plague.

I.	The description of the plague,	535
II.	Of the divine causes of an extraordinary plague,	<i>ib.</i>
III.	Of the naturall causes of the plague,	536
IV.	Of the preparation to humors to putrefaction, and admission of pestiferous impressions,	537
V.	What signes in the air and earth prognosticate a plague,	538
VI.	By using what cautions in air and diet, one may prevent the plague,	539
VII.	Of the cordiall remedies by which we may pre-	

Chap.

		pag.
	serve our bodies in fear of the plague, and cure those already infected therewith,	<i>ib.</i>
VIII.	Of locall medicins to be applied outwardly,	542
IX.	Of other things to be observed for prevention, in fear of the plague,	544
X.	Of the office of Magistrates in time of the plague,	<i>ib.</i>
XI.	What caution must be used in choosing Physicians, Apothecaries, and Surgeons, who may have care of such as are taken with the plague,	545
XII.	How such as undertake the cure of the plague ought to arm themselves,	<i>ib.</i>
XIII.	Of the signs of such as are infected with the plague,	546
XIV.	What signs in the plague are mortall,	547
XV.	Signs of the plague coming by contagion of the air without any fault of the humours,	548
XVI.	Signs of the plague drawn into the body by the fault and putrefaction of humours,	549
XVII.	Of the prognostication that is to be instituted in the plague,	549
XVIII.	How a pestilent fever comes to be bred in us,	550
XIX.	Into what place the Patient ought to betake himselfe so soone as he finds himselfe infected,	551
XX.	What diet ought to be observed, and first of the choice of meat,	552
XXI.	What drink the Patient infected ought to use,	553
XXII.	Of antidotes to be used in the plague,	555
XXIII.	Of Epithems to be used for the strengthening of the principal parts,	556
XXIV.	Whether purging and blood-letting be necessary in the beginning of pestilent diseases,	557
XXV.	Of purging medicins in a pestilent disease,	558
XXVI.	Of many symptoms which happen together with the plague, and first of the pain of the head,	560
XXVII.	Of the heat of the kidneys,	561
XXVIII.	Of the eruptions and spots, which commonly are called by the name of purples, and tokens,	<i>ib.</i>
XXIX.	Of the cure of eruptions and spots,	562
XXX.	Of a pestilent <i>Bubo</i> or plague sore,	563
XXXI.	Of the cure of <i>Buboes</i> or plague sores,	<i>ib.</i>
XXXII.	Of the nature, causes, and signes of a pestilent carbuncle,	566
XXXIII.	What prognosticks may be made in pestilent buboes and carbuncles	<i>ib.</i>
XXXIV.	Of the cure of a pestilent carbuncle,	568
XXXV.	Of the itching and inflammation happening in pestilent ulcers, and how to cicatrize them,	569
XXXVI.	Of sundry kinds of evacuations, and first of sweating and vomiting,	<i>ib.</i>
XXXVII.	Of spitting, salivation, sneezing, belching, hicketing, and making water,	570
XXXVIII.	Of the menstruell and hæmorrhoidall purgation,	571
XXXIX.	Of procuring evacuation by stool, or a flux of the belly,	572
XL.	Of stopping the flux of the belly,	<i>ib.</i>
XLI.	Of evacuation by insensible transpiration,	574
XLII.	How to cure infants and children taken with the plague,	<i>ib.</i>

The three and twentieth Book, Of the meanes and manner to repair or supply the defects of mans Body.

I.	How the losse of the naturall or true eye may be covered, hidden, or shadowed,	576
II.	By what meanes a part of the nose that is cut off, may be restored; or how in stead of the nose that is cut off, another counterfeit nose may be fastned, or placed in the stead,	577
III.	Of the placing of teeth artificially made in stead of those that are lost or wanting,	578
IV.	Of filling the hollownesse of the palat,	<i>ib.</i>
V.	How to help such as cannot speak by reason of the losse of some part of the tongue,	580
VI.	Of covering and repairing certaine defects or defaults in the face,	<i>ib.</i>
VII.	Of the defects of the ears,	581
VIII.	Of amending the deformity of such as are crook-back't,	<i>ib.</i>
IX.	How	

A Table of the Books and Chapters.

Chap.	Pag.
IX. How to relieve such as have their urine flow from them against their wils, and such as want their yards,	582
X. By what means the perished function or action of a thumb or finger may be corrected and amended,	583
XI. Of the helping those that are <i>vari</i> or <i>valgi</i> , crook-legged, or crook footed, inwards, or outwards,	584
XII. By what means arms, legs, and hands may be made by art, and placed in the stead of naturall arms, legs, or hands, that are cut off, and lost,	585
XIII. Of amending or helping lameness or halting,	589

Of the Generation of Man, the four and twentieth Book.

I. Why the generative parts are endued with great pleasure,	590
II. Of what qualitie the seed is, whereof the male, and whereof the female is engendred,	592
III. What is the cause why females of all brute beasts, being great with young, do neither desire nor admit the males, untill they have brought forth their young,	592
IV. What things are to be observed, as necessary unto generation in the time of copulation,	593
V. By what signs it may be known, whether the woman have conceived or nor,	<i>ib.</i>
VI. That the womb so soon as it hath received the seed, is presently contracted or drawn together,	594
VII. Of the generation of the navell,	<i>ib.</i>
VIII. Of the umbilicall vessels, or the vessels belonging to the navell,	595
IX. Of the ebullition or swelling of the seed in the womb, and of the concrecion of the bubbles or bladders, or the three principall entralls,	<i>ib.</i>
X. Of the third bubble or bladder, wherein the head and the brain is formed,	596
XI. Of the life or soul,	597
XII. Of the naturall excrements in generall, and especially of those that the child or infant bring in the womb excludeth,	599
XIII. With what travell the child is brought into the world, and of the cause of this travell,	601
XIV. Of the situation of the infant in the womb,	<i>ib.</i>
XV. Which is the legitimate and naturall, and which the illegitimate or unnaturall time of childbirth,	602
XVI. Signs of the birth at hand,	603
XVII. What is to be done presently after the child is born,	604
XVIII. How to pull away the secundine or after-birth,	606

XIX. What things must be given to the infant by the mouth, before he be permitted to suck the teat or dug,	<i>ib.</i>
XX. That mothers ought to give suck to their owne children,	607
XXI. Of the choise of nurses,	<i>ib.</i>
XXII. What diet the nurse ought to use, and in what situation she ought to place the infant in the cradle,	609
XXIII. How to make pap for children,	610
XXIV. Of the weaning of children,	611
XXV. By what signes it may be known whether the child in the womb be dead or alive,	612
XXVI. Of the chirurgicall extractions of the child from the womb, either dead or alive,	<i>ib.</i>
XXVII. What must be done unto the woman in travell, presently after her deliverance,	615
XXVIII. What care must be used to the dugs and teats of those that are brought to bed,	616
XXIX. What the causes of difficult and painfull travell in childbirth are,	617
XXX. The cause of abortioun or untimely birth,	618
XXXI. How to preserve the infant in the womb when the mother is dead,	619
XXXII. Of superfetation,	620
XXXIII. Of the tumor called <i>mola</i> , or a mole growing in the womb of women,	<i>ib.</i>
XXXIV. How to discern a true conception from a false conception or <i>mola</i> ,	621
XXXV. What cure must be used to the <i>mola</i> ,	623

Chap.	Pag.
XXXVI. Of tumors or swellings happening to the <i>pancreas</i> or sweet-bread, and the whole mesenteric,	624
XXXVII. Of the cause of barrenesse in women,	625
XXXVIII. Of the barrenesse or unfruitfulness of women,	626
XXIX. The signs of a distempered womb,	627
XL. Of the falling down, or perversion, or turning of the womb,	628
XLI. The cure of the falling down of the womb,	<i>ib.</i>
XLII. Of the tunicle or membrane called <i>hymen</i> ,	630
XLIII. A memorable history of the membrane called <i>hymen</i> ,	631
XLIV. Of the strangulation of the womb,	632
XLV. The signes of imminent strangulation of the womb,	633
XLVI. How to know whether the woman be dead in the strangulation of the womb, or not,	<i>ib.</i>
XLVII. How to know whether the strangulation of the womb comes of the suppression of the flowers, or the corruption of the seed,	634
XLVIII. Of the cure of the strangulation of the womb,	<i>ib.</i>
XLIX. Of womens monthly flux or courses,	636
L. The causes of the monthly flux or courses,	637
LI. The causes of the suppression of the courses or menstruall flux,	638
LII. What accidents follow the suppression or stopping of the monthly flux or flowers,	<i>ib.</i>
LIII. Of provoking the flowers or courses,	639
LIV. Of the signes of the approaching of the menstruall flux,	<i>ib.</i>
LV. Accidents follow immoderate fluxes of the flowers or courses,	640
LVI. Of stopping the immoderate flowing of the flowers and courses,	641
LVII. Of locall medicines to be used against the immoderate flowing of the courses,	<i>ib.</i>
LVIII. Of women fluxes or the whites,	<i>ib.</i>
LIX. Of the causes of the whites,	642
LX. The cure of the whites,	<i>ib.</i>
LXI. Of the <i>hemorrhoides</i> and warts of the neck of the womb,	643
LXII. Of the cure of the warts that are in the neck of the womb,	644
LXIII. Of chaps, and those wrinkled and hard excrescences, which the greeks call <i>condylomata</i> ,	645
LXIV. Of the itching of the womb,	<i>ib.</i>
LXV. Of the relaxation of the great gut, or intestine, which happeneth to women,	646
LXVI. Of the relaxation of the navell in children,	<i>ib.</i>
LXVII. Of the pain that children have in breeding of teeth,	<i>ib.</i>

Of Monsters and prodigies, the five and twentieth Book, from pag. 648. to pag. 695.

Of the faculties of simple medicines as also of their composition and use, the six and twentieth book.

I. What a medicine is, and how it differeth from nourishment,	696
II. The differences of medicins in their matter and substance,	<i>ib.</i>
III. The difference of simples in their qualities and effects,	697
IV. Of the second faculties of medicines,	698
V. Of the third faculties of medicines,	699
VI. Of the fourth facultie of medicines,	<i>ib.</i>
VII. Of tastes,	700
VIII. Of the preparation of medicinaes,	701
IX. Of repelling, or repercussive medicines,	702
X. Of attractive medicines,	703
XI. Of resolving medicines,	704
XII. Of suppuratives,	705
XIII. Of mollifying things,	<i>ib.</i>
XIV. Of deterfives, or mundificatives,	706
XV. Of farcoticks,	707
XVI. Of epuloricks, or skinning medicines,	<i>ib.</i>
XVII. Of agglutinatives,	708
XVIII. Of	<i>ib.</i>

A Table of the Books and Chapters.

XVIII. Of pyroticks, or caustick medicines,	708	there be,	735
XX Or anodynes, or such as mitigate or assuage paine,	709	II. Of the matter and form of fornaces,	ib.
XX. Of the composition and use of medicines,	710	III. Of vessels fit for distillation,	736
XXI. Of the weight and measures, and the notes of both of them,	711	IV. What things are to be considered in distillation,	ib.
XXII. Of Clysters,	ib.	V. Of what fashion the vessels for the distilling of waters, ought to be,	737
XXIII. Of suppositories, nodules, and pessaries,	713	VI. How the materials must be prepared before distillation,	738
XXIV. Of oils,	714	VII. Of the art of distilling of waters,	739
XXV. Of liniments,	715	VIII. How to distill <i>aqua vite</i> , or the spirits of wine,	740
XXVI. Of ointments,	ib.	IX. Of the manner of rectifying, that is, how to increase the strength of waters, that have been once distilled,	741
XXVII. Of ceras and emplasters,	717	X. Of distillation by filtering	ib.
XXVIII. Of cataplasms and pultices,	720	XI. What and how many wayes there are to make oils,	742
XXIX. Of fomentations,	ib.	XII. Of extracting of oils of vegetables by distillation,	ib.
XXX. Of embrocations,	721	XIII. Another manner how to draw the essence and spirits of herbs, flowers, seeds, and spices, as also of rubarb, agarick, turbith, hermodactyls, and other purgers,	744
XXXI. Of epithems,	722	XIV. How to extract oil out of gums, condensed juices, and rosins, as also out of some woods,	ib.
XXXII. Of potentiall cauterics,	723	XV. Of extracting of oils out of the harder sorts of gums, as myrrh, mastick, frankincense, and the like,	ib.
XXXIII. Of vesicatories,	724	XVI. The making of oil of vitrioll,	746
XXXIV. Of <i>collyria</i> ,	ib.	XVII. A table or catalogue of medicines and instruments serving for the cure of diseases,	747
XXXV. Of errhines, and sternutatories,	725		
XXXVI. Of apophlegmatisms, or masticatories,	ib.		
XXXVII. Of gargarisms,	726		
XXXVIII. Of dentifrices,	727		
XXXIX. Of baggi, or quilts,	ib.		
XL. Of fumigations,	728		
XLI. Of a particular, or halfe bath,	ib.		
XLII. Of baths,	731		
XLIII. Of stoves, or hot-houses,	731		
XLIV. Of <i>faci</i> , that is, washes, and such things for the smoothing and beautifying of the skin,	ib.		
XLV. Of the <i>gutta rosacea</i> , or a fiery face,	733		
XLVI. To black or colour the hair,	734		
XLVII. Of <i>Pistolhra</i> , or depilatories, and also of sweet waters,	ib.		

Of Distillation, the seven and twentieth Book.

I. What distillation is, and how many kindes thereof

How to make reports, and to embalm the dead, the eight and twentieth Book.

The nine and twentieth Book, A Treatise containing divers voyages.

A Table of the Chapters of the three Tracts.

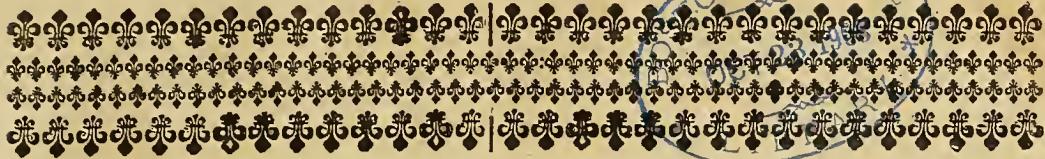

<i>Chap.</i>	<i>pag.</i>	<i>Chap.</i>	<i>pag.</i>
I. Reckons up the branches or propagations of the <i>vena porta</i> , or the gate-vein, and explains an aphorism of <i>Hippocrates</i> , that makes very much to the purpose,	1	great Artery, and the propagation thereof through the middle and lowest bellies,	ib.
II. Treats of the superior, or ascendent trunk of the <i>vena cava</i> , or hollow vein, and the branches which it scatters through the head,	5	IV. The propagations of the outer Iliacall branches which are distributed through the <i>crus</i> , or great foot, containing the thigh, leg, and foot,	30
III. Shews how the axillary vein is distributed through the arm,	9	An explanation of the Table of the Arteries,	32
IV. Explains the lower, or descendent trunk of the hollow vein,	11		
V. Reckons up the propagations, and branches of the outer Iliacall branch disseminated through the <i>crus</i> , or great foot, that reaches from the lower part of the buttock to the end of the toes,	14		
An explanation of the Table of the Veins,	17		

The second Treatise concerning the Arteries.

I. Shews the upper or ascendent trunk of the great Artery, with its propagations that are distributed through the head, 21
 II. Declares the history of the axillary artery being distributed through the arm, 23
 III. Shews the inferiour or descendent trunk of the

The third Treatise concerning the Nerves.

I. Of the nerves of the brain, 35
 II. Concerning the nerves of the spinall marrow properly so called, and first of those of the rack bones of the neck, 40
 III. Concerning the nerves of the marrow of the rack bones of the chest, 42
 IV. Concerning the marrow of the rack bones of the loines, 43
 V. Concerning the nerves of the marrow of *Os sacrum* or the great bone, 44
 VI. Concerning the nerves which are distributed through the arms, 45
 VII. Of the nerves that are distributed through the *crura*, or thighs, legs, and feet, 47
 An explanation of the two Tables of the Nerves, 49 & 50

CHIRURGERY.

CHAP. I.

What Chirurgery is.

CHIRURGERY is an Art, which teacheth the way by reason, how by the operation of the hand we may cure, prevent, and mitigate diseases, which accidentally happen unto us. Others have thought good to describe it otherwise; as that, It is that part of Physick which undertaketh the cure of Diseases by the sole industry of the Hand: as, by cutting, burning, sawing off, uniting fractures, restoring dislocations, and performing other works, of which we shall hereafter treat. Chirurgery also is thus defined by the Author of the *Medicinall Definitions*; The quick motion of an intrepid hand

The definition of Chirurgery.

joyned with experience; or, an artificiall action by the hand used in Physick, for some convenient intent. Yet none must think to attain to any great perfection in this Art, without the help of the other two parts of Physick; I say, of Diet and Pharmacie, and the divers applications of proper Medicines, respecting the condition of the Causes, Diseases, Symptoms, and the like circumstances, which comprehended under the names of things naturall, not naturall, and besides nature, (as they commonly call them) we intend to describe in their proper place. But if any reply, that there be many which do the works of Chirurgery, without any knowledg of such like things, who notwithstanding have cured desperate Diseases with happy success: Let them take this for an answer, That such things happen rather by chance, than by the industry of the Art; and that they are not provident that commit themselves to such. Because that for some one happy chance, a thousand dangerous errors happen afterwards, as *Galen* (in divers places of his Method) speaks against the Empericks. Wherefore seeing we have set down Chirurgery to be a diligent operation of the hands, strengthened by the assistance of Diet and Pharmacy, we will now shew what, and of what nature the operations of it are.

What necessary for a Chirurgeon.

CHAP. II.

Of Chirurgicall Operations.

FIVE things are proper to the duty of a Chirurgeon; To take away that which is superfluous; to restore to their places such things as are displaced; to separate those things which are joyned together; to joyn those which are separated; and to supply the defects of nature. Thou shalt far more easily and happily attain to the knowledg of these things by long use and much exercise, than by much reading of Books, or daily hearing of Teachers. For speech, how perspicuous and elegant soever it be, cannot so vively express any thing, as that which is subjected to the faithfull eyes and hands.

The nature of a Chirurgeon.

Experience more necessary for a Chirurgeon, than Art.

Examples of taking away that which is superfluous.

We have examples of taking away that which abounds in the Amputation or cutting off a finger, if any have six on one hand, or any other monstrous member that may grow out: in the lopping off a putrefied part inwardly corrupted; in the extraction of a dead child, the secundine, mole, or such like bodies out of a womans womb: In taking down of all Tumors, as Wens, Warts, Polypus, Cancers, and fleshy excrescences of the like nature; in the pulling forth of bullets, of pieces of maile, of darts, arrows, shells, splinters, and of all kind of weapons in what part of the body soever they be. And he taketh away that which redounds, which plucks away the hairs of the ey-lids which trouble the ey by their turning in towards it: who cuts away the web, possessing all the * *Adnata*, and part of the * *Cornea*: who letteth forth suppurated matter: who taketh out stones in what part soever of the body they grow; who puls out a rotten or otherwise hurtfull rooth; or cuts a nail that runs into the flesh: who cuts away part of the *Vvula*, or hairs that grow on the ey-lids: who taketh off a Cataract; who cuts the navill or foreskin of a childe newly born; or the skinny caruncles of womens privities.

* Two tunicles of the eys.

Examples of replacing.

Examples of placing those things which are out of their naturall site, are manifest in restoring dislocated bones; in re-placing of the guts and kall fallen into the cods, or out of the navill or belly by a wound; or of the falling down of the womb, fundament, or great gut, or the eye hanging out of its circle, or proper place.

Example of separating things joined together.

But we may take examples of disjoyning those things which are continued; from the fingers growing together, either by some chance, as burning; or by the imbecillity of the forming faculty: by the disjunction of the membrane called *Hymen*, or any other troubling the neck of the womb; by dissection of the ligament of the tongue, which hinders children from sucking and speaking, and of that which hinders the *Glans* from being uncovered of the foreskin; by the division of a varicous vein, or of a half cut nerve or tendon, causing convulsion; by the division of the membrane stopping the auditory passage, the nose, mouth, or fundament, or the stubborn sticking together of the hairs of the ey-lids. Refer to this place all the works done by Causticks, the Saw, Trepan, Lancet, Cupping-glasses, Incision-knife, Leeches, either for evacuation, derivation, or revulsion sake.

Examples of uniting things disjoined.

The Chirurgeon draws together things separated, which healeth wounds by stitching them, by bolstering, binding, giving rest to, and fit placing the part: which repairs fractures; restoring luxated parts: who by binding the vessel, stayeth the violent effusion of blood: who cicatriceth cloven lips, commonly called Hare-lips: who reduceth to equality the cavities of Ulcers and Fistula's.

Examples of supplying defects.

But he repairs those things which are defective either from the infancy, or afterwards by accident, as much as Art and Nature will suffer; who sets on an ear, an ey, a nose, one or more teeth; who fills the hollownes of the palat eaten by the Pox, with a thin plate of gold or silver, or such like; who supplies the defect of the tongue in part cut off, by some new addition; who fastens to a hand, an arm, or leg with fit ligaments, workmanlike: who fits a doublet bumbasted, or made with iron plates to make the body streight; who fills a shoo too big with cork, or fastens a stocking or sock to a lame mans girdle to help his gate. We will treat more fully of all these in our following Work. But in performing those things with the hands, we cannot but cause pain: (for who can without pain cut off an arm, or leg, divide and tear asunder the neck of the bladder, restore bones put out of their places, open Ulcers, bind up wounds, and apply cauterics, and do such like?) notwithstanding the matter often comes to that pass, that unless we use a judicious hand, we must either die, or lead the remnant of our lives in perpetuall misery. Who therefore can justly abhor a Chirurgeon for this, or accuse him of cruelty? or desire they may be served, as in ancient times the Romans served *Archagatus*, who at the first made him free of the City; but presently after, because he did somewhat too cruelly burn, cut, and perform the other works of a good Chirurgeon, they drew him from his house into the *Campus Martius*, and there stoned him to death, as we read it recorded by *Sextus Cheronæus*, *Plutarch's* nephew by his Daughter. Truly it was an inhumane kind of ingratitude, so cruelly to murder a man intent to the works of so necessary an Art. But the Senate could not approve the act, wherefore to expiate the crime as well as then they could, they made his Statue in Gold, placed it in *Æsculapius* his Temple, and dedicated it to his perpetuall memory. For my part, I very well like that saying of *Celsus*: A Chirurgeon must have a strong, stable, and intrepid hand, and a mind resolute and merciles; so that to heal him he taketh in hand, he be not moved to make more haste than the thing requires; or to cut less than is needfull; but which doth all things as if he were nothing affected with their cries; not giving heed to the judgment of the vain common people, who speak ill of Chirurgeons because of their ignorance.

Archagatus the Chirurgeon.

In *præfat. lib. 7.*

The properties of a good Chirurgeon.

CHAP. III.

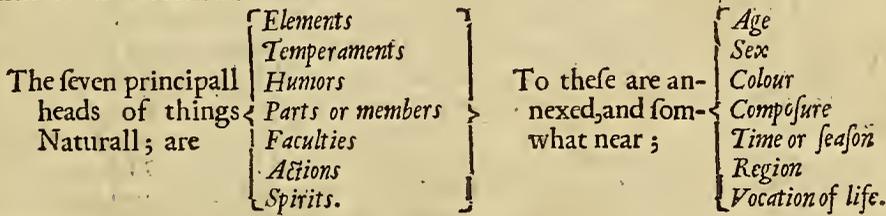

Of things Naturall.

That the Chirurgeon may rightly, and according to Art perform the foresaid works, he must set before his eyes certain Indications of working: Otherwise he is like to become an Emperick, whom no Art, no certain reason, but only a blind temerity of fortune moves to boldness and action. These Indications of actions are drawn from things (as they call them) naturall, not naturall, and besides nature, and their adjuncts, as it is singularly delivered of the Ancients, being men of an excellent understanding. Wherefore we will prosecute according to that order, all the speculation of this Art of ours. First therefore things Naturall are so termed, because they constitute and contain the nature of mans body, which wholly depends of the mixture and temperament of the four first bodies, as it is shewed by *Hippocrates* in his book *de Natura humana*: wherefore the consideration thereof belongs to that part of Physick, which is named *Physiologia*; as the examination of things not naturall to *Dieteticæ*, or Diet, because by the use of such things it endeavours to retain and keep health: but *Therapeutice*, or the part which cures the Diseases, and all the affects besides nature, challenges the contemplation of those things which are not agreeable to nature. But the things which are called Naturall, may be reduced to seven heads: besides which there comes into their fellowship, those which we term annexed.

From whence we must draw Indications.

What things are called naturall.

To what part of physick things not naturall pertain. To what things besides nature:

CHAP. IIIII.

Of Elements.

AN Element (by the definition which is commonly received amongst Physicians) is the least and most simple portion of that thing which it composeth: or that my speech may be the more plain: the four first and simple bodies are called Elements; Fire, Air, Water, and Earth; which accommodate and subject themselves as matter to the promiscuous generation of all things which the Heavens engirt, whether you understand things perfectly, or unperfectly mixed. Such Elements are only to be conceived in your mind, being it is not granted to any externall sense to handle them in their pure and absolute nature. Which was the cause that *Hippocrates* expressed them not by the names of substances; but of proper qualities, saying, Hot, Cold, Moist, Dry; because some one of these qualities is inherent in every Element, as his proper and essential form, not only according to the excess of latitude, but also of the active faculty; to which is adjoined another simple quality, and by that reason principall, but which notwithstanding attains not to the highest degree of his kind, as you may understand by *Galen* in his first book of Elements. So, for example sake, in the Air we observe two qualities, Heat and Moisture, both principall, and not remitted by the commixture of any contrary quality, for otherwise they were not simple. Therefore thou maist say, What hinders that the principall effects of heat shew not themselves as well in the Air, as in the Fire? because, as we said before, although the Air have as great a heat according to his nature, extent, and degree, no otherwise than Fire hath, yet it is not so great in its active quality. The reason is, because that the calcfactory force in the Air is hindered, and dulled by society of his companion and adjoynd quality, that is, Humidity which abateth the force of heat, as on the contrary, driness quickneth it. The Elements therefore are endewed with these qualities.

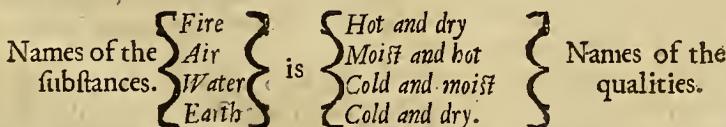

What an Element is.

Elements are understood by reason, nor by sense.

Why *Hipp.* expressed the Elements by these names of qualities.

Two principal qualities are in each Element.

Why the Air heats not so vehemently, as the Fire.

These four Elements in the composition of naturall bodies, retain the qualities they formerly had, but that by their mixture and meeting together of contraries, they are somewhat tempered and abated. But the Elements are so mutually mixed one with another, and all with all, that no simple part may be found; no more than in a mass of the Emplaster *Diacaltheos* you can shew any *Axungia* oil, or *Litharge* by it self; all things are so confused

How the Elements may be understood to be mixed in compound bodies.

Why of the first qualities, two are active, and two passive.

Why the first qualities are so called.

What the second qualities are.

What Elements light, what heavy.

What the Elements of generation are.

What the Elements of mixt bodies.

and united by the power of heat, mixing the smallest particulars with the smallest, and the whole with the whole, in all parts. You may know and perceive this concretion of the four Elementary substances in one compound body, by the power of mixture, in their dissolution by burning a pile or heap of green wood: For the flame expresses the Fire; the smoke, the Air; the moisture that sweats out at the ends, the Water; and the ashes, the Earth: You may easily perceive by this example so familiar and obvious to the senses, what dissolution is, which is succeeded by the decay of the compound body; on the contrary, you may know that the coagmentation, or uniting and joyning into one of the first mixed bodies is such, that there is no part sincere or without mixture. For if the heat which is predominant in the fire, should remain in the mixture in its perfect vigor, it would consume the rest by its pernicious neighborhood; the like may be said of Coldness, Moisture, and Driness; although of these qualities, two have the title of Active, that is, Heat and Coldness, because they are the more powerfull; the other two Passive, because they may seem more dull and slow, being compared to the former. The temperaments of all sublunary bodies arise from the commixture of these substances and elementary qualities, which hath been the principall cause that moved me to treat of the Elements. But I leave the force and effects of the Elementary qualities to some higher contemplation, content to have noted this, that of these first qualities, (so called, because they are primarily and naturally in the four first bodies) others arise and proceed, which are therefore called the second qualities: as of many, these, Heaviness, Lightness, variously distributed by the four Elements, as the Heat or Coldness, Moistness or Driness have more power over them. For of the Elements, two are called light, because they naturally affect to move upwards: the other two heavie, by reason they are carryed downward by their own weight. So we think the fire the lightest, because it holds the highest place of this lower world; the Air, which is next to it in site, we account light; for the water which lies next to the Air, we judg heavie; and the earth the center of the rest we judg to be the heaviest of them all. Hereupon it is, that light bodies, and the light parts in bodies, have most of the lighter Elements; as on the contrary heavie bodies have more of the heavier. This is a brief description of the Elements of this frail world, which are only to be discerned by the understanding, to which I think good to adjoin another description of other Elements, as it were arising or flowing from the commixture of the first: For besides these, there are said to be Elements of generation, and Elements of mans body. Which as they are more corporall, so also are they more manifest to the sense. By which reason *Hippocrates* being moved, in his Book *de Natura humana*, after he had described the nature of Hot, Cold, Moist, and Dry, he comes to take notice of these by the order of composition. Wherefore the Elements of our generation, as also of all creatures which have blood, are seed and menstruous blood. But the Elements of our bodies, are the solid and similar parts arising from those Elements of generation. Of this kind are bones, membranes, ligaments, veins, arteries, and many others manifest to the eyes, which we will describe at large in our Treatise of Anatomie.

CHAP. V.

Of Temperaments.

What a Temperament is;

+ *Anima*.
What the life performs in Plants.

* *Anima*.
What in beasts. Mans soule comes from above.

The manifold division of a Temperament.

A Temperament, *ad Pendum*.

Temperament is defined, a proportionable mixture of hot, cold, moist, and dry; or, it is a concord of the first disagreeing faculties. That harmony springs from the mixture of the four first bodies of the world. This whether Temperament or Concord is given to Plants and brute Beasts for the beginning of their life, and so consequently for their life and form. But as Plants are inferior in order and dignity to beasts, so their * life is more base and infirm, for they have only a growing faculty, by which they may draw an Alimentary juice from the earth, as from their mothers breasts, to preserve them and their life, by which they may grow to a certain bigness; and lastly, by which they may bring forth their like for the perpetuall continuance of their kind. But the * life of beasts, have to the three former, the gift of sense annexed: by benefit whereof, as by a certain inward knowledg they shun those things that are hurtfull, and follow those which profit them; and by the power of their will, they move themselves whither they please. But the soul of man far more perfect and noble than the rest, ariseth not from that earthly mixture and temper of the Elements, but acknowledgeth and hath a far more divine off-spring; as we shall teach hereafter.

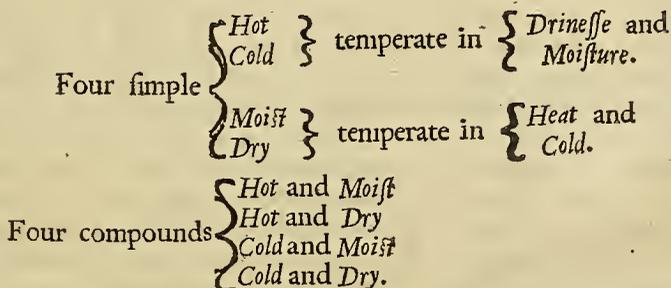

They divide a Temperament at the first division, into two kinds; as one a temperate, another an untemperate. The untemperate is of two sorts: The one wholly vicious, which hath altogether exceeded the bounds of mediocrity: The other, which hath somewhat strayed from the mediocrity of temper, but notwithstanding is yet contained within the limits of health: as that which brings no such evident harm to the actions, but that it somewhat hinders them, so that they cannot so well and perfectly perform their duties. But the vicious Temperament doth three manner of wayes corrupt the functions, either by weak-

weakening, depraving, or abolishing them. For so stupor, or astonishment, diminisheth and sloweth the quickness of motion; convulsion depraves it; the Palsie abolisheth it, and taketh it away. The temperate Temperament is also divided into two kinds; which is either to equality of weight or justice. It is called a Temperature to weight which ariseth from the equall force of exactly concurring qualities, and as placed in a perfect balance, draws down neither to this nor that part. They think the example of this Temperament: to appear in the inner skin of the fingers ends of a man tempered to Justice. For seeing the most exquisite touch resides there, they ought to be free from all excess of contrariety; for otherwise being corrupted by too much heat or cold, moisture or driness; they could give no certain judgment of the tangible qualities. For which thing nature hath excellently provided in the fabrick and coagmentation of the parts, of which the skin consists. For it is composed of hot and moist flesh, and therefore soft, and of a tendon and nerve cold and dry, and therefore hard; which are not only equally fitted and conjoynd, but wholly confused and mixed together, by which it comes, that removed from all extremes of opposition, it is placed in the midst, as a rule to judg of all the excesses that happen to the touch. So it was fit the eye, which was to be the instrument of sight; should be tintured with no certain colour, that it might be the less deceived in the judgment of colours. So it was convenient the hearing should not be troubled with any distinct sound, whereby it might more certainly judg of equall and unequal sounds, not distinguished by a ratable proportion; neither was it fit the tongue should have any certain taste, lest the access of that taste should deceive it in knowing and judging of so many different tastes. The Temperature tempered to justice, is that, which although it is a little absent from the exact and severe parity of mixed qualities, yet hath that equality which doth fully and abundantly suffice for to perform all the functions fitly and perfectly, which nature doth require, wherefore we can judg no otherwise of it than by the integrity of the Actions. For hence it took its name; for as distributive Justice equally gives to every one rewards, or punishment according to their deserts; so Nature, having regard to all the parts of the body, gives them all that temper which may suffice to perform those duties, for which they are ordained. Let us for an example consider a Bone; no man doubts, but that, like as the other similar parts of the body, proceeds from the mixture of the four Elements: but nevertheless nature weighing the use of it, and ordaining it to support the rest of the body, would have more of the terrene and dry Element infused into it, that it might be the stronger and firmer to sustain weight. But a Ligament, seeing it was made for other uses, hath less of that earthly driness than the bone, but more than the flesh, altogether fitted to its nature. So it hath seemed good to nature to endue all the parts of the body, not only with an equall portion, but also proportion of Elements and qualities; we call that a Temperament to justice: and we say, that it is in Plants, brute Beasts, and all naturall bodies, which enjoy that temper and mediocrity, which may be agreeable to their nature. Hereupon by comparison arise eight kinds of intemperate tempers: As

Ad pondus, vel ad justitiam.

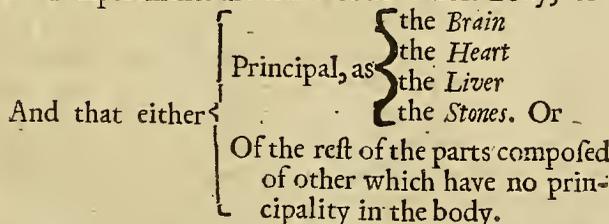

A Temperament *ad justitiam.*

The temperament of a bone.

The kinds of intemperate tempers.

But these Temperaments are either of the whole Body, or of some part thereof;

Again, such Temperaments are either healthfull, which suffice perfectly to perform their actions; or unhealthfull, which manifestly hurt them, the signes whereof may be read described by *Galen*. And you must observe that when we say the body, or any part of it is hot, we understand more hot than is fit for one of that kinde which is tempered to justice; as when we say a man hath a hot liver, we mean his liver is hotter, than a man justly tempered should have; for all other tempers, whether of the whole body, or any of the parts thereof, are to be referred to this; and in the cure of diseases we must look upon it, as the mark, and labour to preserve it by the use of convenient things, as much as lies in our power. Wherefore, because it is very necessary to know the distinction of Temperaments, I have

Lib. 2. de Tem: per. & in Arte medica.

What the temperaments of mans body are.

thought good in this place, briefly to handle the Temperaments of the parts of the body, ages, seasons of the year, humors, and medicines. Therefore the temperaments of the parts of our body are of this nature, not only by the judgment of the touch of a mans hand, which is justly tempered, (who is often deceived by flowing heat, which spread from the heart into all the body, imparts a certain kind of heat to all the parts) but also by the rule of their reason, composition and substance, as

A Bone is the most dry and cold.

A Gristle less than it.

A Ligament less than a Gristle.

A Tendon is so much dryer and colder than the membrane, by how much

it in the same temper exceeds a Vein and Artery. Then follow the harder Veins, for the softer are in a middle temper of dryness and moisture, like as the skin; although all, both soft and hard, are of a cold temper. Wherefore all these parts of their own nature are cold and without blood: although the Veins and Arteries wax hot, by reason of the heat of the blood they contain, which notwithstanding also borroweth that heat from the heart, as a part most hot, and softer than the skin; the liver next followeth the heart, in the order of the hotter parts, which is far softer than the skin it self: for if, according to Galens opinion, the heart is somewhat less hard than the skin, and that is far harder than the liver, as appears by touching them, it must necessarily follow that the liver much exceeds the skin in softness; I understand the skin simple, and separated from the flesh lying under it, to which it firmly cleaves. The flesh is more moist and hot than the skin, by reason of the blood dispersed in it. The spinall marrow is colder and moister than the skin; but the brain so much exceeds it in moisture, as it is exceeded by the fat. The lungs are not so moist as the fat; and the spleen, and kidneys are of the like nature, and nevertheless they are all moister than the skin.

Ad finem, lib. de temper.

The temperaments of ages.

According to the diversities of ages, the temperaments both of the whole body, and all its parts, undergo great mutations; for the bones are far harder in old men than in children, because our life is, as it were, a certain progress to dryness; which when it comes to the height, consequently causeth death. Wherefore in this place we must speak of the Temperaments of ages, when first we shall have defined what an age is. Therefore an age is defined, A space of life in which the constitution of the body of its self and own accord, undergoeth manifest changes. The whole course of life hath four such Ages. The first is Childhood, which extends from the birth to the eighteenth year of age, and hath a hot and moist temper, because it is next to the hot and moist beginnings of life, seed, and blood. Youth followeth this, which is prolonged from the eighteenth to the twenty fifth year, and is temperate, and in the midst of all excesses. Mans estate succeedeth youth, which they deny to extend beyond the thirty fifth year of age, in its proper temper it is hot and dry; whereby it cometh to pass that then the heat is felt more acrid and biting, which in childhood seemed milde; because the progress of the life to dryness, hath much wasted the native humidity.

What an age is.

Old-age divided into two parts.

* Three degrees of the second part of Old-age.

Then succeeds Old-age, ever divided into two parts; the first whereof extends from the thirty fifth, to the forty ninth year; those of this age are called Old-men, (*but we commonly call them middle-aged men.) The latter is, as it were, divided by Galen into three degrees; the first whereof are those, who having their strength sound and firm, undergo civil affairs and businesses: which things those which are in the second degree of Old-age cannot do, because of the debility of their now decaying strength: but those which are in the last degree, are afflicted with most extreme weakness and misery, and are as much deprived of their senses and understanding, as of the strength of their bodies; whereof arose this Proverb, *Old men, twice children.* Those Old men of the first rank are pleasant and courteous; and those we say, are beginning to grow Old, or in their green Old-age; those of the second sort delight in nothing but the board and bed; but old decrepit men of the last order, think of nothing else, than their graves and monuments. Their firm and solid parts are of a cold and dry temperature, by reason of the decay of the radical moisture, which the inbred heat causeth in the continuance of so many years. Which thing may happen in a short space, by the vehement flame of the same naturall heat, turned by fevers into a fiery heat. But if any to prove Old men moist, will object, That they cough up, and spit much, I will answer him, as an old Doctor once said; That a pitcher filled with water, may pour forth much moisture; yet no man will deny but that such a vessel of its own terrene nature and matter is most dry; so old men may plainly be affirmed to be moist, by reason of their defect of heat, and abundance of excrements. But this description of ages is not to be taken so strictly as always to be measured by the spaces and distances of years, for there are many which by their own misdemeanor seem elder at forty, than others do at fifty.

Old men have their solid parts dry.

A comparison of the four ages to the four seasons of the year

Lastly, the famous Philosopher *Pythagoras* divided mans life into four ages, and by a certain proportion compared the whole course thereof to the four seasons of the year; as Childhood to the Spring, in which all things grow and sprout out, by reason of plenty and abundance of moisture. And Youth to the Summer, because of the vigor and strength which men enjoy at that age. And mans estate, or constant age, to Autumn; for that then

after

after all the dangers of the fore-passed life, the gifts of discretion and wit acquire a seasonableness or ripeness, like as the fruits of the earth enjoy at that season. And lastly, he compares Old-age to the sterile and fruitless Winter, which can ease and console its tediousness by no other means, than the use of fruits gathered and stored up before, which then are of a cold and troublesome condition. But for extreme Old-age, which extends to eighty or a hundred years, it is so cold and dry, that those which arrive at that decrepit age are troublesome, harsh, touchy, froward, crabby, and often complaining, untill at the length deprived of all their senses, tongue, feet, and understanding, they doting, return again to childishness, as from the staff to the start. And thus much of the Temperaments of ages.

But now in like manner we will explain the Temperatures of the seasons of the year, which are four; the Spring, Summer, Autumn, Winter. The Spring continues almost from the twelfth or thirteenth day of March to the midst of May; Hippocrates seemeth to make it hot and moist; which opinion seemeth not to have sprung from the thing it self, but from an inveterate error of the ancient Philosophers, who would fit the Temperaments of the four seasons of the year, as answering in proportion to the temperatures of the four ages. For if the matter come to a just tryall, all men will say, the Spring is temperate, as that which is in the midst of the excess of heat, cold, moisture and driness; not only by comparison, because it is hotter than Summer, and colder than Winter; but because it hath that quality of its own proper nature. Wherefore it is said of Hippocrates, The Spring is most wholesome, and least deadly; if so be that it keep its native temper, from which if it decline, or succeed a former untemperate season, as Autumn or Winter, it will give occasion to many diseases described by Hippocrates; not that it breeds them, but because it brings them to fight, which before lay hid in the body. Summer is comprehended in the space of almost four months; it is of a hot and dry temper, a breeder of such diseases as proceed from choler, because that humor at this time is heaped up in many bodies by aduision of blood bred in the Spring; but all such diseases do speedily run their course. The beginning of Autumn, is from the time the Sun enters into Libra, and endures the like space of time as the Spring. But when it is dry, it hath great inequality of heat and cold, for the mornings and evenings being very cold, the noondays on the contrary are exceeding hot. Wherefore many diseases are in Autumn, and then long and deadly, especially if they incline towards Winter; because all daily and sodain changes to heat and cold are dangerous. The Winter possesses the remnant of the year, and is cold and moist, it increases naturall heat, stirs up the appetite, and augments Phlegme. It encreases heat by *Antiperistasis*; or contrariety of the encompassing air, which being then cold, prohibits the breathing out of heat: whereby it happens that the heat being driven in and hindered from dissipation, is strengthened by co-uniting its forces. But it augments Phlegme, for that men are more greedy, the Appetite being encreased by the strengthened heat: from whence proceeds much crudity, and a large store of diseases, especially Chronick or Long, which spread and encrease rather in this winter-season than in any other part of the year. To this discourse of the temper of the seasons of the years, is to be revoked the variety of tempers which happens every day, which certainly is not to be neglected, that there may be place of election, especially if nothing urge. For hither belongs that saying of Hippocrates; When in the same day it is one while hot, another cold, Autumnall diseases are to be expected. Therefore an Indication taken from hence is of great consequence to the judgment of diseases; for if it agree with the disease, the disease is made more contumacious, and difficult to cure. Whereupon the Patient and Physitian will have much trouble; but if on the contrary it reclaim and dissent, the health of the Patient is sooner to be expected. Neither is it a thing of less consequence to know the customs and habits of the places and Countreys in which we live; as also the inclination of the Heavens, and temperature of the Air; but let us leave these things to be considered by Naturall Philosophers, that we may deliver our judgment of the temperaments of *Humors*. Blood, as that which answers to the Air in proportion, is of a hot and moist nature, or rather temperate, as Galen testifies; for, saith he, it is certain and sure, that the Blood is neither hot nor moist, but temperate, as in its first composition none of the four first Qualities exceeds other by any manifest excess, as he repeats it upon the 39th Sentence. Phlegm, as that which is of a waterish nature, is cold and moist; no otherwise than Choler being of a fiery temper, is hot and dry. But Melancholy assimilated to earth, is cold and dry. This which we have spoken in generall of Phlegm and Melancholy, is not always true in every kind of the said Humors. For salt Phlegm is of a hot and dry temperature; as also all kinds of Melancholy which have arose or sprung by aduision from the native and alimentary, as we will teach in the following Chapter. Now the temperaments of Medicines have not the same form of judgment, as those things which we have before spoken of; as, not from the Elementary quality, which conquering in the contention and mixture, obtains the dominion; but plainly from the effects, which taken or applied, they imprint in a temperate body. For so we pronounce those things, hot, cold, moist, or dry, which produce the effects of Heat, Coldness, Moisture, or Dryness. But we will defer the larger explication of these things to that place, where we have peculiarly appointed

appointed to treat of Medicines; where we will not simply enquire whether they be hot or cold, but what degree of heat and cold, or the like other quality: in which same place we will touch the temperature and all the nature of tastes, because the certainest judgment of Medicines is drawn from their tastes. Hitherto of Temperaments; now we must speak of Humors, whose use in Physicall speculation is no less than that of Temperaments.

C H A P. VI.

Of Humors.

The knowledge
of the Humor
is necessary.
Lib. De natura
Humana.

To know the nature of *Humors*, is a thing not only necessary for Physitians, but also for Chirurgions, because there is no disease with matter which ariseth not from some one, or the mixture of more *Humors*. Which thing *Hippocrates* understanding, writ, every Creature to be either sick or well according to the condition of the *Humors* in the body. And certainly all putrid feavers proceed from the putrefaction of *Humors*. Neither do any acknowledg any other originall or distinction of the differences of Abscesses or Tumors: neither do ulcerated, broken, or otherwise wounded members hope for the restauration of continuity, from other than from the sweet falling down of *Humors* to the wounded part. Which is the cause that often in the cure of these affects, the Physitians are necessarily busied in tempering the Blood, that is, bringing to a mediocrity the four *Humors* composing the mass of blood, if they at any time offend in quantity, or quality. For whether if any thing abound or digress from the wonted temper in any excess of heat, cold, viscosity, grossness, thinness, or any such like quality, none of the accustomed functions will be well performed. For which cause those chief helps to preserve and restore health have been divinely invented: *Phlebotomie*, or blood-letting, which amends the quantity of too much blood; and *Purging*, which corrects and draws away the vicious quality. But now let us begin to speak of the *Humors*, taking our beginning from the definition.

The helps of
Health.

of Cholera and
Melancholy.

Four unlike
Humors in the
Blood.

An Humor (is called by Physitians) what thing so ever is liquid and flowing in the body of living Creatures endued with Blood; and that is either naturall, or against nature. The naturall is so called because it is fit to defend, preserve and sustain the life of a Creature. Quite different is the nature and reason of that which is against nature. Again, the former is either Alimentary or Excrementitious: The Alimentary which is fit to nourish the body, is that Humor which is contained in the veins and arteries of a man which is temperate and perfectly well; and which is understood by the generall name of Blood, which is let out at the opening of a vein. For Blood otherwise taken, is an Humor of a certain kind, distinguished by heat and warmness from the other *Humors* comprehended together with it, in the whole mass of the blood. Which thing, that it may the better be understood, I have thought good in this place to declare the generation of Blood by the efficient and materiall causes. All things which we eat or drink, are the materials of Blood; which things drawn into the bottom of the Ventricle by its attractive force, and there detained, are turned by the force of concoction implanted in it, into a substance like to Almond-butter. Which thing, although it appear one and like it self, yet it consists of parts of a different nature, which not only the variety of meats, but one and the same meats yeelds of it self. We term this *Chylus*, (when it is perfectly concocted in the stomach.) But the* Gate-vein receives it driven from thence into the small Guts, and sucked in by the Meseraick-veins, and now having gotten a little rudiment of change in the way, carries it to the Liver, where by the Blood-making faculty, which is proper and naturall to this part, it acquires the absolute and perfect form of Blood. But with that Blood, at one and the same time and action all the *Humors* are made, whether alimentary or excrementitious. Therefore the Blood, that it may perform its office, that is, the faculty of nutrition, must necessarily be purged and cleansed from the two excrementitious *Humors*: of which the bladder of Gall draws one, which we call yellow Cholera; and the Spleen the other, which we term Melancholy. These two *Humors* are naturall, but not alimentary or nourishing, but of another use in the body, as afterwards we will shew more at large. The Blood freed from these two kinds of Excrements, is sent by the veins and arteries into all parts of the body for their nourishment. Which although then it seem to be of one simple nature, yet notwithstanding it is truly such, that four different and unlike substances may be observed in it, as, Blood, properly so named, Phlegm, Cholera, and Melancholy, not only distinct in colour, but also in taste, effects, and qualities. For, as *Galen* notes in his book *de Natura humana*, Melancholy is acide or sour, Cholera bitter, Blood sweet, Phlegm unsavory. But you may know the variety of their effects, both by the different temper of the nourished parts, as also by the various condition of the diseases springing from thence. For therefore such substances ought to be tempered and mixed amongst themselves in a certain proportion, which remaining, health remains; but violated, diseases follow. For all acknowledg, that an *Oedema* is caused by Phlegmatick; a *Scirbus*, by Melancholick; an *Erysipelas*, by Choleric; and a *Phlegmone*, by pure

pure and laudable blood. *Galen* teaches by a familiar example of new wine presently taken from the *Præs*, that these 4 substances are contained in that one mass, and mixture of the blood. In which every one observes 4 distinct Essences; for the flower of the wine working up, swims at the top, the dregs fall down to the bottom, but the crude and watery moisture, mixed together with the sweet and vinous liquor, is every where diffused through the body of the wine: the flower of the wine, represents *Choler*, which bubbling up on the superficies of blood, as it concretes and grows cold, shineth with a golden colour; the dregs, *Melancholy*, which by reason of its heaviness ever sinketh downward, as it were, the mud of the blood; the crude and watery portion, *Phlegm*; for as that crude humor, except it be rebellious in quantity, or stubborn by its quality, there is hope it may be changed into wine, by the naturall heat of the wine; so *Phlegm*, which is blood half concocted, may by the force of native heat be changed into good and laudable blood. Which is the cause that nature decreed or ordained no peculiar place as to the other 2 Humors, whereby it might be severed from the blood: But the true and perfect liquor of the wine represents the pure blood, which is the more laudable and perfect portion of both the humors of the confused mass. It may easily appear by the following scheme, of what kind they all are, and also what the distinction of these four Humors may be.

A comparison of blood and new wine.

Phlegm is Blood half concocted. Why it hath no proper receptacle.

	NATURE.	CONSISTENCE.	COLOUR.	TASTE.	U S E.
Blood is	Of Nature aery, hot, and moist, or rather temperate.	Of indifferent consistence, neither too thick nor too thin.	Of Colour red, rosie, or crimson.	Of Taste sweet.	Of such use, that it chiefly serves for the nourishment of the fleshy parts, and carried by the vessels, imparts heat to the whole body.
Phlegm is	Of Nature watery, cold and moist.	Of Consistence, liquid.	Of Colour, white.	Of Taste, sweet, or rather unsavory, for we commend that water which is unsavory.	Fit to nourish the brain, and all the other cold and moist parts, to temper the heat of the blood, and by its slipperiness to help the motion of the joynts.
Choler is	Of Nature fiery, hot and dry.	Of Consistence, thin.	Of Colour yellow, or pale.	Of Taste, bitter.	It provoketh the expulsive faculty of the guts, attenuates the Phlegm cleaving to them, but the Alimentary is fit to nourish the parts of like temper with it.
Melancholy is	Of Nature earthy, cold, and dry.	Of Consistence, grosse and muddy.	Of Colour, blackish.	Of Taste, acide, sour or biting.	Stirs up the Appetite, nourishes the Spleen, and all the parts of like temper to it, as the bones.

Blood hath its nearest matter from the better portion of the *Chylus*: and being begun to be laboured in the veins, at length gets form and perfection in the Liver; but it hath its remote matter from meats of good digestion and quality, seasonably eaten after moderate exercise; but for that, one age is better than another, and one time of the year more convenient than another. For blood is made more copiously in the Spring, because that season of the year comes nearest to the temper of the blood, by reason of which the blood is rather to be thought temperate, than hot and moist; for that *Galen* makes the Spring temperate; and besides, at that time blood-letting is performed with the best success: Youth is an age very fit for the generation of blood; or by *Galen's* opinion, rather that part of life that continues from the 25, to the 35 year of our age. Those in whom this Humor hath the dominion, are beautified with a fresh and rosie colour, gentle, and well-natured, pleasant, merry, and facetious. The generation of *Phlegm*, is not by the imbecillity of heat, as some of the Ancients thought; who were perswaded that *Choler* was caused by a raging, *Blood* by a moderate, and *Phlegm* and *Melancholy* by a remiss heat. But that opinion is full of manifest error: for if it be true that the *Chylus* is laboured and made into blood in the same part, and by the same fire, that is, the Liver; from whence in the same moment of time should proceed that strong and weak heat, seeing the whole mass of the blood different in its four essential parts, is perfected and made at the same time, and by the same equall temper of the same part, action, and blood-making faculty; therefore from whence

Lib. 1. de temp.

One and the same heat is the efficient cause of all humors at the same time.

have

have we this variety of Humors? From hence, for that those meats by which we are nourished, enjoy the like condition that our bodies do, from the four Elements, and the four first Qualities: for it is certain, and we may often observe, in what kind soever they be united or joined together, they retain a certain hot portion imitating the fire; another cold, the water; another dry, the earth; and lastly, another moist like to the air. Neither can you name any kind of nourishment, how cold soever it be, not Lettuce it self, in which there is not some fiery force of heat. Therefore it is no marvel, if one and the same heat working upon the same matter of *Chylus*, varying with so great dissimilitude of substances, do by its power produce so unlike humors, as from the hot, Cholera; from the cold, Phlegm; and of the others, such as their affinity of temper will permit.

The heat of the Sun alone doth melt wax and harden clay.

There is no cause that any one should think that variety of humors to be caused in us, rather by the diversity of the active heat, than wax and a flint plac'd at the same time, and in the same situation of climat and soil, this to melt by the heat of the Sun, and that scarce to wax warm. Therefore that diversity of effects is not to be attributed to the force of the efficient cause, that is of heat, which is one, and of one kinde in all of us; but rather to the materiall cause, seeing it is compos'd of the conflux, or meeting together of various substances, gives the heat leave to work, as it were out of its store, which may make and produce from the hotter part therof Cholera, and of the colder and more rebellious Phlegm. Yet I will not deny, but that more Phlegm, or Cholera may be bred in one and the same body, according to the quicker, or slower provocation of the heat; yet nevertheless it is not consequent, that the originall of Cholera should be from a more acide, and of Phlegm from a more dull heat in the same man. Every one of us naturally have a simple heat, and of one kind, which is the worker of divers operations, not of it self, seeing it is always the same, and like it self, but by the different fitness, pliability, or resistance of the matter on which it works. Wherefore Phlegm is generated in the same moment of time, in the fire of the same part, by the efficiency of the same heat, with the rest of the blood, of the more cold, liquid, crude, and watery portion of the *Chylus*. Whereby it comes to pass, that it shews an express figure of a certain rude or unperfect blood, for which occasion nature hath made it no peculiar receptacle, but would have it to run friendly with the blood in the same passages of the veins, that any necessity hapning by famine, or indigency, and in defect of better nourishment, it may by a perfecter elaboration quickly assume the form of blood. Cold and rude nourishment make this humor to abound principally in winter, & in those which incline to old-age, by reason of the similitude which Phlegm hath with that season and age. It makes a man drowsie, dull, fat, and swollen up, and hastneth gray-hairs. Cholera is as it were, a certain heat and fury of humors, which generated in the Liver, together with the blood is carried by the veins and arteries through the whole body. That of it which abounds, is sent, partly into the guts, and partly into the bladder of the gall, or is consumed by transpiration, or sweats; It is somewhat probable that the Arteriall blood is made more thin, hot, quick, and pallid, than the blood of the Veins, by the commixture of this Alimentary Cholera. This Humor is chiefly bred and expel'd in youth, and acrid and bitter meats give matter to it: but great labours of body and mind give the occasion. It maketh a man nimble, quick, ready for all performance, lean, and quick to anger, and also to concoct meats. The melancholick humor, or Melancholy, being the grosser portion of the blood, is partly sent from the Liver to the Spleen to nourish it, and partly carried by the vessels into the rest of the body, and spent in the nourishment of the parts endued with an earthly driness; it is made of meats of gross juice, and by the perturbations of the mind, turned to fear and sadness. It is augmented in Autumn, and in the first and crude Old-age; it makes men sad, harsh, constant, froward, envious and fearfull. All men ought to think, that such Humors are wont to move at set hours of the day, as by a certain peculiar motion or tide, Therefore the blood flows from the ninth hour of the night, to the third hour of the day; then Cholera to the ninth of the day; then Melancholy to the third of the night; the rest of the night that remains, is under the dominion of Phlegm. Manifest examples hereof appears in the French-Pox. From the elaborat and absolute mass of the blood, (as we said before) two kinds of Humors, as excrements of the second concoction, are commonly and naturally separated, the one more gross, the other more thin. This is called either absolutely Cholera, or with an adjunct, yellow Cholera. That is called Melancholy, which drawn by the Spleen in a thinner portion, and elaborate by the heat of the Arteries, which in that part are both many and large, becomes nourishment to the part; the remnant thereof is carried by the veiny Vessel into the orifice of the ventricle, whereby it may not cause but whet the appetite, and by its astringent strengthen the actions thereof. But yellow Cholera drawn into the bladder of the gall, remains there so long, till being troublesome, either in quantity or quality, it is excluded into the guts, whereby it may cast forth the excrements residing in them; the expulsive faculty being provok'd by its acrimony, and by its bitterness kills the worms that are bred there. This same Humor is accustomed to die the urine of a yellow colour. There is another serous Humor, which truly is not fit to nourish but profitable for many other things, which is not an excrement of the second, but of the first concoction. Therefore nature would that mixed with the *Chylus*, it should come to the

The divers condition of the matter alone, is the cause of variety.

The effects of Melancholy.

What motions are in each quarter of the body.

The Melancholy Humor doth not cause, but whet the appetite.

A serous or wheyish humor

the Liver, and not be voided with the excrements, whereby it might allay the grossness of the blood, and serve it for a vehicle; for otherwise the blood could scarce pass through the capillary veins of the Liver, and passing the sinuous and gibbous parts thereof, come to the hollow vein. Part of this serous humor separated together with the blood which serves for the nourishment of the Reins, and straight carried into the bladder, is turned into that urine which we daily make; the other part therefore carryed through all the body together with the blood, performing the like duty of transportation, is excluded by sweats into which it degenerates. Besides the forenamed, the *Arabians* have mentioned four other humors, which they term Alimentary and secondary, as being the next matter of nourishment, as those four the blood contains, the remote. They have given no name to the first kind, but imagin it to be that humor, which hangs ready to fall like to little drops in the utmost orifices of the veins. They call the second kind, *Dew; being that humor, which entered already into the substance of the part, doth moisten it. The third they call by a barbarous name, *Cambium*, which already put to the part to be nourished, is there fastned. The fourth named *Gluten*, or *Glew*, is only the proper and substance-making humidity of the similar parts, not their substance. The distinction of the degrees of nutrition recited by *Galen* in his books of *Naturall faculties*, answer in proportion to this distinction of humors. The first is, that the blood flow to the part that requires nourishment; then that being there arrived, it may be agglutinated; then lastly, that having lost its former form of nourishment, it may be assimilated.

Secondary Humors.

* Ros.

Those humors are against nature, which being corrupted, infect the body and the parts in which they are contained by the contagion of their corruption, retaining the names and titles of the humors, from whose perfection and nature they have revolted, they all grow hot by putrefaction, although they were formerly by their own nature cold. And they are corrupted, either in the veins only, or within and without the veins: In the veins Blood and Melancholy; but both without and within the veins, Choler and Phlegm. When Blood is corrupted in its thinner portion, it turns into Choler, when in its thicker, into Melancholy; for the Blood becomes faulty two manner of ways, either by the corruption of its proper substance by putrefaction, or by admixtion of another substance by infection. The Melancholy humor which is corrupted in the veins, is of three sorts: The first is of a Melancholy juice putrefying, and by the force of a strange heat, turned, as it were, into ashes, by which it becomes adust, acrid and biting. The other ariseth from that Choler which resembles the yolks of eggs, which by adustion becomes leek-coloured, then æruginous, or of a blewish green, then red, and lastly black, which is the very worst kind of Melancholy, hot, malign, eating, and exulcerating, and which is never seen or voided with safety. The third comes from Phlegm putrefying in the veins, which first degenerates into salt Phlegm, but straight by the strength of extraneous heat degenerates into Melancholy.

Humors against nature.

Into what Humors the blood when it corrupts, doth degenerate. The Melancholy Humor corrupted, is of three kinds,

<p>Phlegm not naturall is bred, either</p>	<p>In the Veins, and is either</p>	<p>Acide and very crude, as which hath had none or very little impresson of heat, but that which it first had in the stomach.</p>	<p>Salt, which is bred by the sweet, putrefying and adust, or mixture of adust and salt particles.</p>		
				<p>Or without the Veins, & is of four sorts; either</p>	<p>Waterish, as is that thin moisture which distils from the brain by the nostrils.</p>
<p>Choler not naturall is bred, either</p>	<p>In the Veins, as the * vitelline (like in consistence to the yolk of a raw egg) which the acrimony of strange heat breeds of yellow Choler, which same in diseases altogether deadly, degenerates into green, æruginous, & lastly into a blue, or colourlike that which is dried by woad.</p>	<p>The first is called <i>Porracea</i>, or leek-coloured, resembling the juice of a leek in greenness.</p>	<p>The second <i>æruginosa</i>, or æruginous, like in colour to verdigrease.</p>		
				<p>Or in the capacity of the upper belly, as the ventricle, and this is of five kinds:</p>	<p>The fifth very red, generated by the excess of the former, which causeth burning feavers.</p>

* Albuminea.

* Vitellina.

The kinds of such Cholera, are often cast forth by vomit in diseases, the strength of the disease being past; being troublesome to the parts through which they are evacuated, by their bitterness, acrimony, and biting.

The signes of a Sanguine person.

I Think it manifest, because the matter and generation of flesh is principally from blood, that a man of a fleshy, dense, and solid habit of body, and full of a sweet and vaporous juice, is of a Sanguine complexion. And the same party hath a flourishing and rosy colour in his face, tempered as with an equal mixture of white and red; of white, by reason of the skin lying utmost; of red, because of the blood spread underneath the skin: for always such as the humor is, such is the colour in the face. In manners, he is courteous, gentle, easy to be spoken to, not altogether estranged from the love of women, of a lovely countenance and smooth forehead; seldom angry, but taking all things in good part; for as the inclination of humors is, so also is the disposition of manners. But blood is thought the mildest of all humors; but the strong heat of the inward parts maketh him to eat and drink freely. Their dreams are pleasant, they are troubled with diseases arising from blood, as frequent Phlegmons, and many sanguine pustles breaking through the skin, much bleeding, and menstruous fluxes. Wherefore they can well endure blood-letting, and delight in the moderate use of cold and dry things; and lastly, are offended by hot and moist things. They have a great and strong Pulse, and much urine in quantity, but milde of quality, of an indifferent colour add substance.

Such as the humor is, such is the colour.

The manners and diseases of Sanguine persons.

The signes of a Choleric person.

Choleric men are of a pale or yellowish colour, of a lean, slender and rough habit of body, with fair veins and large Arteries, and a strong and quick pulse: their skin being touched, feels hot, dry, hard, rough and harsh, with a pricking and acrid exhalation which breathes forth of their whole body. They cast forth much cholera by stool, vomit and urine. They are of a quick and nimble wit, stout, hardy and sharp vindicators of received injuries, liberall even to prodigality, and somewhat too desirous of glory. Their sleep is light, and from which they are quickly waked; their dreams are fiery, burning, quick, and full of fury; they are delighted with meats and drinks which are somewhat more cold and moist, and are subject to Tertian and burning fevers, the Phrensie, Jaundise, Inflammations, and other Choleric pustles, the Lask, Bloody flux, and bitterness of the mouth.

Choleric are nor commonly fat.

The manners and diseases of Choleric persons.

The signes of a Phlegmatick person.

Those in whom Phlegm hath the dominion, are of a whitish coloured face, and sometimes livid and swollen, with their body fat, soft, and cold to touch.

They are molested with Phlegmatick diseases, as Oedematous tumors, the Dropsie, Quotidian fevers, falling away of the hairs, and catarrhes falling down upon the Lungs, and the *Astera Arteria*, or Weason: they are of a slow capacity, dull, slothfull, drowsie; they do dream of rains, snows, floods, swimming, and such like, that they often imagin themselves overwhelmed with waters; they vomit up much watery and Phlegmatick matter, or otherwise spit and evacuate it, and have a soft and moist tongue.

And they are troubled with a dog-like hunger, if at any time it should happen that their insipid Phlegm become acide; and they are slow of digestion, by reason of which they have great store of cold and Phlegmatick humors; which if they be carried down into the windings of the Colick-gut, they cause murmuring and noise, and sometimes the Colick.

For much wind is easily caused of such like Phlegmatick excrements wrought upon by a small and weak heat, such as Phlegmatick persons have, which by its naturall lightness is diversly carried through the turnings of the guts, and distends and swells them up, and whiles it strives for passage out, it causeth murmurings and noises in the belly, like wind breaking through narrow passages.

The manners and diseases of phlegmatick persons.

From whence noise or rumbling in the belly proceeds.

Signes of a Melancholick person.

The face of Melancholy persons is swart, their countenance cloudy and often cruell, their aspect is sad and froward; frequent Scirrhus, or hard swellings, tumors of the Spleen, Hemorrhoids, *Varices* (or swollen Veins) Quartain fevers, whether continuall or intermitting; Quintain, Sextain, and Septimane fevers: and to conclude, all such wandering fevers or agues set upon them. But when it happens the Melancholy humor is sharpned, either by aduption, or commixture of Cholera, then Tetters, the black Morpew, the Cancer simple and ulcerated, the Leprous and filthy scab, sending forth certain scaly and branlike excrescences, (being vulgarly called Saint *Manis* his evil;) and the Leprosie it self invades them: They have small veins and arteries, because coldness hath dominion over them; whose property is to straiten, as the quality of heat is to dilate. But if at any time their Veins seem big, that largeness is not by reason of the laudable

Diseases familiar to Melancholy persons.

laudable blood contained in them, but from much windiness; by occasion whereof it is somewhat difficult to let them blood; not only, because that when the Vein is opened, the blood flows slowly forth, by reason of the cold flowness of the humors; but much the rather, for that the vein doth not receive the impressiō of the Lancet, sliding this way and that way, by reason of the windiness contained in it, and because that the harsh driness of the upper skin, resists the edge of the instrument. Their bodies seem cold and hard to the touch, and they are troubled with terrible dreams, for they are observed to seem to see in the night Devils, Serpents, dark dens and caves, sepulchers, dead corpses, and many other such things full of horror, by reason of a black vapor, diversly moving and disturbing the brain, which also we see happens to those, who * fear the water, by reason of the biting of a mad dog. You shall finde them froward, fraudulent, parsimonious, and covetous even to baseness, slow speakers, fearfull, sad, complainers, carefull, ingenious, lovers of solitariness, man-haters, obstinate maintainers of opinions once conceived, slow to anger, but angred not to be pacified. But when Melancholy hath exceeded natures and its own bounds, then by reason of putrefaction and inflammation all things appear full of extreme fury and madness, so that they often cast themselves headlong down from some high place, or are otherwise guilty of their own death, with fear of which notwithstanding they are terrified.

From, or by what their Veins are swollen.

Their dreams.

* *Hydrophobi.*
Their manners.

But we must note that changes of the native temperament, do often happen in the course of a mans life, so that he which a while agoe was Sanguine, may now be Cholerick, Melancholick, or Phlegmatick; not truly by the changing of the blood into such Humors, but by the mutation of Diet, and the course or vocation of life. For none of a Sanguine complexion but will prove Cholerick if he eat hot and dry meats, (as all like things are cherished and preserved by the use of their like, and contraries are destroyed by their contraries) and weary his body by violent exercises, and continuall labors; and if there be a suppression of Cholerick excrements, which before did freely flow, either by nature or art. But whosoever feeds upon Meats generating gross blood, as Beef, Venison, Hare, old Cheese, and all salt meats, he without all doubt sliding from his nature, will fall into a Melancholy temper; especially if to that manner of diet, he shall have a vocation full of cares, turmoils, miseries, strong and much study, carefull thoughts and fears; and also if he sit much, wanting exercise, for so the inward heat, as it were, defrauded of its nourishment, faints, and grows dull, whereupon gross and drossie humors abound in the body. To this also the cold and dry condition of the place in which we live, doth conduce, and the suppression of the Melancholy humor accustomed to be evacuated by the Hemorrhoids, courses, and stools.

From whence the change of the native temper.

How one may become Cholerick.

How Melancholick.

But he acquires a Phlegmatick temper, whosoever useth cold and moist nourishment; much feeding, who before the former meat is gone out of the belly, shall stuff his paunch with more, who presently aftermeat runs into violent exercises, who inhabit cold and moist places; who lead their life at ease in all idleness; and lastly, who suffer a suppression of the Phlegmatick humor accustomedly evacuated by vomit, cough, or blowing the nose, or any other way, either by nature or art. Certainly it is very convenient to know these things, that we may discern if any at the present be Phlegmatick, Melancholick, or of any other temper, whether he be such by nature, or necessity. Having declared those things which concern the nature of Temperaments, and deferred the description of the parts of the body to our Anatomy, we will begin to speak of the Faculties governing this our life, when first we shall have shewn by a practicall demonstration of examples, the use and certainty of the aforesaid rules of Temperaments.

How Phlegmatick.

CHAP. VII.

Of the Practice of the aforesaid rules of Temperaments.

That we may draw the Theorick of the Temperaments into practice, it hath seemed good for avoyding of confusion which might make this our Introduction seem obscure, if we would prosecute the differences of the Tempers of all men of all Nations, to take those limits which Nature hath placed in the world; as South, North, East, and West, and, as it were, the Center of those bounds, that the described variety of Tempers, in colour, habit, manners, studies, actions, and form of life of men that inhabit those Regions situated so far distant one from another, may be as a sure rule, by which we may certainly judg of every mans temperature in particular, as he shall appear to be nearer or further off from this or that Region. Those which inhabit the South, as the *Africans*, *Aethiopians*, *Arabians*, and *Egyptians*, are for the most part deformed, lean, duskie coloured, and pale, with black eys and great lips, curled hair, and a small and shrill voice. Those which inhabit the Northern parts, as the *Scythians*, *Muscovites*, *Polonians*, and *Germanes*, have their faces of colour white, mixed with a convenient quantity of blood, their skin soft and delicate, their hair long, hanging down

Four bounds or Regions of the world.

The forces of temperatures in particulars. The temperature of the Southern people. Of the Northern.

down and spreading abroad, and of a yellowish, or reddish colour; of stature they are commonly tall, and of a well proportioned, fat and compact habit of body, their eyes gray, their voice strong, loud and big. But those who are situated between these two former, as the *Italians* and *French*, have their faces somewhat swart, are well favoured, nimble, strong, hairy, slender, well in flesh, with their eyes resembling the colour of Goats-eyes, and often hollow eyed, having a clear, shrill and pleasing voice.

The Southern people are exceeded so much by the Northern in strength and ability of body, as they surpass them in wit and faculties of the mind. Hence is it you may read in Histories, that the *Scythians*, *Goths* and *Vandals* vexed *Africk* and *Spain* with infinite incurfions, and most large and famous Empires have been founded from the North to South; but few or none from the South to the North. Therefore the Northern people thinking all right and law to consist in Arms, did by Duell only determine all causes and controversies arising amongst the Inhabitants, as we may gather by the ancient laws, and customes of the *Lumbarbs*, *English*, *Burgonians*, *Danes* and *Germans*; and we may see in *Saxo* the *Grammarian* that such a law was once made by *Frono* King of *Denmark*. The which custome at this day is every where in force amongst the *Muskovites*. But the Southern people have alwayes much abhorred that fashion, and have thought it more agreeable to Beasts than Men. Wherefore we never heard of any such thing used by the *Assyrians*, *Ægyptians*, *Persians* or *Jews*. But moved by the goodness of their wit, they erected Kingdomes and Empires by the onely help of Learning and hidden sciences. For seeing by nature they are Melancholik, by reason of the dryness of their temperature, they willingly addict themselves to solitariness and contemplation, being endued with a singular sharpness of wit. Wherefore the *Æthiopians*, *Egyptians*, *Africans*, *Jews*, *Phanicians*, *Persians*, *Assyrians*, and *Indians*, have invented many curious sciences, revealed the Mysteries and secrets of Nature, digested the *Mathematiques* into order, observed the motions of the heavens, and first brought in the worship and religious sacrifices of the gods: Even so far that the *Arabians* who live only by stealth, and have only a Waggon for their house, do boast that they have many things diligently and accurately observed in Astrology by their Ancestors, which every day made more accurate and copious, they, as by an hereditary right, commend to posterity, as it is recorded by *Leo* the *African*. But the Northern people, as the *Germans*, by reason of the abundance of humors and blood, by which the mind is as it were oppressed, apply themselves to works obvious to the senses, and which may be done by the hand. For their minds oppressed with the earthly mass of their bodies, are easily drawn from heaven and the contemplation of Celestiall things, to these inferior things, as to find out Mines by digging, to buy and cast metalls, to draw and hammer out works of Iron, steel and brass. In which things they have proved so excellent, that the glory of the Invention of Guns and Printing belongs to them.

The people who inhabit the middle regions between these, are neither naturally fit for the more abstruse sciences, as the Southern people are, nor for Mechanick works, as the Northern, but intermeddle with civil affairs, commerce and Merchandizing. But are endued with such strength of body as may suffice to avoid and delude the crafts and arts of the Southern Inhabitants; and with such wisdom as may be sufficient to restrain the fury and violence of the Northern. How true this is, any one may understand by the example of the *Carthaginians* and *Africans*, who when they had held *Italy* for some years by their subtle counsels, crafty sleights and devices; yet could not escape, but at the length their Arts being deluded, and they spoiled of all their fortunes, were brought in subjection to the *Romans*. The *Goths*, *Hunnies* and other Northern people have spoiled and overrun the *Romane* Empire by many incurfions and inroads, but destitute of counsell and providence, they could not keep those things which they had gotten by Armes and valour. Therefore the opinion of all Historians is agreeing in this, that good laws, the form of governing a Common-wealth, all politick ordinances, the Arts of disputing and speaking, have had their beginnings from the *Greeks*, *Romans* and *French*. And from hence in times past and at this day a greater number of Writers, Lawyers and Counsellors of State have sprung up, than in all the whole world besides. Therefore that we may attribute their gifts to each Region, we affirm that, The Southern people are born and fit for the Studies of learning, the Northern for warres, and those which be between them both for Empire and rule. The *Italian* is naturally wise, the *Spaniard* grave and constant; the *French* quick and diligent, for you would say hee runs when he goes, being compared to the slow and womanish pace of the *Spaniard*, which is the cause that *Spaniards* are delighted with *French* servants for their quick agility in dispatching business. The Eastern people are specially indued with a good, firm and well tempered wit, not keeping their counsels secret and hid. For the haste is of the nature of the Sun, and that part of the day which is next to the rising of the Sun is counted the right side and stronger; and verily in all things living the right side is alwayes the more strong and vigorous. But the Western people are more tender and effeminate, and more close in their carriage and mind,

not.

The Southern people prevail in wit, the Northern in strength.

The Southern people learned and religious.

The Northern famous Warriors, and Artificers.

The endowments of such as inhabit between them.

The Northern know how to overcome, but not how to use the victory.

The abundance of counsellors and Lawyers from France and Italy.

The manners of the Eastern people.

not easily making any one partaker of their secrets. For the West is as it were subject to the Moon, because at the change it alwayes inclines to the West, whereby it happens, that it is reputed as nocturnall, sinister and opposite to the East; and the West is less temperate and wholesome. Therefore of the winds none is more wholesome than the Eastwind which blows from the West with a most fresh and healthfull gale, yet it seldome blows, and but only at Sun-set.

The Northern people are good eaters, but much better drinkers, witty when they are a little moistened with wine, and talkers of things both to be spoken and concealed, not very constant in their promises and agreements, but principal keepers and preservers of shamefastness and chastity, far different from the inhabitants of the South, who are wonderfull sparing, sober, secret and subtle, and much addicted to all sorts of wicked Lust. Aristotle in his Problemes saith that those nations are barbarous and cruell, both which are burnt with immoderate heat, and which are oppressed with excessive cold, because a soft temper of the Heavens, softens the manners and the mind. Wherefore both, as well the Northern, as Scythians and Germans; and the Southern, as Africans, are cruell; but these have this of a certain naturall stoutness, and souldierlike boldness, and rather of anger than a willfull desire of revenge; because they cannot refrain by the power of reason the first violent motions of their anger by reason of the heat of their blood. But those of a certain inbred and inhumane pravity of manners, wilfully and willingly premeditating they perform the works of cruelty, because they are of a sad and melancholy nature. You may have an example of the Northern cruelty from the Transilvanians against their seditious Captain George, whom they gave to be torne in pieces alive and devoured by his Souldiers, (being kept fasting for three dayes before for that purpose) who was then unbowelled, and roasted, and so by them eaten up. The cruelty of Hannibal the Captain of the Carthaginians may suffice for an instance of the Southern cruelty. He left the Roman Captives wearied with burdens and the length of the way, with the soles of their feet cut off; But those he brought into his tents, joyning brethren and kinsmen together he caused to fight, neither was satisfied with blood before he brought all the victors to one man. Also we may see the cruell nature of the Southern Americans, who dip their children in the blood of their slain enemies, then suck their blood, and banquet with their broken and squeased Limbs.

And as the Inhabitants of the South are free from divers Plethorick diseases, which are caused by abundance of blood, to which the Northern people are subject, as Feavers, De-fluxions, Tumors, Madnes with laughter which causeth those which have it to leap and dance, (the people commonly tearm it *S. vitus his evill*) which admits of no remedy but Musick: so they are often molested with the Frensie invading with madnes and fury; by the heat whereof they are often so ravished and carried beside themselves that they foretell things to come; they are terrified with horrible dreams, and in their fits they speak in strange and forain tongues, but they are so subject to the scurfe and all kind of scabs and to the Leprosie as their homebred disease, that no houses are so frequently met withall by such as travell through either of the Mauritania's, as Hospitalls provided for the Lodging of Leapers.

Those who inhabit rough and Mountainous places, are more brutish, tough and able to indure labour: but such as dwell in Plains, especially if they be moorish, or fennish, are of a tender body, and sweat much with a little labour; the truth of which is confirmed by the Hollanders and Frizlanders. But if the Plain be such as is scorched by the heat of the Sun, and blown upon by much contrariety of winds, it breeds men who are turbulent, not to be tamed, desirous of sedition and novelty, stubborn, impatient of servitude, as may be perceived by the sole example of the Inhabitants of *Narbon* a province of *France*.

Those who dwell in poor and barren places are commonly more witty and diligent and most patient of labours; the truth of which the famous wits of the *Athenians*, *Ligurians* and *Romans*, and the plain country of the *Bœotians* in *Greece*, of the *Campanians* in *Italy*, and of the rest of the Inhabiters adjoining to the *Ligurian* Sea, approves.

The East wind healthfull.

The Northern people great eaters and drinkers.

Who are to be counted Barbarous. The Northern and Southern have each their Cruelties.

Valer. Max. lib. 9. cap. 7.

The diseases of the Southern people.

Mountainers.

CHAP. VIII.

Of the Faculties.

Faculty is a certain power, and efficient cause, proceeding from the temperament of the part, and the performer of some actions of the body. There are three principall Faculties governing mans body as long as it enjoyes its integrity; the Animall, Vital and Natural. The Animall is seated in the proper temperament of the Brain, from whence it is distributed by the Nerves into all parts of the body wch have sense & motion. This is of three kinds, for one is Moving, another sensitive, the third principall. The sensitive consists in the five external senses, sight, hearing, taste, smel & touch. The moving principally remains in the Muscles & nerves as the fit instruments

What a faculty is. 3. Faculties.

of voluntary motion. The Principall comprehends the Reasoning faculty, the Memory and Fantasie. *Galen* would have the common or inward sense to be comprehended within the compass of the Fantasie, although *Aristotle* distinguish between them.

The Vitall abides in the Heart, from whence heat and life is distributed by the Arteries to the whole body: this is principally hindered in the diseases of the Brest; as the Principall is, when any disease assails the Brain; the prime action of the vitall faculty is Pulsation, and that continued agitation of the Heart and Arteries, which is of threefold use to the body: for by the dilatation of the Heart and Arteries the vitall spirit is cherished by the benefit of the Air which is drawn in; by the contraction thereof the vapours of it are purged and sent forth, and the native heat of the whole body is tempered by them both.

The last is the Naturall faculty which hath chosen its principall seat in the Liver, it spreads or carries the nourishment over the whole body; but it is distinguished into 3. other faculties; The Generative, which serves for the generation and forming of the Issue in the wombe; the Growing or increasing faculty, which flourisheth from the time the Issue is formed, untill the perfect growth of the solid parts into their full dimensions of length, height and breadth. The nourishing faculty, which as servant to both the other repairs and repays the continuall efflux, and waste of the threefold substance; for Nutrition is nothing else but a replenishing, or repairing whatsoever is wasted or emptied. This nourishing faculty endures from that time the Infant is formed in the wombe untill the end of life. It is a matter of great consequence in Physick to know the 4. other faculties, which as servants attend upon the nourishing faculty; which are the Attractive, Retentive, Digestive, and Expulsive faculty. The Attractive draws that juyce which is fit to nourish the body, that I say which by application may be assimilated to the part. This is that faculty which in such as are hungry draws down the meat scarce chewed, and the drink scarce tasted, into the gnawing and empty stomach. The Retentive faculty is that which retains the nourishment once attracted untill it be fully laboured and perfectly concocted; And by that means it yeelds no small assistance to the Digestive faculty. For the naturall heat cannot perform the office of concoction, unless the meat be embraced by the part, and make some stay therein. For otherwise the meat carryed into the stomach never acquires the form of *Chylus*, unless it stay detained, in the wrinkles thereof, as in a rough passage, untill the time of *Chylification*. The Digestive faculty assimilates the nourishment, being attracted and detained, into the substance of that part whose faculty it is, by the force of the inbred heat and proper disposition or temper of the part. So the stomach plainly changes all things which are eat and drunk into *Chylus*, and the Liver turns the *Chylus* into blood. But the Bones and Nerves convert the red and liquid blood which is brought down unto them by the capillary or small veins, into a white and solid substance. Such concoction is far more laborious in a Bone and Nerve, than in the Musculous flesh, For the blood being not much different from its nature, by a light change and concretion turns into flesh. But this Concoction will never satisfie the desire of Nature and the parts, unless the nourishment purged from its excrements, put away the filth and dross, which must never enter into the substance of the part. Wherefore there do not only two sorts of excrements remain of the first and second Concoction, the one thick, the other thin, as we have said before; but also from the third Concoction which is performed in every part. The one of which we conceive only by reason, being that which vanisheth into Air by insensible transpiration. The other is known sometimes by sweats, sometimes by a thick fatty substance staining the shirt; sometimes by the generation of hairs and nails, whose matter is from fuliginous and earthly excrements of the third Concoction. Wherefore the fourth faculty was necessary which might yeeld no small help to nourishment; it is called the Expulsive, appointed to expell those superfluous excrements which by no action of heat, can obtain the form of the part. Such faculties serving for nutrition are in some parts two-fold; as some common, the benefit of which redounds to the whole body, as in the ventricle, liver and veins; Others only attending the service of those parts in which they remain, and in some parts all these 4. as well common as proper, are abiding and residing as in those parts we now mentioned: some with the 4. proper have only two common, as the Gall, Spleen, Kidnies and Bladder. Others are content only with the proper, as the similar and Musculous parts, who if they want any of these 4. faculties, their health is decayed either by want of nourishment, and ulcer, or otherwise. The like unnatural affects happen by the deficiency of just and laudable nourishment. But if it happen those faculties do rightly perform their duty, the nourishment is changed into the proper part, and is truly assimilated as by these degrees. First it must flow to the part, then be joynd to it, then agglutinated, and lastly as we have said, assimilated. Now we must speak of the Actions which arise from the faculties.

The triple use of the Pulse.

The naturall faculty is threefold.

What Nutrition is.

Four other faculties attend upon the nourishing faculty.

The necessity of the retentive faculty.

Two excrements of every concoction.

The work of the expulsive faculty.

By what degrees the nourishment is assimilated.

CHAP. IX.

Of the Actions.

AN Action or Function is an active motion proceeding from a faculty; for as the faculty depends on the Temperament, so the Action on the faculty, and the Act or work depends upon the Action by a certain order of consequence. But although that the words Action and Act or work are often confounded, yet there is this difference between them, as that the Action signifies the motion used in the performance of any thing; but the Act or work, the thing already done and performed: for example, Nutrition and the Generating of flesh are naturall Actions; but the parts nourished, and a hallow ulcer filled with flesh are the works of that motion, or action. Wherefore the Act ariseth from the Action, as the Action ariseth from the faculty, the integrity or perfection of the instruments concurring in both. For as, if the faculty be either defective, or hurt, no Action will be well performed: so unless the Instruments keep their native and due conformity (which is their perfect health, the operator of the Action proper to the instrument) none of those things, which ought to be, will be well performed. Therefore for the performance of blameless and perfect actions, it is fit a due conformity of the instrument concur with the faculty. But Actions are two fold; for they are either Naturall, or Voluntary. They are tearmed Naturall, because they are performed not by our will, but by their own accord and against our will: As are, that continuall motion of the Heart, the beating of the Arteries, the expulsion of the Excrements, and such other like which are done in us by the Law of Nature whether we will, or no. These Actions flow either from the Liver and veins, or from the Heart and Arteries. Wherefore we may comprehend them under the names of Naturall and Vitall Actions. For we must attribute his Action to each faculty, lest we may seem to constitute an idle faculty, and no way profitable for use. The unvoluntary vitall actions, are the dilatation and contraction of the Heart and Arteries, the which we comprehend under the sole name of the Pulse: by that they draw in, and by this they expell, or drive forth. The unvoluntary vitall actions be,

Generation }
 Growth and } which proceed from the } Generative
 Nutrition } } Growing, and } facultie.
 } } Nourishing }

Generation is nothing else then a certain producing or acquiring of matter, and an introducing of a substantiall form into that matter; this is performed by the assistance of two faculties; of the Altering, which doth diversly prepare and dispose the seed and menstruous blood to put on the form of a Bone, nerve, spleen, flesh and such like: of the Forming faculty, which adorns with figure, site, and composition, the matter ordered by so various a preparation.

Growth is an enlarging of the solid parts into all the dimensions, the pristine and ancient form remaining safe and sound in figure and solidity. For the perfection of every growth is judged only by the solid parts; for if the body swell into a mass of flesh, or fat, it shall not therefore be said to be grown: but then only when the solid parts do in like manner increase, especially the bones, because the growth of the whole body follows their increase, even although at the same time it wax lean and pine away.

Nutrition is a perfect assimilation of that nourishment which is digested, into the nature of the part which digests. It is performed by the assistance of 4. subsidiary or helping actions, Attractive, Retentive, Digestive, and Expulsive.

The voluntary actions which we willingly perform, are so called, because we can at our pleasure hinder, stir up, slow or quicken them. They are three in generall, the sensitive, moving, and principall Action. The sensitive * Soul comprehends all things in five senses; in Sight, Hearing, Smell, Taste and Touch. Three things must necessarily concur to the performance of them, the Organ, the Medium or mean, and the Object. The principall Organ, or Instrument, is the Animall spirit diffused by the nerves into each several part of the body, by which such actions are performed. Wherefore for the present we will use the Parts themselves for their Organs. The Mean is a Body, which carries the Object to the Instrument. The Object is a certain externall quality, which hath power by a fit Medium or Mean to stir up and alter the Organ. This will be more manifest by relating the particular functions of the senses by the necessary concurring of these three.

Sight, is an action of the seeing faculty, which is done by the Eye, fitly composed of its coats and humors, and so consequently the Organicall body of this Action. The Object is a visible quality brought to the Eye. But such an Object is twofold; for either it is absolutely visible of its self, and by its own Nature, as the Sun, the fire, the Moon and Stars: or desires as it were the help of another that it may be actually such, for so by the coming of the light colours, which were visible in power onely, being brought to the Eye, they do seem and appear such as they actually are.

What an Action is.

An action and Act are different.

Naturall actions.

What Growth is.

What Nutrition is.

Action voluntary. * Anima sensitive.

How sight is performed.

But such Objects cannot arrive at the Eye, but through a clear and illuminate *Medium*, as the Air, Water, Glasse and all sorts of Cryfall.

How hearing. The Hearing hath for its Organ the Ear and Auditory passage, which goes to the stony bone furnished with a Membrane investing it, an Auditory Nerve, and a certain inward spirit there contained. The Object is every sound arising from the smitten or broken Air, and the Collision of two bodies meeting together. The *Medium* is the encompassing Air which carries the sound to the Ear.

How smelling. Smelling (according to *Galens* opinion) is performed in the Mamillary processes produced from the proper substance of the brain, and seated in the upper part of the nose: although others had rather smelling should be made in the very foremost ventricles of the brain. This Action is weak in man in comparison of other Creatures: the Object thereof is every smell, or fœtid exhalation breathing out of bodies. The *Medium* by which the Object is carried to the noses of Men, Beasts and Birds, is the Air, but to

How the taste. Fishes the Water it self. The Action of taste is performed by the tongue being tempered well and according to nature, and furnished with a nerve spread over its upper part from the third and fourth conjugation of the brain. The Object is * Taste, of whose nature and kinds we will treat more at large in our Antidotary. The *Medium* by the which the Object is so carried to the Organ, that it may affect it, is either externall or internall: The externall is that spittle which doth as it were anoint and supple the tongue; the internall is the spongy flesh of the tongue it self, which affected with the quality of the Object doth presently so possess the nerve that is implanted in it, that the kind and quality thereof

How touching. by the force of the spirit may be carryed into the common sense. All parts endued with a nerve enjoy the sense of touching, which is chiefly done, when a tractable quality doth penetrate even to the true and nervous skin, which lyeth under the Cuticle, or scarf-skin; we have formerly noted, that it is most exquisite in the skin which invests the ends of the fingers. The Object is every tractable quality, whether it be of the first rank of qualities, as Heat, Cold, Moisture, Dryness, or of the second, as Roughness, Smoothness, Heaviness, Lightness, Hardness, Softness, Rarity, Density, Friability, Unctuousity, Grossness, Thinness. The *Medium* by whose procurement the instrument is affected, is either the skin or the flesh interwoven with many Nerves.

Of motion. The next Action, is that Motion, which by a peculiar name we call voluntary; this is performed and accomplished by a Muscle, being the proper Instrument of voluntary Motion. Furthermore every motion of a member possessing a Muscle is made either by bending and contraction, or by extention. Although generally there be so many differences of voluntary motion, as there are kinds of site in place; therefore Motion is said to be made upward, downward, to the right hand, to the left, forward and backward; Hither are referred the many kinds of motions, which the infinite variety of Muscles produce in the body. Into this rank of Voluntary Actions, comes Respiration, or breathing, because it is done by the help of the Muscles; although it be chiefly to temper the heat of the Heart. For we can make it more quick, or slow as we please, which are the conditions of a voluntary Motion.

How respiration may be a voluntary motion.

Lastly, that we may have somewhat in which we may safely rest and defend our selves against the many questions which are commonly moved concerning this thing, we must hold, that Respiration is undergone and performed by the Animall faculty, but chiefly instituted for the vitall.

The third principall Action.

The principall Action and prime amongst the Voluntary is absolutely divided in three, Imagination, Reasoning and Memory.

Imagination is a certain expressing, and apprehension which discerns and distinguisheth between the forms and shapes of things sensible, or which are known by the senses.

Reasoning is a certain judicial estimation of conceived or apprehended forms or figures, by a mutuall collating or comparing them together.

Memory is the sure storer of all things, and as it were the Treasury which the mind often unfolds and opens, the other faculties of the mind being idle and not employed. But because all the forementioned Actions whether they be Naturall, or Animall and voluntary, are done and performed by the help and assistance of the Spirits; therefore now we must speak of the Spirits.

CHAP. X.

Of the Spirits.

What a spirit is.

The Spirit is a subtile and aery substance, raised from the purer blood that it might be a vehicle for the faculties (by whose power the whole body is governed) to all the parts, and the prime instrument for the performance of their office. For they being destitute of its sweet approach doe presently cease from action, and as dead do rest from their accustomed labours. From hence it

is that making a variety of Spirits according to the number of the faculties, they have divided them into three; as one Animall, another Vitall, another Naturall.

Spirits three-fold.

The Animall hath taken his seat in the brain; for there it is prepared and made, that from thence conveyed by the Nerves, it may impart the power of sense and motion to all the rest of the members. An argument hereof is, that in the great cold of Winter, whether by the intercepting them in their way, or by the concretion, or, as it were, freezing of those spirits the joynts grow stiff, the hands numb, and all the other parts are dull, destitute of their accustomed agility of motion, and quickness of sense. It is called Animall, not because it is the * Life, but the chief and prime instrument thereof: wherefore it hath a most subtil and aery substance; and enjoys divers names, according to the various condition of the Sensories or seats of the senses into which it enters; for that which causeth the sight, is named the Visive: you may see this by night, rubbing your eyes, as sparkling like fire. That which is conveyed to the Auditory passage, is called the Auditive or Hearing: That which is carried to the instruments of Touching, is termed the Tactive; and so of the rest.

The Animall spirit.

Why so called.
* Anima.

This Animall spirit is made and laboured in the windings and foldings of the Veins and Arteries of the brain, of an exquisit subtil portion of the vitall brought thither by the *Carotide Arterie*, or sleepy Arteries; and sometimes also of the pure air, or sweet vapour drawn in by the Nose in breathing. Hence it is, that with Ligatures we stop the passage of this spirit, from the parts we intend to cut off. An Humor which obstructs or stops its passage, doth the like in Apoplexies and Palsies, whereby it happens that the members situate under that place do languish and seem dead, sometimes destitute of motion, sometimes wanting both sense and motion.

How it is made?

The Vitall spirit is next to it in dignity and excellency, which hath its chief mansion in the left ventricle of the Heart, from whence, through the Channels of the Arteries, it flows into the whole body, to nourish the heat which resides fixed in the substance of each part, which would perish in short time, unless it should be refreshed by heat flowing thither together with the spirit. And because it is the most subtil next to the Animall, Nature (lest it should vanish away) would have it contained in the Nervous coat of an Artery, which is five times more thick than the coat of the Veins, as *Galen*, out of *Herophilus*, hath recorded.

The Vitall spirit.

It is furnished with matter from the subtil exhalation of the blood, and that air which we draw in breathing. Wherefore it doth easily and quickly perish by immoderate dissipations of the spirituous substance, and great evacuations; so it is easily corrupted by the putrefaction of Humors, or breathing in of pestilent air and filthy vapours; which thing is the cause of the so suddain death of those which are infected with the Plague. This spirit is often hindered from entering into some part, by reason of obstruction, fulness, or great inflammations; whereby it follows, that in a short space, by reason of the decay of the fixed and inbred heat, the parts do easily fall into a Gangrene, and become mortified.

What the matter of it is.

The Naturall spirit (if such there be any) hath its station in the liver and Veins. It is more gross and dull than the other, and inferior to them in the dignity of the Action, and the excellency of the use. The use thereof is to help the concoction both of the whole body, as also of each severall part, and to carry blood and heat to them.

There is some doubt of the Naturall spirit.

Besides those already mentioned, there are other Spirits fixed and implanted in the similar and prime parts of the body, which also are naturall, and Natives of the same place in which they are seated and placed. And because they are also of an aery and fiery nature, they are so joined or rather united to the Native heat, that they can no more be separated from it than flame from heat; wherefore they with these that flow to them, are the principall instruments of the Actions which are performed in each severall part; And these fixed Spirits have their nourishment and maintenance from the radicall and first-bred moisture, which is of an aery and oily substance, and is, as it were, the foundation of these Spirits, and the inbred heat. Therefore without this moisture, no man can live a moment. But also the chief Instruments of life are these Spirits, together with the Native heat. Wherefore this radicall Moisture being dissipated and wasted, (which is the seat, fodder, and nourishment of the Spirits and heat) how can they any longer subsist and remain? Therefore the consumption of the naturall heat, followeth the decay of this sweet and substance-making moisture, and consequently death, which happens by the dissipating and resolving of naturall heat.

Fixed Spirits.

The radicall Moisture.

But since then these kind of Spirits with the naturall heat, is contained in the substance of each similar part of our body, (for otherwise it could not persist) it must necessarily follow, that there be as many kinds of fixed Spirits, as of similar parts. For because each part hath its proper temper and encrease, it hath also its proper Spirit, and also its own proper fixed and implanted heat, which here hath its abode, as well as its Originall. Wherefore the Spirit and heat which is seated in the bone, is different from that which is imparted into the substance of a Nerve, Vein, or such other similar part; because the temper of these parts is different, as also the mixture of the Elements from which they first arose and sprung up. Neither is this contemplation of Spirits of small account, for in these consist all the force and efficacy of our Nature.

Naturall death.

These

The use and necessity of the Spirits.

What the remedy for the dissipation of the Spirits. What the remedy for oppression of the Spirits is.

These being by any chance dissipated or wasted, we languish; neither is any health to be hoped for, the flour of life withering and decaying by little and little. Which thing ought to make us more diligent, to defend them against the continuall efflux of the threefold substance. For if they be decayed, there is left no proper indication of curing the disease; so that we are often constrained, all other care laid aside, to betake our selves to the restoring and repairing the decayed powers. Which is done by meats of good juice, easie to be concocted and distributed; good Wines, and fragrant smels.

But sometimes these Spirits are not dissipated, but driven in and returned to their fountains, and so both oppress and are oppress; whereupon it happens we are often forced to dilate and spread them abroad by binding and rubbing the parts. Hitherto we have spoke of these things which are called Naturall, because we naturally consist of them; it remains that we now say somewhat of their Adjuncts and Associates by familiarity of Condition.

The Adjuncts and Associates to things Naturall: are,

Age: of which, by reason of the similitude of the Argument, we were constrained to speak, when we handled the Temperatures.

Sex.

Colour: of which we have already spoken.

The conformation of the *Instrumentall* parts.

Time: whose force we have also considered.

Region.

Order of *Diet*, and condition of *Life*.

CHAP. XI.

Of the Adjuncts of things Naturall.

What sex is.

The nature of women.

Of Eunuchs.

Of Hermaphrodites.

Colour the bewrayer of the Temperament.

The perfection of the organick parts, consists in four things.

SEX is no other thing than the distinction of Male and Female; in which this is most observable, that for the parts of the body, and the site of these parts, there is little difference between them; but the Female is colder than the Male. Wherefore their spermaticall parts are more cold, soft, and moist; and all their naturall actions less vigorous and more depraved.

The Nature of Eunuchs is to be referred to that of women, as who may seem to have degenerated into a womanish nature, by deficiency of heat; their smooth body, and soft and shrill voice do very much assimilate women. Notwithstanding you must consider, that there be some Manly women, which their manly voice, and chin covered with a little hairiness, do argue: and on the contrary, there are some womanizing, or womanish men, which therefore we term dainty and effeminate.

The Hermaphrodite is of a doubtful nature, and in the middle of both sexes seems to participate of both Male and Female.

The Colour which is predominant in the habit and superficies of the body, and lyes next under the skin, shews the Temperament of what kind soever it be; for as *Galen* notes in *Comment. ad Aphor. 2. sect. 1.* Such a colour appears in us, as the contained Humor hath. Wherefore if a rosie hew colour the cheeks, it is a sign the body abounds with blood, and that it is carried abroad by the plenty of Spirits. But if the skin be dyed with a yellow colour, it argues Choler is predominant; if with a whitish and pallid hue, Phlegm; with a sable and duskie, Melancholy. So the colour of the Excrements which are according to Nature, is not of the least consideration. For thus, if an Ulcer being broken send forth white matter, it argues the soundness of the part from whence it flows; but if sanious or bloody, green, blackish, or of divers colours, it shews the weakness of the solid part, which could not assimilate by concoction the colour of the excrementitious humor. The like reason is of unnaturall Tumors: For, as the colour, so the dominion of the Humor causing or accompanying the swelling commonly is.

The conformity and integrity of the Organick parts is considered by their figure, greatness, number, situation, and mutuall connexion. We consider the figure, when we say, almost all the externall parts of the body are naturally round, not only for shew, but for necessity, that being smooth and no way cornered, they should be less obnoxious to externall injuries; we speak of Greatness, when we say, some are large and thick, some lank and lean. But we consider their Number, when we observe some parts to abound, some to want, or nothing to be defective or wanting. We insinuate Site and Connexion, when we search, whether every thing be in its proper place, and whether they be decently fitted, and well joined together.

We have handled the varieties of the four seasons of the Year, when we treated of Temperaments. But the consideration of the Region (because it hath the same judgment that the Air) shall be referred to that disquisition or enquiry which we intend to make of the Air, amongst the things not naturall.

The manner of life, and order of Diet are to be diligently observed by us, because they have great power either to alter, or preserve the Temperament. But because they are of almost infinite variety, therefore they scarce seem possible to fall into Art, which may prosecute all the differences of Diet and Vocations of life. Wherefore if the Calling of Life be laborious, as that of Husbandmen, Mariners, and other such trades, it strengthens and dries the parts of the body. Although those which labour much about Waters, are most commonly troubled with cold and moist diseases, although they almost kill themselves with labour.

Diet.

Again, those which deal with Metals, as all sorts of Smiths, and those which cast and work brass, are more troubled with hot diseases, as Feavers. But if their Calling be such, as they sit much, and work all the day long sitting at home, as shoemakers; it makes the body tender, the flesh effeminate, and causeth great quantity of excrements. A life as well idle and negligent in body, as quiet in mind, in all riotousness and excesses of Diet, doth the same. For from hence the body is made subject to the Stone, Gravel, and Gout.

That calling of life which is performed with moderate labour, clothing, and diet, seems very fit and convenient to preserve the naturall temper of the body. The ingenious Chirurgeon may frame more of himself that may more particularly conduce to the examination of these things. Therefore the things naturall, and those which are near or neighbouring to them being thus briefly declared; the Order seems to require, that we make enquiry of things not Naturall.

The commodities of an indifferent Diet.

CHAP. XII.

Of things not Naturall.

He things which we must now treat of, have by the later Physitians been termed Not-naturall; because they are not of the number of those which enter into the constitution or compofure of mans body; as the Elements, Humors, and all such things which we formerly comprehended under the name of Natural: although they be such as are necessary to preserve and defend the body already made and composed. Wherefore they were called by *Galen* Preservers; because by the due use of them the body is preserved in health. Also, they may be called Doubtfull, and Neuters, for that rightly and fitly used, they keep the body healthfull, but inconsiderately, they cause diseases. Whereby it comes to pass, that they may be thought to pertain to that part of Physick which is of preserving health; not because some of these things should be absolutely and of their own nature wholsom, and others unwholsom; but only by this, that they are, or prove so by their convenient, or preposterous use. Therefore we consider the use of such like things from four conditions, Quantity, Quality, Occasion, and Manner of using: If thou shalt observe these, thou shalt attain and effect this, That those things which are of themselves, are, as it were, doubtfull, shall bring certain and undoubted health. For these four Circumstances do so far extend, that in them, as in the perfection of Art, the Rules which may be prescribed to preserve health are contained. But *Galen* in another place, hath in four words comprehended these things not Naturall; as, things Taken, Applied, Expelled, and to be Done. Things Taken, are those which are put into the body, either by the mouth, or any other way; as the air, meat and drink. Things Applied, are those which must touch the body, as the Air now mentioned, affecting the body with a diverse touch of its qualities of heat, cold, moisture, or driness. Expelled, are what things soever being unprofitable are generated in the body, and require to be expelled. To be Done, are labour, rest, sleep, watching, and the like. We may more distinctly, and by expression of proper Names, revoke all these things to six:

Why they are called things not naturall.

CHAP. XIII.

of the Air.

How necessary
for life the Air
is.

AIR is so necessary to life, that we cannot live a moment without it; if so be that breathing, and much more transpiration, be not to be separated from life. Wherefore it much conduceth to know, what Air is wholesom, what unwholsom, and which by contrariety of qualities fights for the Patient against the disease; or on the contrary by a similitude of qualities shall nourish the disease, that if it may seem to burden the Patient by increasing or adding to the disease, we may correct it by Art. So in curing the wounds of the head, especially in winter, we labour by all the means we may to make the air warm. For cold is hurtfull to the Brain, Bones, and the wounds of these parts; and heat is comfortable and friendly. But also the Air being drawn into the body by breathing when it is hotter than ordinary, doth with a new warmth over-heat the heart, lungs, and spirits, and weaken the strength by the dissipation of the Spirits too much attenuated; so being too cold, in like manner the strength of the faculties faints and grows dull, either by suppression of the vapors, or by the inspissation or thickning of the Spirits.

What Air is
hurtfull.

Therefore to conclude, that Air is to be esteemed healthfull, which is clear, subtil, and pure, free and open on every side, and which is far remote from all carion-like smells of dead carcasses, or the stench of any putrefying thing whatsoever: the which is far distant from standing pools, and fens, and caves, sending forth strong and ill vapors; neither too cloudy nor moist by the nearness of some river.

Such an Air, I say, if it have a vernal temper, is good against all diseases. That Air which is contrary to this, is altogether unhealthfull; as that which is putrid, shut up, and prest by the straitness of neighbouring Mountains, infected with some noisom vapor. And because I cannot prosecute all the conditions of Airs, fit for the expelling of all diseases, as which are almost infinite; it shall suffice here to have set down, what we must understand by this word *Air*.

Three things
are understood
by the name of
the Air.

Physitians commonly use to understand three things by the name of *Air*; The present state of the Air; the Region in which we live; and the season of the Year. We spoke of this last, when we treated of Temperaments. Wherefore we will now speak of the two former. The present state of the Air, one while for some small time, is like the Spring, that is, temperate; otherwhiles like the Summer, that is, hot and dry; otherwhiles like the Winter, that is, cold and moist; and sometimes like the Autumn, which is unequal; and this last constitution of the Air is the cause of many diseases. When upon the same day, it is one while hot, another cold, we must expect Autumnall diseases. These tempers and varieties of constitutions of the Air, are chiefly and principally stirred up by the winds; as which being diffused over all the Air, shew no small force by their sodain change. Wherefore we will briefly touch their natures: That which blows from the East, is called the East-wind, and is of a hot and dry nature, and therefore healthfull. But the Western-wind is cold and moist, and therefore sickly. The South-wind is hot and moist, the Author of putrefaction and putrid diseases. The North-wind is cold and dry, therefore healthy: wherefore it is thought, if it happen to blow in the Dog-days, that it makes the whole year healthfull, and purges and takes away the seeds of putrefaction, if any chance to be in the Air. But this description of the four Winds, is then only thought to be true, if we consider the Winds in their own proper nature, which they borrow from these Regions from which they first proceed. For otherwise they affect the Air quite contrary, according to the disposition of the places over which they came; as Snowie places, Seas, Lakes, Rivers, Woods, or sandy Plains, from whence they may borrow new qualities, with which they may afterwards possess the Air, and so consequently our bodies.

How the winds
acquire other
faculties, than
they naturally
have.

The Westwind
of it self un-
wholsom.

Hence it is we have noted the Western-wind unwholsom, and breeding diseases, by reason of the proper condition of the Region from whence it came; and such, that is cold and moist; the *Gascoins* find it truly to their so great harm, that it seldom blows with them, but it brings some manifest and great harm, either to their bodies, or fruits of the earth. And yet the *Greeks* and *Latins* are wont to commend it for healthfulness, more than the rest. But also the rising and setting of some more eminent stars, do often cause such cold winds, that the whole Air is cooled, or infected with some other malign quality. For vapors and exhalations are often raised by the force of the Stars, from whence winds, clouds, storms, whirlwinds, lightnings, thunders, hail, snow, rain, earthquakes, inundations, and violent raging of the sea, have their originall. The exact contemplation of which things, although it be proper to Astronomers, Cosmographers, and Geographers, yet *Hippocrates* could not omit it, but that he must speak something in his book *De Aère & Aquis*; where he touches by the way, the description of the neighbouring Regions, and such as he knew.

What force
Stars have upon
the Air.

From this force of the Air, either hurtfull, or helping in diseases, came that famous observa-

observation of *Guido of Caulus*; That wounds of the head are more difficult to cure at *Paris*, than at *Avignon*, and the plain contrary of wounds of the legs; for the air of *Paris*, compared to that of *Avignon*, is cold and moist, wherefore hurtfull and offensive to the wounds of the head. On the contrary, the same air, because it obscures the spirits, in-crassates the blood, condensates the humors, and makes them less fit for defluxions, makes the wounds of the legs more easie to be healed, by reason it hinders the course of the humors, by whose defluxion the cure is hindred. But it is manifest, that hot and dry places make a greater dissipation of the naturall heat, from whence the weakness of the powers; by which same reason, the Inhabitants of such places do not so well endure blood-letting; but more easly suffer purgations, though vehement, by reason of the contumacie of the humor, caused by driness. To conclude, the Air changes the constitutions of our bodies, either by its qualities, as if it be hotter, colder, moister, or drier; or by its matter, as if it be grosser, or more subtil than is fit, or corrupted by exhalations from the earth, or by a sodain and unaccustomed alteration, which any man may prove, who makes a sodain change out of a quiet air into a stormy and troubled with many winds. But because, next to the Air, nothing is so necessary to nourish mans body, as Meat and Drink, I will now begin to speak of them both.

How the air of *Paris* comes to be ill for wounds of the head, and good for those of the leggs.

By what means the air changes our bodies.

CHAP. XIII.

Of Meat and Drink.

That this our Treatise of meat and drink may be more brief and plain, I have thought good to part it into these heads, as to consider the goodness and illness of both of them, their quantity, quality, custom, delight, order, time, and to accommodate them all to the ages and seasons of the year. We judge of the goodness and pravity of meats and drinks, from the condition of the good or vicious humours, or juice which they beget in us. For evill juice causeth many diseases. As on the contrary, good juice drives away all diseases from the body, except the fault happen from some other occasion, as from quantity, or too much excess. Wherefore it is principally necessary, that those who will preserve their present health, and hinder the access of diseases, feed upon things of good nourishment and digestion, as are good wine, the yolks of eggs, good milk, wheaten bread well baked, the flesh of Capons, Partridge, Thrushes, Larks, Veal, Mutton, Kid, and such like other, which you may find mentioned in the Books which *Galen* writ, *De Alimentorum facultatibus*; where also he examines those which are of evill juice, by their manifest qualities, as acrimony, bitterness, saltness, acidity, harshness, and such like.

The goodness of nourishments,

But unless we use a convenient quantity and measure in our meats, howsoever laudable they be, we shall never reap these fruits of health we hoped for. For they yeeld matter of diseases, by the only excess of their quantity; but we may by this know the force of quantity on both parts, because often the poisonous quality of meats of ill nourishment doth not hurt, by reason they were not taken into the body into a great quantity. That measure of quantity is chiefly to be regarded in diseases: for as *Hippocrates* saith, If any give meat to one sick of a Fever, he gives strength to the well, and increases the disease to the sick, especially if he do not use a mean. Wherefore it is a thing of no small consequence, to know what diseases require a slender, and what a large diet; of which thing there is large relation made in the 1 *Sect.* of the Aphorisms of *Hippocrates*; where he teacheth, the sick must feed more largely in the beginnings of long diseases, whereby they may be enabled to endure the length of the disease, and last to the state thereof. But in sharp and violent diseases, which presently come to their height, we must use a slender diet; but most slender, when the disease is in the height; and besides, all our consultations in this kinde, must be referred to the strength of the Patients. But those who enjoy their perfect health, must use a quantity of meat, agreeable to their evacuation and transpiration; for men, by reason of the strength of their heat, and the more copious dissipation of the triple substance, have greater appetite than women; altogether by the same reason, that young people, and such as grow, need more frequent and plentiful nourishment, than old men; and also amongst young men of the like age, some do rightly require more copious nourishment than other some, that is, according to the quantity of their evacuations and custom. Certainly for gluttony, it is such as may be extended to all; but we all should take so much meat and drink, that our powers may be refreshed and not oppressed; for by the decree of *Hippocrates*, these be the two compendiary ways of preserving health; not to be over-filled with meat, and to be quick to work; and thus much of the quantity of meats. Neither must these who are either sound, or sick, have less regard to the qualities of their Meats; and those are either the first, as heating, cooling, moistening, drying; or the second, attenuating, in-crassating, obstructing, opening, or some other-like, working according to the condition of their nature. The manner of our diet is not only to be framed according

Their quantity

The quantity of meats must be esteemed according to the nature of the disease, and strength of the Patient.

The qualities of meat.

to these, but also to be varied; for the present state of such as be in health, requires to be preserved by the use of like things. As hot and moist nourishment is to be prescribed to children, as to those which are hot and moist: and cold and dry to old men, as to those who are cold and dry; if so be that vulgar saying be true, that, *Health delights in the use of like things*. Yet because Old-age how green and new-begun howsoever it be, is of it self, as it were, a disease, it seems to be more convenient, both to truth, and for health, that old people should eat meats contrary to their nature, that is, hot and moist, that so we may defer as much as we can, the causes of death, cold and driness, which hasten the destruction of that age. For we must resist diseases by the use of their contraries, as those things which are contrary to nature. For otherwise, as much meat as you give to the sick, you add so much strength to the disease. And the same is the cause why *Hippocrates* said, that a moist diet is convenient for all such as are sick of Feavers, because a Fever is a dry distemperature. Therefore we must diligently pry into the nature of the disease, that knowing it, we may endeavour to abate its fury by the use of contraries.

Old-age is a disease,

Aphor. 16.
sect. 1.

The force of Custom.

Aphor. 91.
sect. 2.

Aphor. 38.
sect. 2.

Accustomed meats are more gratefull, and so by that means more nourishing.

But if Custom (as they say) be another nature, the Physitian must have a great care of it, both in sound and sick. For this sometimes by little and little, and insensibly, changes our naturall temperament, and in stead thereof gives us a borrowed temper. Wherefore if any would presently or sodainly change a Custom which is sometimes ill, into a better, truly he will bring more harm than good; because all sodain changes (according to the opinion of *Hippocrates*) are dangerous. Wherefore if necessity require that we should withdraw any thing from our Custom, we must do it by little and little, that so nature may by degrees be accustomed to contraries without violence, or the disturbance of its usuall government. For that meat and drink which is somewhat worse, but more pleasant and familiar by custom, is to be preferred (in *Hippocrates* opinion) before better, but less pleasant and accustomed. Hence is it, that Country-men do very well digest Beef and Bacon, which commonly they use; but will turn into nidorous vapors, Partridge, Capons, and other meat of good nourishment, sooner than change them into good and laudable *Chylus*. The cause of which thing is not only to be attributed unto the property of their stronger, & as it were, burning heat, but much more to Custom; which by a certain kind of familiarity, causeth that meats of hard digestion, are easily turned into laudable blood. For the force of Custom is so great, that accustomed Meats are more acceptable; whereby it comes to pass, that while the stomach delights in them, it more straitly embraces them, and happily digests them, without any trouble of loathing, vomiting, or heaviness. All the contrary meet and happen in the use of Meats which are unpleasant to the taste and stomach. For the ventricle abhorring those things, makes manifest how it is troubled by its acide and nidorous belchings, loathing, nauseousness, vomit, heaviness, pain of the head, and trouble of the whole body.

Wherefore we must diligently enquire, what Meats the Patient chiefly delighted in, that by offering them, his appetite languishing by reason of some great evacuation, vomit, or the like, may be stirred up. For it will be better and more readily restored by things acceptable, though they be somewhat worse, as we noted a little before out of *Hippocrates*. By which words he plainly taught, that it is the part of a good and prudent Physitian to subscribe to, and please the palat of his Patient.

The order of eating our meats.

But seeing that order is most beautifull in all things, it is truly very necessary in eating our Meat: for how laudable soever the Meats be in their quantity and quality, howsoever familiar by use, and gratefull by custom, yet unless they be eaten in due order, they will either trouble or molest the stomach, or be ill, or slowly and difficultly concocted; wherefore we must diligently observe, what Meats must be eaten at the first, and what at the second course; for those Meats which be hard to concoct, are not to be eaten before those which are easie of digestion; neither dry and astringent things, before moistening and loosening.

We must begin our meals with moist or liquid meat.

But on the contrary, all slippery, fat, and liquid things, and which are quickly changed, ought to go before, that so the belly may be moistned; and then astringent things must follow, that the stomach, by their help, being shut and drawn together, may more straitly comprehend the Meat on every side, and better perform the Chylification by its proper heat united and joined together.

For this cause *Hippocrates*, *Lib. de victu in acutis*, commands those things to be always eaten in the morning, which are fit to loosen the belly, and in the evenings such as nourish the body. Yet notwithstanding drink ought not to precede or go before meat, but on the contrary meat must precede drink, by the order prescribed by him.

The time of eating.

Whether ought we in our eating to have less care of the time, than we have of the order; for the time of eating of such as are healthfull, ought to be certain and fixt; for at the accustomed hour, and when hunger presses, any sound man, and which is at his own disposal may eat, but exercise and accustomed labors ought to go before; for it is fit, according to the precept of *Hippocrates*, that labor precede meat, whereby the excrements of the third concoction may be evacuated; the native heat increased, and the solid parts confirmed and strengthened, which are three commodities of exercise very necessary to

The profit of labour before meat.

the convenient taking of meat. But in sick persons we can scarce attend and give heed to these circumstances of time, and accustomed hour of feeding; for that Indication of giving meat to the sick, is the best of all, which is drawn from the motion of the disease, and the declining of the fit: for if you give meat in feavers, specially the fit then taking the Patient, you nourish not him, but the disease. For the meat then eaten, is corrupted in the stomach, and yeelds fit matter for the disease: For meat (as we noted before out of Hippocrates) is strength to the sound, and a disease to the sick, unless it be eaten at convenient time, and diligent care be had of the strength of the Patient, and greatness of the disease.

We must not give meat in a fit of a Feaver.

But neither is it convenient that the meat should be simple, and of one kind, but of many sorts, and of divers dishes dressed after different forms, lest nature by the continuall and hatefull feeding upon the same meat, may at the length loath it, and so neither straitly contain it, nor well digest it; or the stomach accustomed to one meat, taking any loathing thereat, may abhor all other; and as there is no desire of that we do not know, so the dejected appetite cannot be delighted and stirred up with the pleasure of any meat which can be offered. For we must not credit those superstitious or too nice Physitians, who think the digestion is hindred by the much variety of meats.

Variety of meats.

The matter is far otherwise, for by the pleasure of what things soever the stomach allured doth require, it embraces them more straitly, and concocts them more perfectly. And our nature is desirous of variety.

Why variety of meats is good.

Moreover, seeing our body is composed of a solid, moist, and airy substance, and it may happen, that by so many labors, which we are compelled to undergo and sustain in this life, one of these may suffer a greater dissipation and loss than another; therefore the stomach is necessarily compelled to seek more variety, lest any thing should be wanting to repair that which is wasted. But also the age and season of the year, yeeld Indications of feeding, for some things are convenient for a young man; some for an old; some in summer, some in winter. Wherefore we ought to know what befits each age and season. Children need hot, moist, and much nourishment, which may not only suffice to nourish, but increase the body. Wherefore they worst endure fasting, and of them, especially those who are the most lively and spiritfull. With old men it is otherwise, for because their heat is small, they need little nourishment, and are extinguished by much. Wherefore old men easily endure to fast; they ought to be nourished with hot and moist meats, by which their solid parts now growing cold and dry, may be heated and moistned, as by the sweet nourishment of such like meats. Middle-ag'd men delight in the moderate use of contraries, to temper the excess of their too acrid heat. Young people as temperate, are to be preserved by the use of like things.

Indications of feeding, taken from the age.

The manner of Diet in Winter must be hot, and inclining to driness. Wherefore then we may more plentifully use roast-meats, strong wines and spices; because in the Winter-season we are troubled with the cold and moist air, and at the same time, have much heat inwardly; for the inner parts, according to Hippocrates, are naturally most hot in the Winter and the Spring, but feaverish in Summer; so the heat of Summer is to be tempered by the use of cold and moist things, and much drink. In the temperate Spring all things must be moderate; but in Autumn, by little and little, we must pass from our Summer to our Winter diet.

Indication from the time of the year.

CHAP. XV.

Of Motion and Rest.

Here Physitians admonish us, that by the name of Motion, we must understand all sorts of exercises, as walking, leaping, running, riding, playing at tennis, carrying a burden, and the like. Friction or rubbing is of this kind, which in times past was in great use and esteem, neither at this day is it altogether neglected by Physitians. They mention many kinds of it, but they may be all reduced to three; as, one gentle, another hard, a third indifferent; and that of the whole body, or only of some part thereof. The Friction is called hard, which is made by the rough, or strong pressure of the hands, sponges, or a course and new linnen cloth: it draws together, condensates, binds and hardens the flesh, yet if it be often and long used, at length it rarifies, dissolves, attenuates, and diminishes the flesh, and any other substance of the body; and also it causeth revulsion, and draws the defluxion of humors from one part to another. The gentle Friction, which is performed by the light rubbing of the hand, and such like, doth the contrary; as, softens, relaxes, and makes the skin smooth and unwrinkled; yet unless it be long continued, it doth none of these worthy to be spoken of. The indifferent kinds, consisting in the mean betwixt the other two, increaseth the flesh, swells or puffs up the habit of the body, because it retains the blood and spirits which it draws; and suffers them not to be dissipated.

What motion signifies.

Three kinds of Frictions.

Hard.

Gentle.

Indifferent.

The use of
exercifes.

The benefit of exercife is great, for it increafes naturall heat, whereby better digeftion follows, and by that means nourifhment, and the expulfion of the excrements; and laftly, a quicker motion of the fpirits, to perform their offices in the body, all the ways and paffages being cleaned. Befides, it ftrengthens the refpiration, and the other actions of the body, confirms the habit, and all the limbs of the body, by the mutuall attrition of the one with the other; whereby it comes to pafs they are not fo quickly wearied with labor. Hence we fee that Country people are not to be tired with labor.

What the fit-
teft time for
exercife.

If any will reap thefe benefits by exercife, it is neceffary that he take opportunity to begin his exercife, and that he feafonably defift from it, not exercifing himfelf violently and without difcretion; but at certain times according to reafon.

Wherefore the beft time for exercife will be before meat (that the appetite may be increafed by augmenting the naturall heat) all the excrements being evacuated, left nature being hungry and empty, do draw and infufe the ill humors contained in the guts and other parts of the body, into the whole habit, the liver, and other noble parts. Neither is it fit prefently, after meat, to run into exercife, left the crude humors and meats not well concocted, be carried into the veins. The meafure and bounds of exercife muft be, when the body appears more full, the face looks red, fweat begins to break forth, we breath more ftrongly and quick, and begin to grow weary; if any continue exercife longer, ftiffnefs and wearinefs affails his joints, and the body flowing with fweat fuffers a lofs of the fpirituos and humid fubftance, which is not eafily repaired; by which it becomes more cold, and lean even to deformity.

The quality
of exercife.

The quality of exercife which we require, is in the midft of exercife, fo that the exercife muft be neither too flow and idle, neither too ftrong nor too weak, neither too hafty nor remifs, but which may move all the the members alike. Such exercife is very fit for found bodies. But if they be diftempered, that fort of exercife is to be made choice of, which by the quality of its excefs, may correct the diftemper of the body, and reduce it to a certain mediocrity. Wherefore fuch men as are ftuffed with cold, grofs, and vifcous humors, fhall hold that kind of exercife moft fit for them, which is more laborious, vehement, ftrong, and longer continued. Yet fo, that they do not enter into it before the firft and fecond concoction, which they may know by the yellownefs of their urine. But let fuch as abound with thin and cholerick humors, chufe gentle exercifes, and fuch as are free from contention, not expecting the finishing of the fecond concoction, for the more acride heat of the folid parts delights in fuch half concocted juices, which otherwife it would fo burn up, all the glutinous fubftance thereof being wafte, that they could not be adjoyned or faftened to the parts. For the repeating or renewing of exercife, the body fhould be fo often exercifed, as there is a defire to eat. For exercife ftirs up and revives the heat which lies buried and hid in the body: for digeftion cannot be well performed by a fluggifh heat; neither have we any benefit by the meat we eat, unlefs we ufe exercife before.

For whom
ftrong exer-
cifes are con-
venient.

* Αποθεμία.

The laft part of exercife begun and performed according to reafon, is named, * *The ordering of the body*, which is performed by an indifferent rubbing and drying of the members; that fo the fweat breaking forth, the filth of the body, and fuch excrements lying under the fkin, may be allured and drawn out; and alfo that the members may be freed from ftiffnefs and wearinefs. At this time it is commonly ufed by fuch as play at Tennis.

What difcom-
modities pro-
ceed from idle-
nefs.

But, as many and great commodities arife from exercife conveniently begun and performed, fo great harm proceeds of idlenefs; for grofs and vicious juices heaped up in the body commonly produce crudities, obftructions, ftones both in the reins and bladder, the Gout, Apoplexie, and a thoufand other difeafes.

C H A P. X V I.

Of Sleep and Watching.

That this our fpeech of Sleep and Watching, which we now intend, may be more plain, we will briefly declare, what commodity or difcommodity they bring; what time and what hour is convenient for both; what the manner of lying muft be, and the choice thereof; what the dreams in fleeping, and what pains or heavinefs and chearfulnefs after fleep may portend.

What fleep is;

Sleep is nothing elfe than the reft of the whole body, and the ceffation of the Animall faculty from fenfe and motion. Sleep is caufed, when the fubftance of the brain is poffeffed, and after fome fort overcome and dulled by a certain vaporos, fweet and delightful humidity; or when the fpirits almoft exhaust by performance of fome labor, cannot any longer fuftain the weight of the body, but caufe reft by a neceffary confequence, by which means nature may produce other from the meat by concoction turned into blood.

The ufe of
fleep.

Sleep fitly taken much helps the digeftion of the parts, becaufe in the time of reft, the heat being the worker of all concoction, is carried back to them, together with the fpirits

spirits. Neither doth sleep only give ease to the wearied members, but also lessens our cares, and makes us to forget our labors.

The night is a fit time to sleep and to take our rest in, as inviting sleep by its moisture, silence and darkness. For the heat and Spirits in the thick obscurity of night, are driven in and retained in the center of the body; as on the contrary by the daily, and as it were, friendly and familiar light of the Sun, they are allured and drawn forth into the superficies, and outward part of the body; from whence they leave sleeping, and begin to wake. Besides also, which makes not a little to that opportunity and benefit which we look for from sleep, the night season suffices for the work of just and perfect concoction. Which is one reason amongst many that sleep on the day time may be hurtfull. For we are wakned from our sleep by the heat and spirits, called forth to the skin either by the light, or noise on the day time, before that the concoction which was begun be finished. But that sleep cannot but be light which comes without necessity of sleeping. Wherefore the concoction being attempted, but not perfected, the stomach is filled with crudities, distended with acide or sour belchings, and the brain troubled with gross vapors and excrementitious humidities. From whence proceeds pain and heaviness of the head, and sore of cold diseases. But although sleep on the night time be wholesome, yet it is fit, that it be restrained within the limits of an indifferent time. For that which exceeds, hinders the evacuation of excrements both upwards and downwards: but in the mean time the heat which is never idle, draws from them some portion or vapor into the veins, principall parts and habit of the body, to become matter for some disease. We must measure this time, not by the space of hours, but by the finishing the work of concoction, which is performed in some sooner than in other some. Yet that which is longest is perfected and done in seven or eight hours. The ventricle subsiding and falling into its self and its proper coats, and the urine tintured yellow, gives perfect judgment thereof. For on the contrary the extension of the stomach, acide belching, pain of the head, and heaviness of the whole body, shew that the concoction is unperfect.

In sleeping we must have special care of our lying down; for first we must lye on our right side, that so the meat may fall into the bottom of our stomach, which being fleshy, and less membranous, is the hotter, and more powerfull to assimilate. Then a little after we must turn upon our left side, that so the Liver with its Lobes, as with hands may on every side embrace the ventricle, and as fire put under a kettle, hasten the concoction. Lastly, towards morning it will not be unprofitable to turn again upon our right side, that by this situation the mouth of the stomach being opened, the vapors which arise from the elixation of the *Chylus* may have freer passage. Lying upon the back is wholly to be avoided; for from hence the Reins are inflamed, the Stone is bred, Palsies, Convulsion, and all diseases which have their originall from the defluxion into the spinall marrow, and to the Nerves taking beginning from thence. To lye upon the belly is not unprofitable for such as have used to lye so, if they be not troubled with defluxions into the eys; for so the humor will more easily flow into the part affected. But thus the work of concoction is not a little furthered, because by that form of lying, not only the inward heat is contained and gathered together about the ventricle, but the encompassing warmness of the soft feathers of the bed aids and assists it.

Neither are the Dreams which we have in our sleep to be neglected, for by the diligent consideration of these, the affections and superfluous Humors which have chief power in the body are marvailously known. For those who have raging choler running up and down their bodies while they sleep, all things to them appear bright, shining, fiery, burning, full of noise and contention. Those who abound with Phlegm, dream of floods, snows, showers, and inundations and falling from high places. Those who are Melancholy dream of gapings and gulfs in the earth, thick and obscure darkness, smokes, caves, and all black and dismall things. But those whose bodies abound in blood, dream of marriages, dances, embracings of women, feasts, jests, laughter, of orchards and gardens; and to conclude, of all things pleasant and splendent.

Also we must observe how the Patient doth after sleep, whether more lively and chearfull, or more heavie: for by the opinion of *Hippocrates*,

*Cum labor a somno est, lethalem collige morbum:
Sin prosit somnus, nihil hinc lethale timendum est.*

Fit time for sleep and the nature of the night.

Sleep on the day-time.

There ought to be a moderation of our nights sleep.

How to be known.

What the form and fire of our body ought to be while we sleep.

The harm of lying on our backs.

Upon our bellies.

The consideration of dreams.

Aphor. 1. sect. 2.

Pain sleep ensuing, an ill disease doth show:
But if sleep profit bring, no harm from thence will flow.

And as sleep, so watching, if it exceed measure, is hurtfull; for it hurts the temperature of the brain, weakens the senses, wastes the spirits, breeds crudities, heaviness of the head, falling away of the flesh, and leanness over all the body; and to conclude, it makes ulcers more dry, and so consequently rebellious, difficult to heal and malign. There are many other things may be spoken of sleep and watching, but these may suffice a Chirurgeon.

C H A P. XVII.

Of Repletion, and Inanition, or Emptiness.

The kinds of Repletions, or rather of Excesses.

Here are, to be short, two sorts of Repletion, or of all excess; one is of a simple quality, without any defluxion, or society of any humor, as appears in distempers without matter: the other is of quantity and mass, the body being distended with too much meat, or too great quantity of humors; from whence proceed an infinite number of diseases. They call the Repletion of meats, satiety or fulness; and it is of two kinds: The one which is called * Repletion or Fulness to the vessels; the other * Repletion to the strength.

*Re $\left\{ \begin{array}{l} \text{ad vasa} \\ \text{pletio} \end{array} \right. \text{advires}$

We judge of satiety to the vessels, by the distention and swelling of the veins and entrails, as the stomach. We call satiety to the strength, when the body is loaded with more meats than it can well bear. But also there is a double Repletion of humors. For either it is of some one humor, or of all the humors; they call this by a peculiar name, *Plethora*. For *Galen* defines *Plethora* an equal excess of all the humors. For it at any time he define a *Plethora* to be an excess of blood only; then verily by the name of blood, he understands an equal comprehension of the four humors; as it is taught in Physick schools.

Gal. Meth. 13. cap. 6.

What *Caco-chymia*.

The Repletion which is caused by some one humor, is termed by *Galen* in the place before mentioned, *Caco-chymia*, (that is, An evil juice) whether the Repletion proceed of a Choleric, Melancholic, Phlegmatick, or serous Humor.

The kinds of evacuation.

Now Inanition, or evacuation is no other thing than the expulsion or effusion of humors which are troublesome, either in quantity or quality. Of Evacuations, some are universal, which expell superfluous humors from the whole body; such are purging, vomiting, transpiration, sweats, Phlebotomy. Some particular, which are performed only to evacuate some part, as the brain by the nose, palat, eyes, ears; the lungs by the weazon; the stomach by vomit and stool; the guts by stool; the liver and the spleen by urine and ordure. These evacuations are sometimes performed by nature, freeing it self of that which is troublesome to it; otherwhiles by the Art of the Physitian in imitation of nature.

And again, one of these is good and requisite, when only the humor which is hurtfull either in quantity or quality, is evacuated; The other not requisite, or immoderate, when the profitable Humors, together with the unprofitable, are expelled.

The commodities of moderate scratching.

But what evacuations soever these be, they are performed and done, either by the scratching and rubbing of the skin, as when a Choleric, salt, or serous Humor, or some windiness lying between the skin and the flesh, cause itching. For by scratching the skin, it gets passage out, which is manifest by the efflux of a serous matter burning, or causing scabs and ulcers, if the humor be somewhat gross, but insensible and not so manifest, if it be windiness, the skin by that rubbing being rarified, and the gross flatulency attenuated. Wherefore they do ill who hinder their Patients from scratching, unless they scratch so cruelly and hard, that there may be danger (by reason of the great heat and pain thereby caused) of some defluxion or falling down of humors into the part.

The force of vomits:

Salivation.

The whole body is also purged by urine.

Or these evacuations are performed by much matter evacuated from an opened Bile, or running Ulcer, a Fistula, or such like sores. Or by sweats which are very good and healthfull, especially in sharp diseases, if they proceed from the whole body, and happen on the criticall days. By vomit, which often violently draws these humors from the whole body, even from the utmost joints, which purging medicins could not evacuate, as we may see in the Palsie, and Sciatica, or Hip-gout. By spitting, as in all who are suppurated either in the sides or lungs. By Salivation, or a Phlegmatick flux by the mouth, as in those who are troubled with the French-pox. By sneezing and blowing the nose; for by these, the brain oppress'd with moisture, disburdeneth its self, whether it be done without, or with the help of sternutatories and errhines; wherefore children, and such as have somewhat moist brains, purge themselves often this way. By hicket and belching; for by these the windiness contained in the stomach, is often expelled. By urine, for by this not only Feavers, but which is more to be admired, the French-pox hath often been terminated and cured.

For there have been some troubled with the Pox, in whom a flux of the vicious and venenate humor could not by Unctions of quicksilver be procured, either from the mouth or belly; yet have been wonderfully freed by abundance of urine, both from danger of death and their disease. By bleeding; for nature hath often found a way for grievous diseases, especially in young bodies, by bleeding at the nose, and by their courses in women. By a flux, or lask, purgation, sweats; insensible evacuation and transpiration; for so tumors, the matter being brought to suppuration, do sometimes vanish away and are dissolved, both of their own accord, as also by dissolving or discussing medicins. We do the same by exercise, diet, hot-houses, long sleep, waking, and shedding of tears. By sucking, as with cupping-glasses, and horse-leeches, in wounds made by venomous bitings.

In all such kinds of evacuations, we must consider three things, the quantity, quality, and manner of evacuation. As for an example, when an *Empyema* is opened, the matter which runs out, ought to be answerable in proportion to the purulent matter, which was contained in the capacity of the breasts; otherwise, unless all the matter be emptied, there may happen a relapse; the matter should be white, soft, equal, and nothing stinking: Lastly, you must let it forth not all together, and at one time, but by little and little, and at severall times, otherwise not a little quantity of the Spirits and heat doth flow out together, with the unprofitable matter, and so consequently a dissolution of all the powers.

We must observe three things in every evacuation.

CHAP. XVIII.

Of the Perturbations, or Passions of the minde.

The Perturbations are commonly called the Accidents of the minde, because as bodily accidents from the body, so may these be present and absent from the mind, without the corruption of the subject. The knowledg of these must not be lightly passed over by the Chirurgeon; for they stir up great troubles in the bodies, and yeeld occasion of many and great diseases; of which things, joy, hope, and love, may give an apparent testimony. For by these motions the heat and spirits are sometimes gently, sometimes violently diffused over all the body, for the enjoying of the present, or hoped for good. For then the heart is dilated, as to embrace the thing beloved, and the face is died with a rose and lively colour. For it is likely, that the faculty it self is stirred by the object, by whose power the heart it self is moved.

Why the Passions of the minde are called Accidents. Their force.

For it is first necessary, before we be moved by any Passions, that the senses in their proper seats, in which they are seldom deceived, apprehend the objects, and straight, as messengers carry them to the common sense, which sends their conceived forms to all the faculties. And then, that each faculty, as a Judge may afresh examin the whole matter, how it is, and conceive in the presented objects some shew of good, or ill; to be desired, or shunned. For what man that was well in his wits, did ever fall into a laughter, unless he formerly knew, or saw somewhat said or done, which might yeeld occasion of laughter? Therefore Joy proceeds from the heart, for the thing causing mirth or joy, being conceived, the faculty moves the heart, which shaken and moved by the faculty which hath dominion over it, is dilated and opened, as ready to embrace the exhilarating object. But in the mean time by the force of that dilatation, it sends forth much heat, and spirits together with the blood into all the body. A great part of which comming to the face, dilates it, the forehead is smooth and plain, the eies look bright, the cheeks become red, as died with Vermillion, the lips and mouth are drawn together, and made plain and smooth; some have their cheeks dented with two little pits (which from the effects are called laughing cheeks) because of the contraction or curling, which the muscles suffer by reason of their fulness of blood and spirits, all which to be brief is nothing but to laugh.

From whence they have their force.

The reason of Joy.

Joy recreates and quickens all the faculties, stirs up the spirits, helps concoction, makes the body to be better liking, and fattens it, the heat, blood, and spirits flowing thither, and the nourishing dew or moisture, watering and refreshing all the members; from whence it is, that of all the passions of the mind, this only is profitable, so that it exceed not measure; for immoderate and unaccustomed joy carries so violently the blood and spirits from the heart, into the habit of the body, that sodain and unlookt for death ensues, by a speedy decay of the strength, the lasting fountain of the vitall humour being exhausted. Which thing principally happens to those who are less hearty, as women and old men.

The effects of Joy.

Anger causeth the same effusion of heat in us, but far speedier than joy; therefore the spirits and humors are so enflamed by it, that it often causes putrid feavers, especially if the body abound with any ill humour.

Anger.

Sorrow, or grief dries the body by a way quite contrary to that of anger, because by this the heart is so strained, the heat being almost extinct, that the accustomed generation of spirits cannot be performed; and if any be generated, they cannot freely pass into the members with the blood; wherefore the vitall faculty is weakned, the lively colour of the face withers and decays, and the body wastes away with a lingering consumption.

Sorrow.

Fear in like sort draws in and calls back the spirits, and not by little and little as in sorrow, but sodainly and violently; hereupon the face growes sodainly pale, the extreme parts cold, all the body trembles or shakes, the belly in some is loosened, the voice as it were stays in the jawes, the heart beats with a violent pulsation, because it is almost opprest by the heat, strangled by the plenty of blood, and spirits abundantly rushing thither; The hair also stands upright, because the heat and blood are retired to the inner parts, and the utmost parts are more cold and drie than stone; by reason whereof the utmost skin and the pores, in which the roots of the hairs are fastned, are drawn together.

Fear.

Hippocr. lib. 4. de Merb.

Shame. Shame is a certain affection mixed, as it were, of Anger and Fear; therefore if, in that conflict of, as it were, contending passions, Fear prevail over Anger, the face waxeth pale, (the blood flying back to the heart;) and these or these Symptomes rise, according to the vehemency of the contracted and abated heat. But if on the contrary, Anger get the dominion over Fear, the blood runs violently to the face, the eyes look red, and sometimes they even foame at the mouth.

Shamefastness. There is another kind of shame, which the *Latins* call *Verecundia* (we Shamefastness) in which there is a certain flux, and reflux of the heat, and blood, first recoiling to the heart, then presently rebounding from thence again. But that motion is so gentle, that the heart thereby suffers no oppression, nor defect of spirits; wherefore no accidents worthy to be spoken of, arise from hence: this affect is familiar to young maids and boyes, who if they blush for a fault committed unawares, or through carelesness, it is thought an argument of a vertuous and good disposition.

An agony. But an agony, which is a mixt passion of a strong fear, and vehement anger, involves the heart in the danger of both motions; wherefore by this passion, the vitall facultie is brought into very great danger. To these six Passions of the mind, all other may be revoked, as Hatred and Discord, to Anger: Mirth and Boasting, to Joy; Terrors, Frights and Swoundings, to Fear; Envy, Despair and Mourning, to Sorrow.

By these it is evident, how much the passions of the mind can prevail, to alter and overthrow the state of the body; and that by no other means, than that by the compression and dilatation of the heart, they diffuse and contract the spirits blood, and heat; from whence happens the dissipation, or oppression of the spirits.

Why the first signs of passions of the mind appear in the face.

The signes of these Symptomes quickly shew themselves in the face; the heart, by reason of the thinness of the skin in that part, as it were painting forth the notes of its affections. And certainly the face is a part so fit to disclose all the affections of the inward parts, that by it you may manifestly know an old man from a young, a woman from a man, a temperate person from an untemperate, an *Ethiopian* from an *Indian*, a *Frenchman* from a *Spaniard*, a sad man from a merry, a sound from a sick, a living from a dead. Wherefore many affirm that the manners, and those things which we keep secret and hid in our hearts, may be understood by the face and countenance.

The use of passions of the mind.

Now we have declared what commodity and discommodity may redound to the man from these forementioned passions, and have shewed that anger is profitable to none, unless by chance to some dull by reason of idleness, or oppressed with some cold, clammy and phlegmatick humor; and fear convenient for none, unless peradventure for such as are brought into manifest and extream danger of their life by some extraordinary sweat, immoderate bleeding, or the like unbridled evacuation: Wherefore it behoves a wise Chirurgeon to have a care, lest he inconsiderately put any Patient committed to his charge into any of these passions, unless there be some necessity thereof, by reason of any of the forementioned occasions.

C H A P. X I X.

Of things against Nature, and first of the Cause of a disease.

What things against nature are.

What, and how many the causes of diseases be.

The primitive cause.

Internall antecedent.

Internall conjunct.

The congenit, or inevitable cause of death.

Having intreated of things naturall, and not naturall, now it remains we speak of things (which are called) against nature, because that they are such as are apt to weaken & corrupt the state of our body. And they be three in number; The cause of a disease, a Disease, and a Symptome. The cause of a disease is an affect against nature, which causes the disease. Which is divided into Internall and Externall. The Externall, originall or primitive comes from some other place, and outwardly into the body: such be meats of ill nourishment, and such weapons as hostilely wound the body.

The Internall have their essence and seat in the body, and are subdivided into antecedent and conjunct. That is called an antecedent cause, which as yet doth not actually make a disease, but goes near to cause one; so humors copiously flowing, or ready to flow into any part, are the antecedent causes of diseases; The conjunct is that which actually causes the disease, and is so immediately joyned in affinity to the disease, that the disease being present, it is present, and being absent, it is absent.

Again, of all such causes, some are born together with us, as the over-great quantity and malign quality of both the seeds, and the menstruous blood from diseased Parents are causes of many diseases, and specially of those which are called Hereditary.

Other happen to us after we be born, by our diet and manner of life, a stroke, fall or such other like. Those which be bred with us, cannot be wholly avoided or amended, but some of the other may be avoided, as a stroke and fall; some not, as those which necessarily enter into our body, as Air, Meat, Drink, and the like.

But if any will reckon up amongst the internal, inherent, and inevitable causes, the dayly, nay hourelly dissipation of the radical moisture, which the naturall heat continually preys upon;

upon; I do not gainsay it, no more than that division of Causes celebrated and received of Philosophers, divided into Materiall, Formall, Efficient, and Finall; for such a curious contemplation belongs not to a Chirurgeon, whom I only intend plainly to instruct. Wherefore that we have written may suffice him.

CHAP. XX.

Of a Disease.

Disease is an affect against Nature, principally, and by it self, hurting and depraving the action of the part in which it resides. The division of a Disease is threefold; Distemperature, ill Conformation, and the Solution of Continuity.

What a disease is, and how various.

Distemperature is a Disease of the similar parts dissenting, and changed from their proper and native temper. That digression from the native temper, happens two ways; either by a simple distemperature from the excess of one quality; and this is fourfold, Hot; Cold, Moist, and Dry; or by a compound distemperature, by the excess of two qualities, which also is fourfold; Hot and Moist, Hot and Dry; Cold and Moist, Cold and Dry. Again, every distemper is the fault of one simple and single quality, as an inflammation; or hath some vicious humors joined with it, as a Phlegmon: Again, a Distemperature is either equal, as in a *Sphacele*; or unequal, as in a *Phlegmon*, beginning or increasing.

A Distemperature.

Ill Conformity is a fault of the organicall parts, whose composition is thereby depraved. This hath four kinds; the first is, when the figure of the part is faulty, either by nature or accident, or some cavities abolished; as if a part which nature would have hollow for some certain use, do grow or close up: Or lastly, if they be rough, or smooth otherwise than they should, as if that part which should be rough, be smooth, or the contrary. Another is in the magnitude of the part increased, or diminished contrary to nature. The third is in the number of the parts increased or diminished; as if a hand have but four or else six fingers. The fourth is in the site and mutuall connexion of the parts; as if the parts which should be naturally united and continued be pluckt asunder, as happens in Luxations; or the contrary. The third generall kind of disease, is the solution of continuity, a Disease common, both to the similar and organicall parts, acquiring diversity of names, according to the variety of the parts in which it resides.

Ill Conformity.

Solution of Continuity.

CHAP. XXI.

Of a Symptome.

Do not in this place take the word Symptome in the most generall acceptation, for every change or accident which happens to man besides his own nature; but more reservedly and specially, only for that change which the disease brings, and which follows the disease, as a shadow doth the body.

What a Symptome is.

There be three kindes of a Symptome properly taken. The first is, when the action is hurt; I say hurt, because it is either abolished, weakned, or depraved; so blindness is a deprivation or abolishing of the action of seeing; dulness of sight, is a diminution or weakning thereof; and a suffusion, such as happens at the beginning of a Cataract, when they think flies, hares, and such like bodies fly to and fro before their eyes, is a depravation of the sight.

Three kindes thereof.

The second is a simple affect of the body, and a full fault of the habit thereof being changed, happening by the mutation of some qualities: such is the changing of the native colour into a red by a Phlegmon, and into a livid and black by a Gangrene; such is the filthy stench the nose affected with a *Polypus* sends forth; the bitter taste, in such as have the Jaundise; and the rough and rugged skin in them which are Leprous.

The third is the fault of the overmuch retention of excrements which should be expelled, and expulsion of such as should be retained; for the evacuation of an humor profitable both in quantity and quality, is against nature, as bleeding in a body not full of ill Humors, nor Plethorick; and also the retention of things hurtfull in substance, quantity and quality, as the Courses in women, the urine, and the stone in the bladder.

CHAP. XXII.

of Indications.

What Indication is.

The knowledg and exercise of Indications befits that Chirurgion, whom no blind rashness of fortune, but reason; no chance, but counsell directs in the undertaking and performing the works of his Art. For an Indication is a certain safe and short way, which leads the Physitian, as by the hand, to the attainment of his purposed end, of preserving the sound, or curing the sick.

See Method, Cap. 7. Lib. de opt. secta, Cap. 11.

For Galen doth define an Indication to be a certain insinuation of what is to be done, or a quick and judicious apprehension of that which may profit or hurt. And as Faulconers, Mariners, Plowmen, Souldiers, and all manner of Artizens, have their peculiar terms and words, which are neither known, nor used by the vulgar; so this word Indication is proper and peculiar to Physitians and Chirurgions, as a Term of Art not vulgar; by consideration of which, as by some sign, or secret token, they are admonished what is to be done to restore health, or repell an imminent danger.

The kinds of Indications.

There are three prime and principall kinds of Indications, every of which is subdivided into many other. The first is from things naturall. The second from those things which are termed not naturall. The third from those things which are contrary to nature. Things naturall shew they must be preserved by their like, and in the compass of these are contained all the Indications which are drawn from the nature of the Patient, that is, from his strength, temper, age, sex, habit, custome, diet.

Lib. 9. Method. cap. 9.

Things not naturall may be doubted as uncertain, for one while they indicate the same things with things naturall, that is, they coindicate with the strength, temper and the rest; otherwhiles they consent with things against nature, that is, they coindicate with the disease. Wherefore Galen when he saith, that Indications are drawn from three things; The disease, the nature of the Patient, and the encompassing air; by proposing the familiar example of the air, he would have us to understand the other things not naturall; because we may shun or imbrace them more or less as we will our selves, but we must, whether we will or no, endure the present state of the air. Therefore the air indicates something to us, or rather coindicates; for if it nourish the disease, as conspiring with it, it will indicate the same that the disease, that is, that it must be preserved in the same state.

Indications drawn from things naturall.

Things contrary to nature indicate they must be taken away by their contraries; therefore that we may more accurately and fully handle all the Indications drawn from things naturall, we must note, that some of these are concerning the strength of the Patient, by care to preserve which, we are often compelled for a time to forsake the cure of the proper disease: for so a great shaking happening at the beginning of an ague or fever, we are often forced to give sustenance to the Patient, to strengthen the powers shaken by the vehemency of the shaking, which thing notwithstanding lengthens both the generall and particular fits of the ague. Other pertain to the temper, other respect the habit, if the Patient be slender, if fat, if well flesht, if of a rare, or dense constitution of body. Other respect the condition of the part affected in substance, consistence, softness, hardness, quick or dull sense, form, figure, magnitude, site, connexion, principality, service, function and use. From all these, as from notes, the skilfull Chirurgion will draw Indications according to the time and part affected: for the same things are not fit for fore eyes, which were convenient for the ears, neither doth the phlegmon in the jaws and throat admit the same form of cure, as it doth in other parts of the body. For none can there outwardly apply repercussives, without present danger of suffocation. So there is no use of repercussives in defluxions of those parts which in site are neer the principall. Neither must thou cure a wounded Nerve and Muscle, after one manner. The temperature of a part, as Moisture, alwayes indicates its preservation, although the disease be moist, and give Indication of drying, as an ulcer. The principality of a part alwayes insinuates an Indication of astringent things, although the disease require dissolving, as an Obstruction of the Liver; for otherwise unless you mix astringent things with dissolving, you will so dissolve the strength of the part, that hereafter it cannot suffice for sanguification. If the texture of a part be rare, it shews it is less apt, or prone to obstruction; if dense, it is more obnoxious to that disease, hence it is that the Liver is oftener obstructed than the Spleen. If the part be situate more deep, or remote, it indicates the medicines must be more vigorous and liquid, that they may send their force so far. The sensibleness, or quick-sense of the part, gives Indication of milder medicines, than peradventure the signs, or notes of a great disease require. For the Physitian which applies things equally sharp to the Horny tunicle of the eye being ulcerated, and to the Leg, must need be counted either cruell, or ignorant. Each sex and Age hath its Indications, for some diseases are curable in youth, which we must not hope to cure in old age; for hoariness and great distillations in very old men, admit no digestion, as Hippocrates saith.

What the conditions of the parts affected do indicate.

Indications from the ages.

Atbor. 40. li. 2.

Nunquam decrepitis Branchum coquit, atque Coryzam.

The feeble Sire, for age that hardly goes,
Ne're well digests the hurtfull Rheume or pose.

Moreover according to his decree the diseases of the Reins, and whatsoever pains molest the bladder, are difficultly healed in old men; and also reason persuades that a Quartain admits no cure in Winter, and scarce a Quotidian; and ulcers in like manner are more hard to heal in Winter; that hence we may understand certain Indications to be drawn from times, and to increase the credit of the variety and certainty of Indications, some certaine time, and seasons in those times command us to make choise of medicines; for as *Hippocrates*

Aphor 6 sect. 6.

Aphor 5 sect. 4.

Ad Canis ardorem facilis purgatio non est.
In Dogdayes heat it is not good,
By purging for to cleanse the blood.

Neither shalt thou so well prescribe a slender diet in Winter, as in the Spring, for the air hath its Indications. For experience teaches us, that wounds of the head are far more difficultly and hardly cured, at *Rome, Naples, and Rochell* in *Xantoigne*. But the times of diseases yeeld the principall Indications, for some Medicines are only to be used at the beginning and end of diseases, others at the increase and vigour of the disease. Wee must not contemn those Indications which are drawn from the vocation of life, and manner of Diet; for you must otherwise deal with the painfull Husbandman (when he is your Patient) which leads his life sparingly and hardly, than with the Citizen who lives daintily and idly. To this manner of life and Diet may be referred a certain secret and occult property, by which many are not only ready to vomit at eating of some meats, but tremble over all their bodies when they hear them but spoken of. I knew a prime Nobleman of the *French Nobility*, who was so perplexed at the serving in of an Eel to the Table, at the midst of dinner and amongst his friends, that he fell into a swoond, all his powers failing him. *Galen* in his book *de Consuetudine* tells that *Arius* the *Peripatetick* died sodainly, because compelled by the advice of those Physicians he used, he drank a great draught of cold water in the intolerable heat of a Fever. For no reason, saith *Galen*, than that, because he knowing he had naturally a cold stomach from his childhood, perpetually abstained from cold water.

From our diet.

Haite arising from secret properties.

For as much as belongs to Indications taken from things against nature; the length and depth of a wound or ulcer indicates one way; the figure cornered, round, equall and smooth; unequall and rough, with a hollownes freight or winding, indicate otherwise; the site right, left, upper, lower in another manner, and otherwise the force and violence of antecedent and conjunct causes. For oftentimes the condition of the cause indicates contrary to the disease, as when abundance of cold and gross humors cause and nourish a Fever. So also a Symptome often indicates contrary to the disease, in which contradiction, that Indication must be most esteemed, which doth most urge; as for example sake, if swoounding happen in a Fever, the feverish burning shall not hinder us from giving wine to the Patient.

Indications taken from things against nature.

Wherefore these Indications are the principallest and most noble which lead us, as by the hand, to doe these things which pertain to the cure, prevention and mitigating of diseases. But if any object, that so curious a search of so many Indications is to no purpose, because there are many Chirurgeons, which setting only one before their eyes, which is drawn from the Essence of the disease, have the report and fame of skilfull Chirurgeons, in the opinion of the vulgar; But let him know that it doth not therefore follow, that this indication is sufficient for the cure of all diseases; for we do not alwayes follow that which the Essence of the disease doth indicate to be done. But chiefly then, where none of the fore-recited Indications doth resist or gainsay; you may understand this by the example of a *Plethora*, which by the Indication drawn from the Essence of the thing requires Phlebotomy; yet who is it, that will draw blood from a child of three months old? Besides, such an Indication is not artificiall but common to the Chirurgeon with the common people. For who is it that is ignorant, that contraries are the remedies of contraries? and that broken bones must be united by joyning them together? but how it must be performed and done, this is of Art and peculiar to a Chirurgeon, and not known to the vulgar. Which the Indications drawn from those fountains we pointed at before, abundantly teaches, which, as by certain limits of circumstances, encompass the Indication which is taken from the Essence of the disease, lest any should think, we must trust to that only. For there is some great and principall matter in it, but not all. For so the meanest of the common people is not ignorant, that the solution of continuity is to be cured by repairing that which is lost. But in what parts we may hope for restitution of the lost substance, and in which not, is the part of a skilfull Chirurgeon to know and pronounce. Wherefore he will not vainly bestow his labour

We do not alwayes follow the Indication which is from the disease.

In what parts we cannot hope for restoring of solution of continuity

labour

labor to cure the nervous part of the *Diaphragma*, or Midriff being wounded, or the Heart, small Guts, Lungs, Liver, Stomach, Brain or Bladder; and that I may speak in a word, Empiricks are not much more skilfull than the common people, although they do so much extoll themselves above others by the name of experience. For although experience be another instrument to find out things with reason, yet without reason, it will never teach what the substance of the part in which the disease lies, may be; or what the action, use, site, connexion, from whence speciall and proper Indications are drawn; With which the Chirurgeon being provided and instructed shall not only know by what means to find out a remedy, but also, lest he may seem to mock any with vain promises, he shall discern what diseases are incurable, and therefore not to be medled withall.

But implicit or intricate diseases require each to be cured in their severall order, except some one of them be desperate, or so urge & press that the Physitian think it necessary after preposterous order, to begin with it, although often he be forced to make some one of these diseases incurable, or give occasion of causing some new one: into which straits we are necessarily compelled to fall, when, (for example) we determine to pull, or take away some extraneous body; for the performance whereof we are compelled to enlarge the wound. So we are forced by necessity to open the neck of the bladder, (that so we may draw forth the stone therein contained) with a wound which often degenerates into an incurable Fistula. For that disease which threatens danger of present death is of such moment, that to shun that it may be counted a small matter, and commodious for the sick to bring in other diseases, though incurable. For if a convulsion happen by pricking a Nerve, which we cannot heal by any remedies, then by cutting the Nerve asunder we end the convulsion, but deprive the part into which that Nerve did goe, of the use of some voluntary motion. So if in any great joynt there happen a Luxation with a wound, because there is danger of convulsion by trying to restore and set right the luxated part, we are forc'd for shunning thereof, to attend the wound only, and in the mean time to let alone the Luxation. Otherwise in implicit diseases if there be nothing which may urge, or call us from the ordinary cure, we must observe this order, that beginning with that affect, which hinders the cure of the principall disease, we prosecute the rest in the same and their proper order, untill all the diseases being overcome we shall restore the part affected to its integrity. Therefore let us take for an example, an ulcer in the Leg, a *Varix* (or big swollen vein) and a Phlegmonous tumor round about it; and lastly; a body wholly plethorick and filled with ill humors; order and reason require this, that using the advise of some learned Physitian we prescribe a convenient diet, and by what means we may, bring him to an equality by purging and blood-letting, and then we will scarifie in divers places the part where it is most swollen, then presently apply Leeches, that so we may free it from the burden of the conjunct matter; then use Cauteries to help the corruption of the bone, and in the mean time change the circular figure of the ulcer into an ovall, or triangular; then at the length we will undertake the cutting of the *Varix*, and cure the ulcer which remains according to Art, and so at the length cicatrize it. In all this whole time the Patient shall neither walk, nor stand, nor sit, but ly quietly, having his Leg orderly and decently rowled up. But if (as it often happens) the temper of the hurt part, be different from the temper of the whole body, the manner of curing must be so tempered, that we increase the dosis of hot or cold medicines, according to the ratable proportion of the indications requiring this or that, therefore imagine the part ulcerated to be such, as that it is two degrees dryer than the just temper; but the whole body to exceed the same temper in one degree of humidity: reason and Art will require, that the medicin applyed to the ulcer be dryer by one degree than that which the part would otherwise require if it were temperate; but on the contrary let us suppose thus: the whole body to be one degree more moist then the temper requires, and the ulcerated part to be one degree dryer: truly in this case the medicine that is applyed to the ulcer by reason of the part it self, shall not be increased in dryness, but wholly composed and tempered to the Indication of the ulcer, because the force of the moisture exceeding in the like degree, doth counterpoise the superfluous degree of dryness. But it is more easie by an artificiall conjecture to determine of all such things, than by any rules or precepts.

To these so many and various Indications, I think good to add two other; the one from similitude; the other of a certain crafty devise, & as the latter Physitians term it, of a certain subtil stratagem. We draw Indication from similitude, in diseases which newly spring up and arise, as which cannot be cured by Indications drawn from their contraries, as long as their Essence is unknown and hid; wherefore they think it necessary to cure them by a way and Art like those diseases, with which they seem to have an agreeing similitude of Symptoms and Accidents; Our Ancestors did the same in curing the French Pocks, at the first beginning thereof, as long as they assimilated the cure to that of the Leprosie, by reason of that affinity, which both the diseases seem to have. But we follow crafty devices and subtil counsels, when the Essence of the disease we meet, with is wholly secret and hid, either because it is altogether of a hidden and secret nature, and which cannot be unfolded by manifest qualities, or else resides in a subject which is not sufficiently known to us, nor of a physicall contemplation, as the Mind. For then we being destitute of Indications taken

from

Experience without reason is like a blind man without a guide.

Indications in implicit diseases.

An example of Indications in implicit diseases.

What we must do when the temper of the part is different from the temper of the whole body.

An artificiall conjecture is of much force in Indications.

Indication from similitude.

Indication of a subtil device.

from the nature of the thing, are compelled to turn our cogitations to impostures and crafty counsels; and they say this Art and Craft is of chief use in Melancholy affects and fictions, which are often more monstrous and deformed than the *Chimera* so much mentioned in the fables of the Ancients; to which purpose, I will not think much to recite two Examples. A certain man troubled with a Melancholick disease, I know not by what error of opinion, had strongly perswaded himself that he was without a head; the Physicians omitted nothing, by which they might hope to take this mad opinion out of his mind. But when they had in vain tryed all medicines, at length they devised this crafty, but profitable device; they fastened and put upon his head a most heavy helmet, that so by the pain and trouble of his head nodding and drawn down by that weight, he might be admonished of his error.

Examples.

It is reported, another molested by the obscurity and darkness of the same disease, did verily beleve, that he had horns upon his head; neither could he be drawn or diverted from that absurd and monstrous opinion, untill that binding up his eyes, they miserably bruised and scratched his forehead with the bony roughness of the lower parts of an oxes horns, that so he begun to believe by the painfull drawing of the blood that ran down his face, that those bloody horns were forcibly plucked from him. Ingenious Chirurgeons in imitation of these examples may in like cases do the like. For that case requires a man of a quick apprehension and advice, who may give manifest proof of his diligence and skill by medicinall stratagems, as who forthwith can politickly devise stratagems of divers sorts.

A Physician should be of a quick apprehension.

But, now coming to the end of this our tract of Indications, we must chiefly and principally observe; That of Indications some are Indicative; which absolutely and of themselves command this to be done; other conidicative, which indicate the same with the Indicative, and joyntly shew it to be done, but in some sort secundarily and not primitively; some are repugnant, which of themselves and their own nature perswade quite contrary to that the indicative primitively did perswade us; other correpugnant, which give their voice after the same form and manner with the repugnant against the indicative, as the coindicative consent to and maintain them. Let this serve for an example of them all.

Indications indicative. Coindicative.

A *Plethora*, or plenitude of humors of its own nature, requires and indicates blood-letting, the Spring time perswades and coIndicates the same, but to this counsell is quite opposite and repugnant, a weak faculty, and childhood is correpugnant.

Repugnant. Correpugnant.

Wherefore these four must be diligently weighed and considered when we deliberate what is to be done, and we must rather follow that which the indicative, or repugnant shew and declare, as what the diseases and strength of the Patient require, than that which the coindicative, or correpugnant shall perswade, because they have a weaker and but secundary power of indicating, and not essentiall & primitive. But because the kinds of Indications are so many and divers, therefore that the knowledg of them may be more perspicuous and less confused, I have thought good to describe and distinguish them by this following scheme.

A

A Table of Indications.

From the strength and faculties of the patient. } For whose preservation, oftentimes the proper cure of the disease must be neglected; for where these fail, it is impossible the Chirurgion should perform what he desires and expects.

From the temperament, as if the Patient shall be } Sanguine, } Of preservation of which the Chirurgion must have care, and if they swerve from equality, to reduce them to that which formerly they naturally were.
 Choleric,
 Flegmatick,
 Melancholick.

From the habit of the body, as the patient shall be } Dainty and delicate,
 Slender and weak,
 Low of stature,
 Rare, or else dense and compact.

From the native condition of the humors or affected part, in which we consider, either } The substance thereof, as for as much as it is similar, we consider whether it be hot, cold, moist, dry, or as it is organically, and then whether it be a principall and noble part, or a subordinate and ignoble part.
 Or the sense, whether quick, or dull, by reason whereof the eye cannot endure such sharpe and acrid medicines, as simple flesh can.
 Or the form, figure, magnitude, number, site, connexion, use.

From the Age, for each age yeelds his peculiar Indications, hence you may observe most diseases to be incurable in old men, which are easily cured in young, others which in youth admit of no cure, unless by the change of age and the ensuing temperament.

From Sex, for medicines work upon women far more easily than upon men.

From the time of the year, for some meats and medicines are fit in Winter, some in Summer.

From the Region, for as there are diversities of situations and habits of places, so also there are motions of humors, and manners of diseases: hence it is that wounds on the head at Paris, and sore shins at Avignon are more difficult to be cured.

From the times of diseases, for some things in the beginning, others in the increase, state and declining of the disease, are more convenient.

From the manner of diet, for this, as the proper temper, must be preserved. Wherefore such must be fed otherwise who live daintily, than those who lead their lives sparingly and hardly. Hereunto add certain peculiar natures, which by a certain hidden property are offended at this, or that kind of meat. For there are some which not onely cannot conceit Pissan, Apples, Soles, Partridge, Water and sush like, but can scarce behold them without nauseousness.

The first is drawn from things naturall which indicate their preservation by their like; of this kind are many other which are drawn, either

An Indication is a certain plain and compendious way which leads the Chirurgion to a certain, determinate and proposed end for the cure of the present disease; of which there are three kinds.

The second is drawn from things not naturall, which one while indicate their preservation by their like, another while their change by their contraries; for so

If the Air, have as it were conspired with the disease by a certain similitude of qualities to the destruction of the Patient, it must be corrected by its contraries, according to Art.
 But if by the disagreement of qualities it resist the disease, it must be kept in the same temper.

The third from things contrary to nature, which shew, they must be taken away by the use of their contraries, as

The disease, the Indication being drawn from these,

The greatness The complication or commixtion with other; so

In implicit, or mixed diseases we may draw Indications from these three heads;

From that which is most urgent
 From the cause
 and
 From that, without which the disease cannot be taken away;

such are

Bitterness of pain, a defluxion into a part, a Varix, or big swollen vein, a distemperature, if they be joined with a disease.

Cause of the disease }
 Symptome }

which two often indicate and require medicines contrary to the disease.

CHAP. XXIII.

of certain wonderfull and extravagant ways of curing Diseases.

Monsters sometimes happen in nature, so also in diseases, and in the events and cures of diseases. I understand by monsters certain marvailous successes in diseases, or certain ways of curing them, which swerve from Art, and happen besides reason, nature, and common use.

Monstrous diseases.

Alexander ab Alexandro, and Peter Gilius tell, that in Apulia a part of Italy they have a certain kind of Spider very frequent; the natives call it *Tarantula*, Petrus Rhodius calls it *Phalangium*; The Inhabitants find these Spiders in the first heat of Summer so venenate and deadly, that whomsoever they touch with their virulent biting, he presently, without he have speedy remedy, deprived of all sense and motion falls down, or certainly if he escape the danger of death, he leads the remnant of his life in madness. Experience hath found a remedy by Musick for this so speedy and deadly a disease: Wherefore as soon as they can they fetch Fiddlers and Pipers of divers kinds, who by playing and piping may make musick; at the hearing whereof, he which was fallen down by reason of the venomous bite, rises cheerfully, and dances so long to their measures and tunes, untill by the painfull and continued shaking and agitation of the whole body, all the malignity is dissipated by transpiration and sweats.

The wonderfull force of the bite of a certain Spider.

Musick the remedy thereof.

Alexander adds, that it happened once in his sight, that the Musicians their wind and hands failing them ceased playing, and then the Dancer presently fell down as if he had been dead; but by and by the Musick beginning anew, he rose up again and continued his dancing till the perfect dissipation of the venome. And that it hath happened besides, that one not so perfectly healed, certain reliques of the disease yet remaining, when a long time after he heard by chance a noise of Musicians, he presently fell a leaping and dancing, neither could he be made to leave before he was perfectly cured.

Some affirm according to the opinion of *Asclepiades*, that such as are frantick are much helped with a sweet and muscical harmony. *Theophrastus* and *Aulus Gellius* say, that the pain of the Gout and Sciatica are taken away by Musick. And the sacred Scripture testifies, that *David* was wont by the sweet sound of the Harp to refresh and ease king *Saul* when he was miserably tormented by his evil spirit. *Herodotus* in *Clio* tells, that *Cræsus* the king of *Lydia* had a Son, which of a long time could not speak, and when he came to mans estate was accounted dumb: but when an enemy with his drawn sword invaded his father (overcome in a great fight, and the City being taken in which he was) not knowing that he was the King, the young man opened his mouth endeavouring to cry out, and with that striving and forcing of the Spirit, he broke the bonds and hinderances of his tongue, and spoke plainly and articulately, crying out to the enemy that he should not kill King *Cræsus*. So both the enemy with-held his sword, and the king had his life, and his son had his speech always after. *Plutarch* in his book, Of the benefit to be received from our enemies, tells, That a *Thessalian* called *Proteus*, had a certain inveterate and incurable Ulcer in a certain part of his body, which could not be healed, before he received a wound in a conflict in the same place, and by that means the cure being begun afresh, the wound and ulcer were both healed.

Musick gives ease to pain.

A strong perturbation of the mind helps by moving the spirits.

Quintus Fabius Maximus, as *Livie* writes, was long and very sick of a quartain Ague, neither could have wished success from medicins administered according to Art, untill skirmishing with the *Allobroges*, he shook off his old feverish heat, by a new heat and ardent desire of fighting. It was credibly reported to me of late by a Gentleman of the Lord of *Lansackes* Chamber, that there was a French Gentleman in *Polonia*, who was grievously tormented with a quartain Fever, who on a time walking upon the bank of the river *Wisell*, to take away the irksomness of his fit, was thrust in jest into the River by a friend of his that met him by chance, by which (although he could swim, as he also knew that thrust him in) he conceived so great fear, that the Quartain never troubled him after. King *Henry* the second commanded me to go from the Camp at *Amiens* to the City *Dórlan*, that I might cure those that were hurt in the conflict with the Spaniards, the Captain *S. Arbin*, although at that time he had a fit of a Quartain ague, yet would he be present at the fight, in which being shot through the side of his neck with a Bullet, he was stricken with such a terror of death, that the heat of the Fever was asswaged by the cold fear, and he afterwards lived freed from his Ague.

Chance sometimes exceeds Art.

Franciscus Valeriola the famous Physitian of *Arles*, tells, That *John Berlam* his fellow Citizen troubled with a Palsey of one side of his body for many years, his house taking fire, and the flame coming near the bed in which he lay, he stricken with a great fear, suddenly raised himself with all the force he had, and presently recovering the strength of his body, leaps out at the window from the top of the house, and was presently

Observ. 4. lib. 2.

cured of his disease, sense and motion being restored to the part, so that afterward he went upright without any sense of pain, who lay unmovable for many yeers before. He tells the like in the same place of his cousin *John Soliratus*; hee was a long time lame at *Avignon*, by reason that the Nerves of his hams were shrunk and drawn up, so that he could not go; being moved with a vehement and sodain passion of anger against one of his servants whom hee endeavoured to beat, he so stirred his body that forthwith the Nerves of his hams being distended and his knees made pliant he began to go and stand upright without any sense of pain, when he had been crooked about the space of six yeers before, and all his life after he remained sound.

Cap ult. lib. de
cur. rat per san-
guinis miss.

Galen by a
dream cures
the Sciatica.

Galen tells he was once fetched to stanch the bleeding, for one who had an Artery cut neer his Anckle, and that by his means he was cured without any danger of an *Aneurisma* (i) a relaxation of a veinous vessell; and besides by that accidentall wound he was freed from most grievous pain of his hip, with which he was tormented four yeers before: but although this easing of the pain of the Sciatica happened according to reason by the evacuation of the conjunct matter, by the artery of the anckle of the same side being opened; yet because it was not cut for this purpose, but happened only by chance, I judged it was not much dissenting from this argument.

Pliny writes that there was one named *Phalereus*, which casting up blood at his mouth, and at the length medicines nothing availing, being weary of his life, went unarmed in the front of the battell against the enemy, and there receiving a wound in his breast, shed a great quantity of blood, which gave an end to his spitting of blood, the wound being healed, and the vein which could not contain the blood being condensate.

At *Paris*, Anno 1572. in *July*, a certain Gentleman being of a modest and curteous carriage fell into a continuall Fever, and by that means became Frantick, moved with the violence of which he cast himself headlong out of a window two stories high, and fell first upon the shoulder of *Valterra* the Duke of *Alenzons* Physitian, and then upon the pavement; with which fall he cruelly bruised his ribs and hip, but was restored to his former judgment and reason. There were present with the Patient besides *Valterra*, witnesses of this accident these Physitians, *Alexis*, *Magnus*, *Duretus*, and *Martinus*. The same happened in the like disease, and by the like chance to a certain *Gascoyn* lying at the house of *Agrippa* in the *Pa-ved* street.

Othomannus Doctor of Physick of *Mompelier* and the Kings Professor, told me that a certain Carpenter at *Broquer* a village in *Switzerland*, being frantick cast himself headlong out of an high window into a river, and being taken out of the water was presently restored to his understanding.

The cause of
the last recited
cures.

But if we may convert casualties into counsel and Art, I would not cast the Patient headlong out of a window. But would rather cast them sodainly and thinking of no such thing into a great cistern filled with cold water, with their heads foremost, neither would I take them out untill they had drunk a good quantity of water, that by that sodain fall and strong fear, the matter causing the Frenzy might be carryed from above downwards, from the noble parts to the ignoble; the possibility of which is manifest by the forecited examples, as also by the example of such as bit by a mad Dog, fearing the water are often ducked into it to cure them.

CHAP. XXIV.

Of certain juggling and deceitfull wayes of Curing.

Here I determine to treat of those Impostors, who taking upon them the person of a Chirurgeon, do by any means either right or wrong, put themselves upon the works of the Art; but they principally boast themselves amongst the ignorant common sort, of setting bones which are out of joint and broken, affirming as falsely as impudently, that they have the knowledg of those things from their Ancestors; as by a certain hereditary right; which is a most ridiculous fiction; for our minds when we are born, is as a smooth table, upon which nothing is painted. Otherwise what need we take such labour and pains to acquire and exercise sciences? God hath endued all brute beasts with an inbred knowledg of certain things necessary for to preserve their life, more than man.

Sciences are
not hereditary.

But on the contrary he hath enriched him with a wit furnished with incredible celerity and judgment, by whose diligent and laborious agitation he subjects all things to his knowledg. For it is no more likely, that any man should have skill in Chirurgery because his father was a Chirurgeon, than that one who never endured sweat, dust nor Sun in the field, should know how to ride and govern a great horse, and know how to carry

carry away the credit in tilting, only because he was begot by a Gentleman and one famous in the Art of War.

There is another sort of Impostors far more pernicious and less sufferable, boldly and insolently promising to restore to their proper unity and seat, bones which are broken and out of joint, by the only murmuring of some conceited charms, so that they may but have the Patients name and his girdle. In which thing I cannot sufficiently admire the idleness of our Country-men so easily crediting so great and pernicious an error; not observing the inviolable law of the ancient Physitians, and principally of Divine *Hippocrates*, by which it is determined, that three things are necessary to the setting of bones dislocated and out of joynt; to draw the bones asunder; to hold the bone receiving, firmly immoveable with a strong and steady hand; to put the bone to be received into the cavity of the receiving. For which purpose the diligence of the Ancients hath invented so many engines, Glossocomies and Bands, lest that the hand should not be sufficient for that laborious work. What therefore is the madness of such Impostors to undertake to do that by words, which can scarce be done by the strong hands of so many Servants, and by many artificial engines?

A most impudent sort of Impostors.

Three things necessary for the cure of a Luxation.

Of late years another kind of Imposture hath sprung up in *Germany*, they beat into fine powder a stone which in their mother tongue they call *Bembruch*, and give it in drink to any who have a bone broken, or dislocated, and affirm that it is sufficient to cure them. Through the same *Germany* there wander other Impostors who bid to bring to them the Weapons with which any is hurt; they lay up in a secret place and free from noise, and put and apply medicines to it, as if they had the patient to dress, and in the mean time they suffer him to go about his business, and impudently affirm that the wound heals by little and little by reason of the medicine applyed to the weapon.

But it is not likely that a thing inanimate which is destitute of all manner of sense, should feel the effect of any medicine; and less probable by much, that the wounded party should receive any benefit from thence. Neither if any should let me see the truth of such juggling by the events themselves and my own eyes, would I therefore believe that it were done naturally and by reason, but rather by charms and Magick.

In the last assault of the Castle of *Hisdin* the Lord of *Martigues* the elder was shot through the breast with a Musket bullet. I had him in cure together with the Physitians, and Chirurgeons of the Emperour *Charles* the sixth and *Emanuel Philibert* the Duke of Savoy, who because he entirely loved the wounded prisoner, caused an assembly of Physitians and Chirurgeons to consult of the best means for his cure. They all were of one opinion, that the wound was deadly and incurable, because it passed through the midst of his lungs, and besides had cast forth a great quantity of knotted blood into the hollownes of his breast.

There was found at that time a certain *Spaniard*, a notable Knave, and one of those Impostors, who would pawn his life, that he would make him sound; wherefore this Honorable Personage being in this desperate case was committed unto his care. First of all hee bid they should give him the Patients shirt, which he tore into shreds and peeces, which presently framing into a Cross, he laid upon the wounds whispering some conceived or coined words, with a low murmure. For all other things he wished the Patient to rest content, and to use what diet he pleased, for he would do that for him, which truly he did. For he eat nothing but a few prunes, and drunk nothing but small beer, yet for all this the wounded Prince died within two days; the *Spaniard* slipt away, and so scaped hanging. And whilest I opened the body in the sight of the Physitians and Chirurgeons to embalm him, the signs and accidents of the wound did evidently and plainly appear to be as we had pronounced before.

And there be also other Jugling companions of this tribe, who promise to cure all wounds with lint, or Tents, either dry, or macerated in oyl or water, and bound to the wound, having murmured over some charm or other, who have had sometimes good success, as I can witness. But the wounds upon which tryall was made were simple ones, which only required union, or closing for to perfect the cure. So verily the bones of beasts when they be broke, grow together by the only benefit of nature. But when the affect shall be compound by diversity of Symptomies, as a wound with an ulcer, inflammation, contusion and fracture of a bone, you must hope for no other from Tents or Lints, nor charms than death. Therefore the common sort who commit themselves to these Impostors to be cured do not only injure themselves, but also hurt the Common-wealth, and the common profit of the Citizens; for whose good and justice sake a prudent Magistrate ought to deprive Impostors of all freedome in a free and Christian common-wealth.

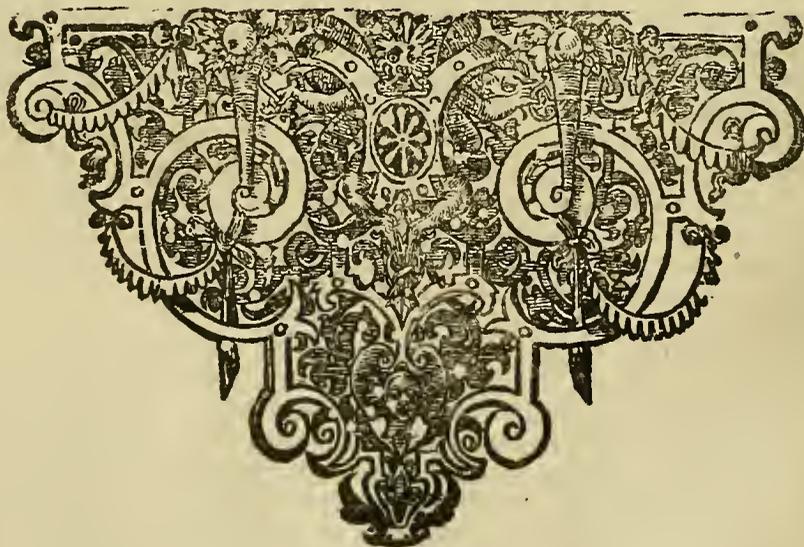

What wounds may be cured only by lint, or by tents and Water.

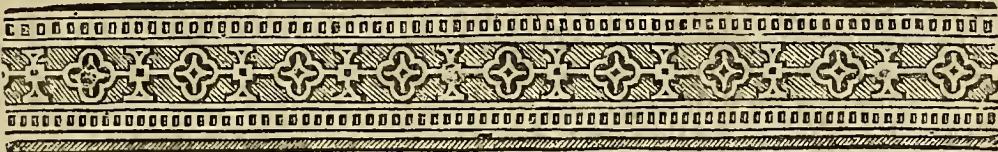

Witches, Conjurers, Diviners, Soothsayers, Magicians, and such like, boast of curing many diseases; but if they do or perform any thing in this kind, they do it all by sleights, subtilties and forbidden Arts, as Charms, Conjurations, Witcheries, Characters, Knots, Magickall Ligatures, Rings, Images, Poysons, laces tyed across, and other damnable tricks, with which they pollute, pervert and defame the prime and sacred Art of

Deut. 18.

Physick, and that with the danger of mens lives. Who certainly are to be banished by the laws of our Countrey, especially seeing it is decreed in *Moses* law, *Let none be found among you that useth witchcraft, or a regarder of times, or a marker of the flying of Fowls, or a Sorcerer, or a Charmer, or that counselleth with Spirits, or a Soothsayer, or that asketh counsell at the dead; for all that do such things, are abomination to the Lord, and because of these abominations the Lord thy God doth cast them out before thee.* But the Miracles of our Lord *Jesus Christ* the Son of God, and of his Saints and Apostles in curing diseases beyond nature and all Art, are of another kind, which we ought to beleve so firmly and constantly, that it should be counted an impiety for a Christian to doubt of them. All holy Writings are full of these; as to give sight to the blinde, hearing to the deaf, power to go to those sick of the Palfie, to drive forth Devils, to cure the Leprosie, to give fruitfulness to women, to raise the Dead, and perform by the holy Ghost other Miracles which exceed the condition and law of Nature; whom here we earnestly intreat to free and protect us from unclean Devils, and the spirits of diabolicall deceit, and to give us the mind that we may will and be able always to aspire to Heaven, and fasten the hope, safety, and anchor of all our fortunes in God alone. *Amen.*

The End of the first Book.

The second Book, O F LIVING CREATURES,

And of the Excellency of

M A N.

Efore I come to speak of the Anatomy of Mans body, I have thought fit to say a little of the nature of brute Beasts. There is between Beasts a great deal of difference by nature; for of these, some are hardy and bold, others fearfull; some wilde and savage, others tame; some walking in herds, others wandring alone; some covered and defended with shels and scales, as the Crocodile, the Tortois, and many kinds of fish; others have stings and prickles.

The difference
of brute beasts.

The Horse hath his hard and strong hoofs, his crest (as being a generous beast) beset with a thick and harsh mane. The defence of the magnanimous Lion, are his teeth, his crooked paws and tail. Bulls are formidable by their horns. The Boar by his tusks standing out, as it were naturall hunting spears. The Hare being a timorous creature, is naked and unarmed; but in recompence thereof Nature hath made her nimble and swift of foot. For what the more noble and courageous beasts have in arms, is supplied in the fearfull by nimbleness and celerity. Infinite are the other endowments of brute beasts, and such as can hardly be imagined or described. For if we diligently search into their nature, we shall observe the impressions and shadows of many vertues, as of magnanimity, prudence, fortitude, clemency, and docility: for they entirely love one another, follow those things that are good, shun those that are hurtfull, and gather and lay up in store those things that are necessary for life and food. Lastly, they give undoubted presages of the weather and air. They have taught men many things, and are of a most exquisit and quick sense; of rare art in vocall musick, prudent and careful for their young, and faithfull lovers of their native soil. They are religiously observant of the rights of friendship and chastity. They have their weapons whereby they are prepared, both to invade, and to defend themselves being invaded. They submit themselves to the discipline of man, practise and imitate his speech, and mutually prattle and chant one to another. They have a kind of weal-publick amongst themselves, and know how to preserve their present welfare, and to depell the contrary, being in this their own counsellors, and not tutored by man. Yea, man is beholden to them for the knowledg of many wholsome things. The consideration of which bred so great a doubt amongst the ancient Philosophers, that it was a question amongst them, whether beasts had use of reason, or no? Therefore also the wise *Solomon* sends us for examples of parsimony and diligence unto the Ant or Pismire; and *Esaias* in exprobration of the people of Israel for their ingratitude and rebellion against God, sends them to the Ox and As; for they do not only know, but reverence their masters.

Some shadow
of vertue in
beasts.

But from whence is the knowledg of these Medicins, wherewith the Art of Physick is so richly adorned, but from brute beasts, as *Pliny* affirmeth? The infallible vertue of the herb *Diētamus*, in drawing darts out of the flesh, was taught us by the Hart, who wounded with the Huntsmans darts or arrows, by means hereof draws out the weapons which remain sticking in her. Which is likewise practised by the Goats of *Candia*, as *Aristotle* writeth. The wonderfull effect which *Celandine* hath upon the sight, was learnt by the practise of Swallows, who have been observed with it to have besmeared, and so strengthened the eys of their young. Serpents rub their ey-lids with fennell, and are thought by that means to quicken and restore the decaying sight of their eys. The Tortois doth defend and strengthen her self against the biting of Vipers, by eating of savorie. Bears by eating of Pismires, expell that poison that they have contracted by their use of

Lib. 8. cap. 27.

The craftines
of Bears.

Mandrakes. And for correction of that drouziness and sloth which growes upon them by their long sleep in their dens, they eat the hearb of *Aron* (i.) Cuckopint. But the Art they use in the enticing and catching of Pismires is very pretty, they go softly to the holes or hills of the Pismires, and there lay themselves all their length upon the ground, as if they were dead, hanging out their tongue wet with their foam, which they draw not again into their mouth, before they feel them full of Pismires, which are enticed by the sweetness of the foam: And having taken this as a purging medicine, they expell by the guts, those ill humors wherewith they were offended. We see that Dogs give themselves a vomit, by eating a kind of grasse, which is from thence called Dog-grasse. Swine, when they find themselves sick, will hunt after smalt, or river lobsters. Stockdoves, Blackbirds, and Partridges, purge themselves by Bay leaves. Pigeons, Turtles, and all sort of Pullen, disburden themselves of gross humors, by taking of Pellitory of the wall. The bird Ibis (being not much unlike the Stork) taught us the use of Clysters. For when he finds himself oppressed with a burden of hurtfull humors, he fills his bill with saltwater, and so purgeth himself by that part, by which the belly is best discharged. The invention of the way of removing the Cataract of the eye, we must yeeld unto the Goat, who by striking by chance against the thorny bushes, pulls off the Cataract which hinders the sight, and covers the ball of the eye, and so recovers his sight. The benefit of Phlebotomy, we owe unto the Hippotamus or River-horse, being a kind of horse, and the Inhabitant of the River *Nilus*; who being a great devonrer, when he finds himself surcharged with a great deal of blood, doth by rubbing his thigh against the sharp sands on the bankside, open a vein, wherby the superfluous blood is discharged, which he stoppeth likewise when it is fit, by rowling himself in the thick mud. The Tortois having chanced to eat any of the flesh of a Serpent, doth make origanum and marjoram her Antidote. The Ancients found help from brute beasts, even against the dreadful and non-sparing force of lightning; for they were of opinion that the wings of an Eagle were never struck with lightning, and therefore they put about their heads little wreaths of these feathers. They were perswaded the same thing of the Seal, or Sea-calf, and therefore were wont to encompass their bodies with his skin, as a most certain safeguard against lightening. It were a thing too long, and laborious, to speak of all those other muniments of life and health (observed here and there by *Aristotle* and *Plinie*) which we have learnt of brute beasts. I will therefore end this Chapter, after that I have first added this; That we are beholding to beasts not only for the skill of curing diseases, and of preservation of health, but for our food, our rayment, and the ornament and beautifying the bodies.

Of the Faculty of brute Beasts in presaging.

What the but-
ting of Rams
signifies.

Prefages of
rain.

The sign at sea
of a storm at
hand.

THe first knowledg and skill of Prognostication, and observation of weather by the Air, was first delivered unto us from beasts of the land and water, and from fowl. For we see in dayly observation, that it is a sign of change of weather, when Lambs and Rams do butt at one another with their horns, and playing wantonly do kick, and keep up their heels. The same is thought to be presaged when the Oxe licks himself against the hair, and on the sodain fills the Air with his lowing, and smells to the ground, and when he feeds more greedily than he used to do. But if the Pismires in great multitudes fetch their prey so hastily, that they run and tumble one upon another in their narrow paths, it is thought a sign of rain; As is also the busie working of Moals, and the Cats rubbing and stroaking of her head and neck, and above her ears, with the bottome of her feet. Also when Fishes play and leap a little above the water, it is taken for a sign of rain. But if the Dolphins do the same in the sea, and in great companies, it is thought to presage a sodain storm and tempest. Wherby the Mariners forewarned, use all care possible for the safety of themselves and their ships, and if they can cast Anchor. And it is sufficiently known what the louder croaking of Frogs than ordinary portends.

But the facultie of birds in this kind of presaging is wonderfull. If Cranes flie through the air without noise, it is a sign of fair weather, and of the contrary, if they make a great noise and flie stragglingly. As also if Sea fowl flie far from the Sea, and light on the land. The cry or screeching of Owls portends a change of the present weather, whether foul or fair. *Platarch* saith, that the loud cawing of the Crow betokens winds and showers, as also when he flaps his side with his wings. Geese and Ducks, when they dive much, and order, and prune, and pick their feathers with their beaks, and cry to one another, foretell rain; and in like manner Swallows, when they flie so low about the water, that they wet themselves, and their Wings. And the Wren, when he is observed to sing more sweetly than usuall, and to hop up and down. And the Cock when he chants, or rather crows presently after the setting of the Sun. And Gnats, and fleas, when they bite more than ordinary. If the Hern soar aloft into the air, it betokeneth fair weather, if on the contrary he flie close by the water, rain. If Pigeons come late home to the Dove-house, it is a sign of rain. If Bats flie in the evening, they foreshew wet weather. And lastly the Crocodile layes her eggs in that place, which must be the bounds of the overflowing of the River *Nilus*; And therefore he that first meets with

The Crocodile
by laying her
eggs, shews the
bounds of the
increase of the
River *Nilus*.

with these eggs, tels the rest of the Countrey people, and shews them how high the flood will rise, and what inundation it will make upon their grounds: A thing most worthy of admiration, that in this monster there should be that strong faculty of presaging.

Of the industry of Fishes.

MAny sea-Fishes, when they feel a tempest coming, do gravell or ballast themselves; to the end they may not be tossed up and down at the pleasure of the waves. Others when the fury of the sea is at the height, hide themselves in the holes of rocks. But in that they swim against the stream, they do it for this cause and reason, that the force of the stream and the flood may not take from them, and strike off their scales, and that their gills may not fill with water which would hinder their swimming, and intercept their respiration. As by the same advice Cranes fly against the wind, whereas if they should fly down the wind, their feathers would be displaced and broken, and they would not be able to fly.

How Fishes provide for their safety against a storm.

How they swim against the stream.

Of the industry of Birds in the building of their Nests.

THe industry of Birds in the building of their nests is such, that it doth far exceed the art and skill of all Masons and Architects. From whence it is become a Proverb, *That men know, and can do all things but make Birds-nests.* They are built within with wooll and feathers, and such kind of soft things, which are as a kind of a pallet for the young ones. Swallows build their nests in a round form, that they may be the more firm, and less subject to be hurt by any thing that shall strike against them, and likewise more capacious. They choose their matter out of dirt and chaff, (interlacing it with many straws) as it were their plaster or lime. Those that build in trees, do make choice of the soundest boughs, as if they meant to have them as a sure foundation for the building which they should erect thereon. The Cock and the Hen do by turns sit over their eggs, and likewise fetch their meat, interchanging each others labor; neither do they ever forsake their young, before they are able to get their own living. I had at my house a great number of Sparrows nests in earthen pots; and when the young ones begun to wax pretty big, and to be covered with feathers, I made the whole nest be taken down and set upon the ground, that I and my friends might delight our selves in beholding the care of the old ones in the feeding of their young; for they feed them every one in order, skipping none, neither will they (to the wrong of the rest) give one two parts, although he gape, and be importunate for it; dividing most justly to every one his own share, according to the exact rule of distribution. And oftentimes for experiment, I would make triall with a strange Sparrow of the same age, laid near, or put among the rest of the young ones, whether the old ones would feed the stranger, as if it were legitimate. But this as a stranger and a bastard they would suffer to starve, skipping it when it gaped after the meat. And in like manner Lambs and young Kidds do in the fields, in the midst of a great flock, run every one to his own dam; who being most certainly able to distinguish between the legitimate and a bastard, will not suffer her self to be suckt but by her own young.

Of what things birds build their nests.

In what shape.

With what care Sparrows feed their young.

Of the industry of Spiders.

THe Spider spins her web with wonderfull artifice, hanging and fastening it to every tack or stay that is nigh, drawing of his thread, and running upwards and downwards, and every way. And although the diligence of the chamber-maid beats down and mars this pendulous and new-begun work, yet her feat and her hold, the Spider keeps still, neither is she, or will she desist from the work she hath begun, but in a very short time weaves a great deal more unto the ruins of her former work, than can be unweaved again with much labor. So that from hence all cloth and linnen Weavers, all Embroiderers and workers with the needle (you will easily think) have learnt their Arts, if either you observe the exactness of the weaving, the fineness of the thred, or the continuation and indissoluble knitting together of the whole web; for being abrupt, and troubled with no ends of threds at all, it resembles a thin membrane, anointed with a kind of glew, wherewith; when the prey is entangled, the Spider runs presently in, and, as it were, draws her nets, and infolds, and takes the captive after the manner of huntsmen. If this were not daily seen with our eyes, it would be thought fabulous.

How the Spiders weave.

How they catch their prey.

Of Bees.

ICannot pass in silence the great industry of Bees: For having established a kind of Weal-publick, they make election of a King, who is such a one, as in procerity of body, and excellency of feature exceedeth all the rest. He is remarkable by his short wings, his streight legs, his grave gate; and in stead of a Diadem or regall Crown, either he hath no sting, or else doth not use it, which is the Artillery of the rest. He never goeth unattended out of the hive, but always invironed with a Princely retinue, the rest of his train following after neither goes he at any time abroad, but upon urgent affairs which concerns

Bees choose themselves a King.

concerns the whole state. His progress is forewarned by the voice and sound of trumpets, and as it were with singing, and they all draw nigh. Every one gets as near to his person as he can, and when he is weary with flying, they all bear him up with their own bodies.

Their pitching their tents.

Their obsequies for their dead King.

Their justice.

On what place soever he alighteth, there they forthwith pitch their tents. If he chance to die, they go not abroad to feed, but stand all mourning round about the corpse; then carry him out of the hive, and (as it were) follow his hearse and bury him: and lastly, having with solemnity performed all the severall rites and obsequies, they choose themselves another King, for without a King they cannot live. He then taketh care of all things, having his eye every where, whilst that the rest intend the performance of the work. And supervising all, giveth them encouragement, and chastiseth negligence. For their time of going forth for food, they choose a clear and fair day; for they have a naturall faculty of presaging of the weather. They are such observers of justice and equity; that never, either with their sting, or by any other way, do they molest any creature, neither do they exercise and prepare their spears against any, but for the safegard of themselves and their hives.

Of the care of Bees.

Their watch.

Their divers employments.

They manage and order their affairs in this manner; in the day-time they appoint before their gates a station of watchmen and guarders. In the night they rest from their labors, so long, till that one (who is appointed to this charge) by one or two humms, as by a sound of a Trumpet, rowseth all the rest. Then come they together to observe what is the state of the weather, which if they foresee will be fair, then abroad go they into the fields and pastures. Some therefore bring into the hive little fascicles of flowers on their thighs; others water in their mouth, and others a dewie moisture gathered on their bodies. These are met by others, who receive their burdens, which they dispose in their due and proper places. Those that are sent out into the fields for food, are the youngest and the smallest; And therefore if the wind chance to rise any thing high, they expect untill it cease, and that the force and violence thereof be over. But if it continue violent, then do they ballast themselves with a little stone flying close by the ground, to prevent their being driven to and fro by the force of the wind. They are exceeding diligent in all their business, and do punish the sloth of the lazie ostentimes with death. Some of them are the builders, others polish the building, and the rest bring in their materials.

They punish sloth with banishment.

Aristomachus a diligent observer of Bees.

The building in their arched hives is with wonderfull artifice, being made with two doors, one to come in, and the other to go out at. They have all things alike, lest that the inequality, either of their food or labor, should give occasion of dissention. Their care is, that their houses may shew both state and handsomness. Idle drones, born for nothing but to eat, and consume the fruits of their labors, they chase from their hives. Those that chance to lose their stings, are utterly disabled, and in a short time their guts come out that way, and they die. They bring to their owners wonderfull increase of wax and honey.

Aristomachus the Philosopher doth boast, that for fifty eight years together, he had with great care been a nourisher of Bees, only that he might the better attain to the knowledg of their state and condition.

Of Pismires and Ants.

Lib. II. c. 30.

Wonderfull care.

Neither truly is the industry, diligence, and experience of the Pismire less worthy of admiration, than that of the Bees. Insomuch as that *Solomon* bids the sluggard to take an example of diligence from the Pismire. Truly, if experience did not witness it, it would seem incredible, that so small a creature should be able to store up such abundance of corn, to dispose and manage her affairs in that good order that we see she doth. *Pliny* saith, that they have among them the form of a well-govern'd and well-order'd Common-weal. For how pretty a sight is it to see them, when they seize upon a grain they have a mind to carry away, how they set to it, and lift it with head and shoulders. And how lest the corn which they carry to their store-house, should put forth and grow, they bite it at one end. If it be so bigg that they cannot carry it into their little hole, they divide it in the middle. If it be dampish, they lay it out to dry in the Sun and open air. When the Moon is at the full, they follow their work in the night; when she doth not shine, they take their rest, whereby they shew themselves to have some knowledg of heavenly things. *Pliny* affirmeth that they have their set Fairs and Markets, whither they come in great companies, and where they use to establish leagues of amity and friendship one with another. And when one marks them well, would he not think that they were in conference one with another, and that they did discourse among themselves of their business? Do we not see that the often trampling of their little feet doth wear a path even upon hard flint stones?

There is nothing but may be attained by diligence.

From whence we may note, what in all kind of things is the effect of assiduity. They say also that they perform the rites of buriall one unto another, after the manner of men.

What

What words shall I use (saith *Plutarch*) to express sufficiently the diligence and industry of the Pismires? There is not among all the great things in nature, a sight of greater wonder than these: For in the Pismires are seen the marks of all vertue. Their great meetings argue that they maintain a kinde of friendship.

Their alacrity in the undergoing of their labors, seems to shew their fortitude and magnanimity; and lastly, they are eminent examples of temperance, providence, and justice. Their mutuall charity appeareth in this, that if one of them that is not loaden meets another, (in one of their narrow paths) that is, he will give him the way, that he may the better go on in his intended journey. They say that the first entrance into their hole, is not straight, but full of many diverticles and crooked paths, which all end, which will bring you to three little cels; in one of which they have their conventicles; in the other, they lay up their provisions; and in the third they bury the carcases of their dead. This doth *Plutarch* speak concerning Pismires.

The forms of all vertues expressed in Pismires.

Of Silk-Worms.

With the industry of these creatures, I shall not unfitly joyn that of the Silk-worms; of whose pains and care, both in the making of their nests, and the spinning of their thred and bottoms (wherewith Kings are so magnificently adorned) Philosophers have written very strange things.

And who can chuse but wonder at those great endowments of skill and knowledg, and that exceeding industry, (the mother of so much wealth) in the little body of so small a creature? The providence therefore of God, doth not only appear in this, that he hath adorned each creature with a peculiar and proper endowment, but in this especially, that on the least creatures of all, he hath bestowed the greater portion of skill, industry, and ingenuity to supply their defect of bodily strength.

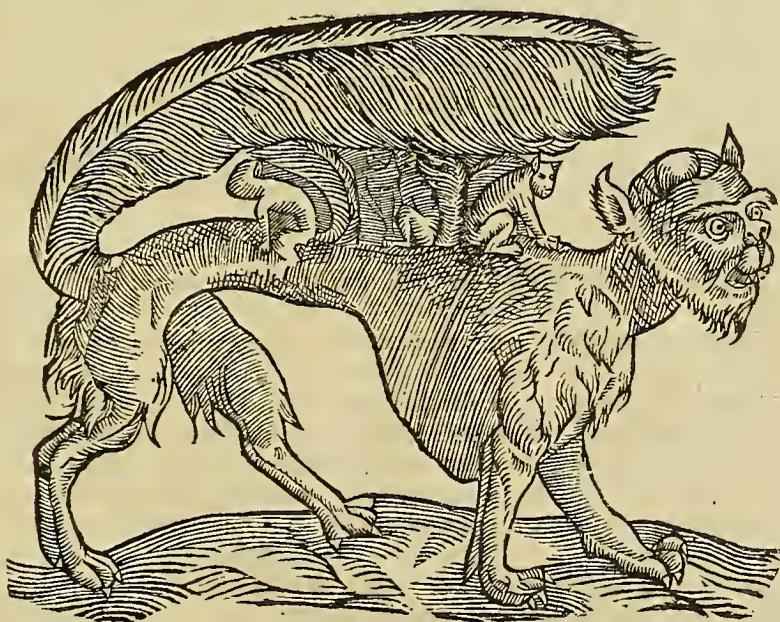

Diligence the mother of wealth.

Of the love of Beasts one towards another, and to their young.

Plutarch writeth, That all kind of creatures bear a singular love, and have a kind of care of those that are generated of them, and the industry of the Partridges this way is much commended; for during the time that their young ones are weak and unable to fly, they teach them to lye upon their backs, and to hide themselves among the clods on the ground, that so being almost of the same colour, they may not be discerned by the Faulkoner. But if notwithstanding, they see any body coming, and that he is near them, they do with a hundred dodges and stoopings of themselves, as if they were weary with flying, entice him away from their young to follow after them, and when they have their purpose, they then, as if they had recovered some fresh strength, fly quite away; who can but wonder at this both affection and subtilty?

The industry of Partridge in preserving their young.

In *Florida* part of the *West-Indies*, they have a beast, which for the variety and deformity of it I cannot pass over in silence; the natives call it *Succarath*, the Canibals, *Su-*

It keeps for the most part about the rivers, and the sea-shore, and lives by prey. When he perceiveth that he is pursued by the Huntsman, he gets his young ones upon his back, and with his tail, which is very long and broad, he covereth them, and so flying, provideth both

both for his own and their safety; neither can he be taken by any other way but by pits, which those savage men use to dig in the places near which he is to run, into which at unawares he tumbles headlong. This picture of him here, I drew out of *Thevet's Cosmographic*.

Tom. 2. lib. 23.
cap. 1.

How Hares provide for themselves and their young, for fear of hunters.

Neither are those things less wonderfull that are reported of Hares, for when they would go to their seat, they sever their young, and commit them to the trust of divers places, it may be two acres asunder one from another, lest peradventure a Huntsman, a dog, or any man should chance to come that way, and they might be in danger to be lost at once. And then after they have traced up and down, hither and thither, and every way that the dogs may not trace them, nor the huntsman prick them, they take a leap or two, and leap into their forms.

Nor inferior to this is the craft of the Hedghog, for when the Fox pursueth him, and is now at his heels, he rowls himself up in his prickles like a chestnut in the outward shell, so that every part being rounded and encompassed with these sharp and dangerous pricks, he cannot be hurt: and so saves himself by this trick. For his young he provides in this manner:

The care of the Hedghog to provide for her young.

In the time of Vintage he goes to the vines, and there with his feet he strikes off the boughs and the grapes, and then rowling his body makes them stick upon his prickles, and so doth (as it were) take his burthen upon his back, and then returns to his hole; you would think that the grapes did move of themselves; the prey he divides between himself and his young.

Of the affection of Birds, and of Dogs towards their Masters.

The piety of Storks.

The young Stork provides for the old, which is disabled by age; and if any one of their equals come to any mischance, that he is not able to fly, they will give him their assistance, and bear him on their backs and wings. And therefore this affection and piety towards the old ones, and (as it were) brotherly love towards their equals, is commended in the Stork.

The Hen in any kind of danger gathers her chickens under her wings, and (as it were) with that guard, defends them as well as she can. For their sake she exposeth her self to the cruelty of the fiercest beasts; and will fly in the eyes of a Dog, a Wolf, or a Bear, that by chance offers to meddle with her chickens.

The fidelity of Dogs.

But who is there that doth not admire the fidelity and love of dogs towards their Masters, whereby they recompence them for their keeping? A Dog will never forsake his Master, no, if he be never so hardly used. For there is no man can find a stick hard enough to drive that Dog clean away from him which hath once taken a love to him. There is no kind of creature that doth more certainly and readily remember his master; he will know the voice of all the household, and of those which frequent the house. There cannot be a trustier keeper, (as *Cicero* himself saith) than a Dog is; I speak not of their faculty of smelling, whereby they follow their Masters by the foot, and find them, neither do I speak of those infinit examples of the fidelity of Dogs, which were too long to rehearse.

Doves free from adultery.

Pigeons, as well the cock as the hen, although they are all very venereous, yet they know no adultery; yea, and the Hen will bear with the frowardness of the cock, neither will she ever leave him, but reconciling him unto her by her officious diligence, bring him to his wonted dalliance and kisses, neither is the love of either of them less towards their young.

Turtles never couple twice.

There is the like mutuall bond of love between Turtles; for if one of them die, the survivor never solicits Hymen more, neither will he ever chuse other seat than a dry withered bough.

Of the strength, piety, docility, clemency, chastity, and gratitude of Elephants.

Among the beasts of the field, there is none more vast, more strong, or more to be feared than the Elephant. His strength is sufficiently shown by those towred Castles of armed men which he carries, and fiercely rusheth with into the battail. The *Roman* souldiers, being otherwise of undaunted spirits, yet in that battail which they fought against *Pyrrhus*, being terrified with the vastness and immanity of these bodies, which they had never before seen, presently turned their backs and fled; which notwithstanding, it is a wonderfull thing what Stories naturall Philosophers tell of the vertues of the Elephant.

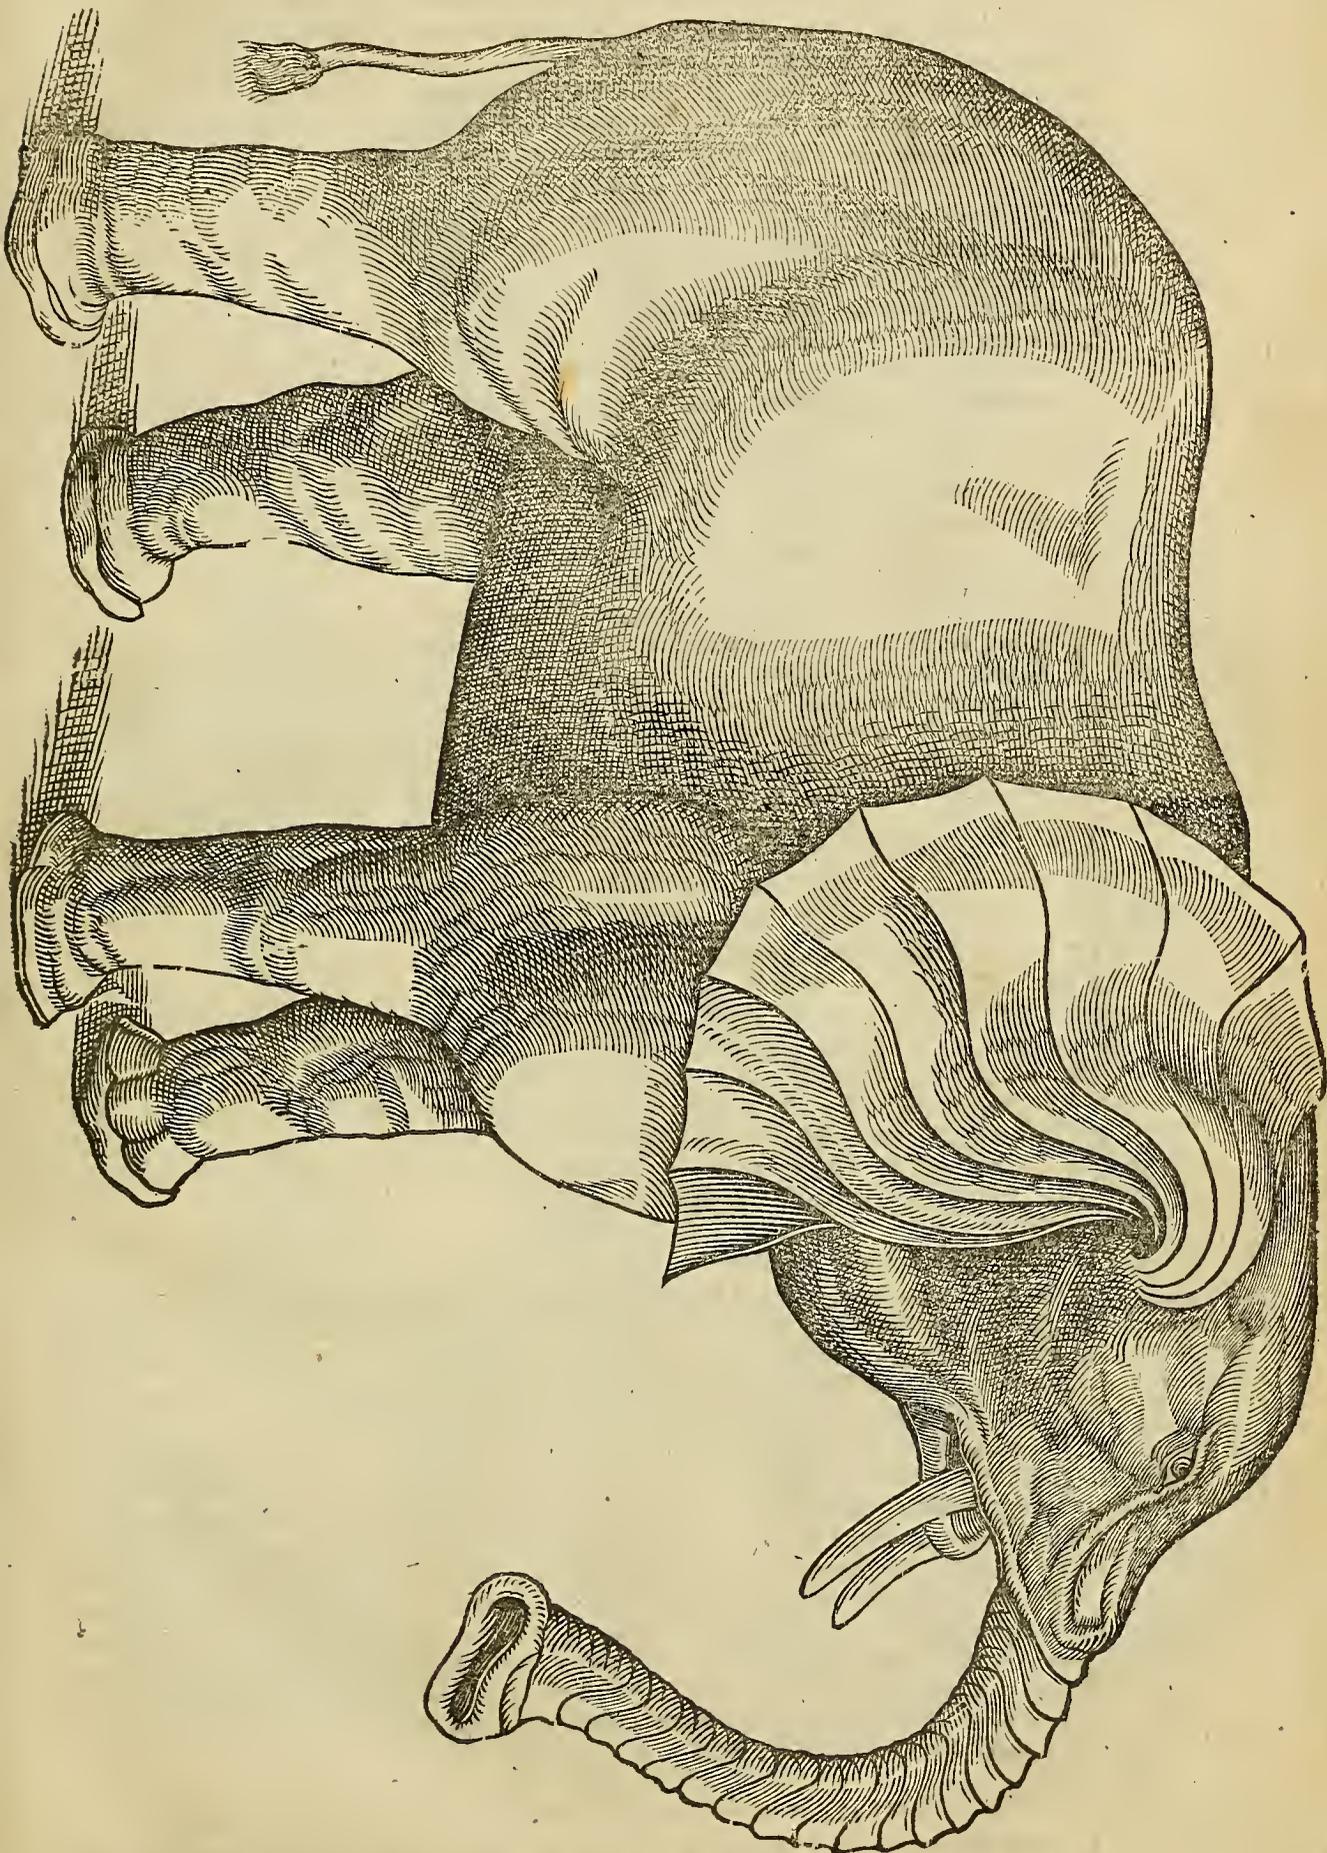

Lib. 8. cap. 1.

The religion of the Elephant.

Plinie writeth, that an Elephant cometh very near to the understanding that men have, and that he hath a rude kind of knowledg. of language; that his facility and obsequiousness is wonderfull, that his memory in the performance of his wonted duties, is no less wonderfull. And for Religion (*Plutarch* saith) that they pray unto the gods, and sprinkle and purge themselves with salt water, and that with great reverence they worship the Sun at his rising, lifting their trunks up towards heaven for want of hands. *Plinie* addeth, that they do with the like reverence worship the Moon and the Stars. For it is related in

the

the Histories of the *Arabians*, that at a new Moon the Elephants go by troops down unto the rivers, and there wash themselves with water ; and being thus purged, kneel down and worship the Moon, and then return to the woods, the eldest going first, and the other following after according to their age.

Plutarch reporteth, that it hapned once, that among the Elephants which were taught at

Rome

Plin. lib. 8.
cap. 5.

Rome against the Panegyrick shews, there was one that was something dull, and not so docile as the rest, which made him be despised by his fellows, and often beaten by his master. But that this Elephant, that he might supply by diligence what he wanted in wit, was oftentimes observed in the night, by the light of the Moon, to be practising and conning what he had learnt of his master in the day-time. For they were wont to be taught to make letters, and also to present garlands to the spectators, and other such like tricks. But they can never be brought to go aboard a ship, to be carried over the sea into any strange land, unless their master give them his word to assure them that they shall return again to their own native soil. They never hurt any one that doth not first provoke them. They never gender but in private out of sight, an argument of their modesty.

Of the Lamprey.

Lest that the heat of affection may seem to lie quenched under the waters, let us by one example, (it were an infinit thing to speak of all) see in what kind of mutuall love the creatures of the water come short of those of the land. The Lamprey of all the creatures of this kind doth worthily bear the praise for its piety towards those of whom it was generated, its affection towards those that are generated of her; for first she breeds eggs within her, which in a short time after are spawned. But she doth not as soon as her young ones are formed and procreated, bring them straight-way forth into the light after the manner of other fishes, that bring forth their young alive, but nourisheth two within her, as if she brought forth twice, and had a second brood. These she doth not put forth before they are of some bigness, then she teacheth them to swim and to play in the water, but suffers them not to go far from her; and anon gapes and receives them by her mouth into her bowels again, suffering them to inhabit there, and to feed in her belly so long as she thinks fit.

The savage or brute beasts may be made tame.

Cosmograph.
Tom. 2. lib. 19.
cap. 7.

THevet reporteth, that the Emperor of the Turks hath at *Caire* (it was once called *Memphis*) and at *Constantinople*, many savage beasts kept for his delight, as Lions, Tigers, Leopards, Antilopes, Camels, Elephants, Porcupines, and many other of this kind. These they use to lead about the City to shew. The masters of them are girt with a girdle hung about with little bells, that by noise of these bells the people may be forewarned to keep themselves from being hurt by these beasts. But in hope of reward and of gifts, they shew them to Ambassadors of strange nations, before whom they make these beasts do a thousand very delightfull tricks, and in the interim they play their countrey tunes and musick upon their pipes and other instruments, and make many sports in hope of gain.

That Fishes also may be tamed.

But it is far more wonderfull, that the creatures of the water should be made tame, and be taught by the art of man. Among which, the chiefest are held to be the Eel. The same things also are reported of the Lamprey. For we have it recorded, that *Marcus Crassus* had a Lamprey in his Fish-pool, that was so tame, and so well taught, that he could command her at his pleasure. Therefore as a domesticall and tame beast he gave her a name, by which when he called her, she would come. And when this Lamprey died, he mourned for her in black, as if she had been his daughter. Which when his colleague *Cneus Domitius* objected to him by way of reproach, he replying, told him, That he had buried three wives, and had mourned for none of all them three.

Of the Lion, the Ichneumon, and those other beasts which are not easily terrified.

The providence of the Lion in his going.

The Lion when he goes, hath his claws always clutched, and (as it were) put up in their sheaths, not only because he would leave no mark of his feet, whereby he may be traced and so taken, but because by continuall walking he should wear off, and blunt the points of his claws. Bulls when they fight charge one another with their horns, and like valiant souldiers, provoke and animate one another to the battail.

The greatest are terrified by the least.

The Ichneumon seems to imitate the most valiant souldier in his preparation and access to battail; for he bedawbs himself with mud, and doth (as it were) buckle and make tite his armor, especially when he is to encounter with the Crocodile; who although he bee a vast beast, is put to flight by this little creature. And this truly hath been observed to be by the singular providence of Nature, that the most vast creatures are terrified by the least things, and such from whence there can arise no danger; so they say the Elephant doth startle at the grunting of an Hog; and the Lion, at the crowing of a Cock; although it be reported of the Lion, that no fear can make him turn his face. These kind of fears, terrors, and affrightments, arising upon light and most ridiculous occasions, we find as well in the ancient as modern Histories of our times, to have dispersed and put to flight mighty legions of souldiers, and most potent armies.

That men were taught by Beasts to polish and to whet their weapons, and to lye in ambush.

Souldiers are carefull to keep their weapons from rust, and therefore they carry them to the Armorers to be polished. But in this care, many beasts are nothing inferior un-

to them; for Boars whet their tusks against they fight. And the Elephant knowing that one of his teeth is doubled with digging at the roots of trees to get meat, keepeth the other sharp, and touches nothing with it, preserving it for his combat with the *Rhinocerot* his

The craft of the Rhinocerot about to fight with the Elephant.

enemy; but the craft of the Rhinocerot is very remarkable, that being in continuall enmity with the Elephant, at the time when he prepares for the battail, he whets his horn against a rock, as if it were with a whetstone; nor (if he can chuse) will he strike any other part of the Elephant but the belly, because he knows that part of the Elephant is so tender, that it may be easily pierced. This beast is in length equall to the Elephant, but in height he is inferior unto him, by reason of the shortness of his feet; he is of a palish yellow colour, and full of many spots.

Of Cocks.

Cocks are Kingly and martiall Birds.

Cocks are kingly Birds, and therefore Nature hath adorned them with a comb, as with a princely Diadem; and wheresoever they come, their magnanimity and courage makes them kings. They fight with their beaks and their spurs, and with their martiall voice they fright the Lion, who is otherwise the king of beasts.

Of Conies.

Conies have taught us undermining.

Conies have taught us the art of Undermining the earth, whereby the most lofty Cities and structures reaching the very skies, are by taking away their foundation levelled with the ground.

Marcus Varro writes, that in Spain there was a town, and that no mean one, which standing on a sandie ground, was so undermined by a company of Conies, that all the houses tumbling and falling down to the ground, the inhabitants were faine to depart and seek new dwellings.

Of Wolves.

The deceits and ambushes of Wolves.

Men have learnt the arts of waging War from the Wolves, for they come out by troops, and lye in ambush near the towns which they have appointed, and then one of them runs unto the town and provokes the dogs. And making as if he run away, incites the Dogs to follow him, untill he hath gotten them unto the place where their ambush lyeth, which on a sodain appeareth, and rusheth out upon them. And so they kill and eat all, or as many of the dogs as they are able to catch.

Of the Fox.

The craft of the Fox.

In subtilty and craft the Fox exceedeth all other beasts: when in the chase the Dogs are at his heels, he berays and bepiffes his tail, and swings it in the face and eys of the Dogs that follow him, and so blinding them, in the mean time gets ground of them. To fetch the Hens down from their perch, he hath this devise, he shakes and swings his tail upwards and downwards, as if he meant to throw it at them; which they fearing tumble down, and he takes up one of them for his prey. His wariness when he passeth over a River that is frozen, is wonderfull; for he goes softly to the bank, and lays his ear to listen, if he can hear the noise of the water running under the ice. For if he can, back he goes, and will not venture to pass over. The knowledg of which thing he could never meerly by his subtilty and craft attain unto, but that of necessity he must have some faculty of reasoning joined with it; which by discourse, and by proving one thing by another, arrives at this Conclusion: whatsoever is liquid and maketh a noise, is in motion; whatsoever liquid is in motion, is not concrete and frozen; that which is not concrete and frozen, is liquid; whatsoever is liquid, will not bear a heavier body; whatsoever will not bear a heavier body, cannot with safety be adventured on; and therefore back again must I go, and not pass over this River.

The Fox seems to reason with himself.

His Soriter.

Of Swine.

Swine, if in the woods, they hear any one of the same herd with them crying out, they straight make a stand; and marshalling their forces, haste all, as if they had been warned by the found of a martiall trumpet, to the assistance of their fellows.

Of the fishes Scarus and Anthia.

The love of Fishes one to another.

Plutarch reports of the *Scari*, that when one of them chances to swallow a hook, and be taken, the rest of the same kind come to his rescue, and shearing the Line with their teeth, set him at liberty. But the readines of the *Anthia* to the mutuall assistance of one another, is yet more manifest; for by casting the Line upon which the hook hangeth on their back, with the sharpness of their fins they cut it asunder, and so set free themselves and their captived fellows.

Of the Pilot-fish.

There is great kindness between the Pilot-fish and the Whale; For although in bulk of body the Whale so far exceed him, yet he leads the Whale, and goes always before him

him as his Pilot, to keep him from running himself into any straight or muddy place, whence he might not easily get out. And therefore the Whale always follows him, and very willingly suffers himself to be led by him, it being for his own good. And in like manner he gets into the Whales mouth, and there lodging himself, sleeps when he sleeps, and leaves him not either by day or night.

The Whales
pilot or guide.

Of Cranes.

CRanes when they are to take a long journey into some Countrey cross the seas, put their company in so good order, that no Captain can put his souldiers in better. For before they stir out of any place, they have (as it were) their trumpets to call them together, and encourage them to fly. They come together, and then fly up on high, that they may see afar off, choosing a Captain whom they are to follow. They have their Serjeants to take care of their ranks, and keep their nightly watches by turns. *Plutarch* tells us that the Crane, which is appointed to stand Sentinell for all the rest, holds a stone in her foot, to the end, that if she chance to give way to nature and sleep, she may be waked by the noise of the falling stone. The leader lifting up his head, and stretching out his long neck, looks about him far and wide, and gives warning to the rest, of any danger that may befall them. The strongest lead the way, that they may the better with the flapping of their wings break the force of the air, and this they do by turns. And that they may the easilier prevail against the force and opposition of the winds, they dispose their company into a wedg in the form of the Greek letter Δ or a triangle; and being skilfull in the stars, they foresee when tempests are coming, and fly down to the ground to keep themselves from the injury of the approaching storm.

Cranes order
themselves in
ranks.

The sentinell
Crane.

Of Geese.

THe Geese of *Sicilie* do with great wariness take care, that by their keeking and their noise, they do not expose themselves to the rapacity of Birds of prey: for *Plutarch* saith, that when they are to fly over the hill *Taurus*, for fear of the Eagles that are there, they hold stones in their mouths to keep themselves from gagling, untill that they come unto a place where they may be secure.

The care of the
Geese that their
gagling do
them no harm.

Of Dragons.

Neither are the Dragons less crafty; for thus do they overcome those vast and otherwise invincible beasts the Elephants. They lye in ambush, and sodainly set upon the Elephants where they fear no such matter, and involve their legs with the twines of their tail, in such sort, that they are not able to go forward; and stop their nostrils with their heads, so that they cannot fetch their breath, they pull out their eys, and wheresoever they find the skin most tender, there they bite and suck the blood untill they make them fall down dead. *Pliny* saith, that there are Dragons found in *Aethiopia* of ten Cubits long, but that in *India* there are Dragons of an hundred foot long, that fly so high, that they fetch Birds, and take their prey even from the midst of the clouds.

The craft of
Dragons fight-
ing against the
Elephant.

Lib 8. cap. 11.
& 12.

Of the Fish called the Fisherman.

This fish is called the Fisherman, because he hunts and takes other Fishes, which he doth almost by the same cunning which the Cuttell uses; for he hath hanging at his throat a certain bag, like the Wattels of a Turkey-cock. This when he listeth he casteth out, and layeth before the little Fishes for a bait, and then by little and little draws it up again, untill he catch for food the little Fishes seiing upon it as a prey.

The craft of the
Fisherman fish
in taking her
prey.

Of the Cuttell Fish.

VVonderfull is the craft of the Cuttell-fishes, for they carry a bladder at their neck full of a black juice or ink, which they pour forth as soon as they feel themselves taken; that so they may blind the eys of the Fishermen, as *Plutarch* saith, and as *Aristotle* witnesseth, they with their long fangs do not only hunt and take little Fishes, but oftentimes also Mulletts.

The craft of
the Cuttell to
save her self.
Lib. 9. de Hist.
animal. cap. 37.

Of the arms or weapons of brute Beasts.

Brute beasts are naturally so furnished with arms, that they have no need to get, make or borrow in any other place.

And some of them nevertheless are so furnished with such arms, that they captivate those which hold them prisoners; an example of this is the *Torpedo*, which doth not only hurt by touch, but also by the net being between, he breaths such a quality from him, as stupifies the hands of the Fishermen, so that they are forced to let go their nets, and so let him go; moreover if it touch a ship it makes it stay. *Thevet* writes, that the *Persian* bay towards *Arabia*, nourishes a fish equal in length and thickness to a Carp, on every

Cosmogr. 10m. 1.
lib. 10. cap. 17

side encompassed with sharp and strong pricks, like our Porcupine, with which he fights against all kinds of fish. If a man chance but to be lightly hurt either with these or his teeth, he will die within 24 hours.

Of the fish *Utelif*.

HE saith moreover, That as he was carryed by force of tempest through the Atlantick Ocean, he saw this fish, having (as it were) a Saw in his forehead of three foot long, and four fingers broad, armed on each side with sharp spikes; they call it *Utelif* in their Countrey speech.

Of the fish *Caspilly*.

THere is another fish to be seen in the Arabian-gulf, which the Arabians call *Caspilly*, it's two foot long, and as many broad, it hath a skin not much unlike a Dogfish, but armed with spikes, one whereof he carries in his forehead a foot and half broad, in sharpness and force of cutting not much short of a graver or chissell: with this weapon, when she is oppressed with hunger, she assails the first fish she meets, neither doth she give over, before she carry her as a prey whither she please, as *Thevet* saith he hath seen.

Tom. 1. lib. 5.
cap. 2.

Of Crabs.

CRabs and Lobsters, though in the quantity of their body they be but small, yet they use their forked claws before, not only in feeding but also in defending themselves and assailing others.

Of the docility of Beasts, and first of the Dog.

BEasts are apt to learn those things which men desire, whereby they shew themselves not wholly void of reason. For Dogs, Apes, and Horses learn to creep through the Juglers hoops, and rise on their hinder feet, as though they would dance. *Plutarch* tells, that a Jugler had a Dog which would represent many things upon the stage besitting the occasion and argument of the Play; amongst the rest, he exceeded all admiration in that, that taking a sopotifick medicin, he excellently feigned himself dead; for first, as taken with a giddiness in his head he begun to tremble, then presently fell down, and lying on the ground, as it were contracted his dying members, and lastly, as if truly dead he wax'd stiff; and moreover suffered himself diversly to be fitted according to divers parts of the Theater, the fable so requiring. But when he, by those things that were said and done, knew it was time to rise, he first begun to move his legs by little and little, as if he had been wakened from a sound sleep; then presently with his head a little lifted up, he looked this way and that way, to the great admiration of all the beholders; and finally rise up and went familiarly and chearfully to him he should; the which sight the Emperor *Vespasian* (who was then present in *Marcellus* his Theater) never saw any which more delighted him.

The wonder-
full docility of
Dogs.

A spectacle full
of admiration
and truth.

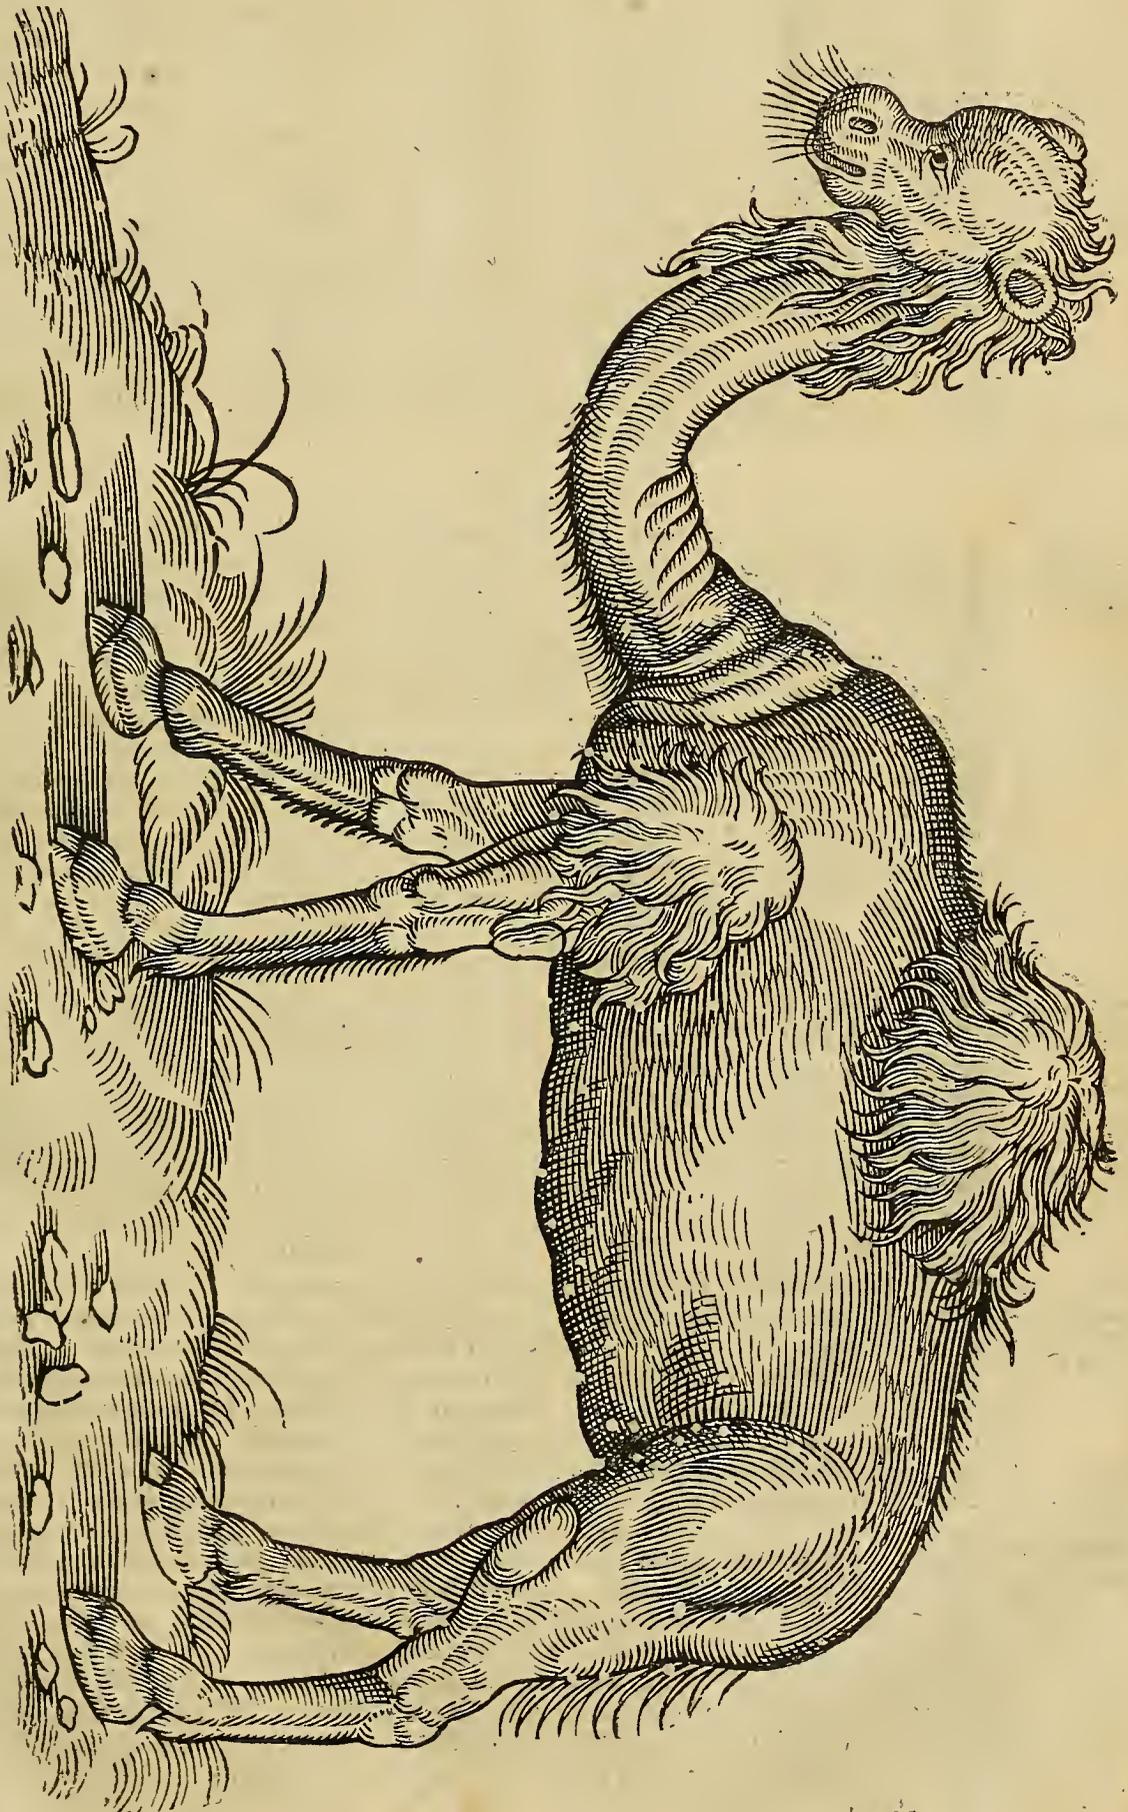

Of the Ape.

AN Ape is a ridiculous Creature, and which makes men much sport in imitating their actions. There hath been seen an Ape which would pipe and sing, and besides dance and write, and endeavour to perform many other things proper to men. I remember I saw in the Duke of *Somes* house a great and curst Ape, who because he much troubled many, had his hands cut off, who suffering himself to be cured, when the wound was cicatrized, he grew more milde and docile. Wherefore cloathed in a green coat, and girt over his loius with a girdle, he carried hanging thereat a case of spectacles, a pair of knives, and a child's handkerchief. He was committed to the charge of the Master-cook to teach, because he had taken up his lodging in the Chimney-corner, he was taught many tricks and feats. If at any time he swerved from his doctrine and precepts, in a trice the whip was upon his back and loins, and much was abated of his daily allowance; for as *Persius* saith, The belly is the Master of Arts, and sharpener of wit. By these means he profited so in a short time, that he much exceeded all the Apes of his time in the glory of his wit; and there was none counted more skilfull in leaping and dancing to the pipe, running up a pole, and nimbly leaping through his Masters legs. To conclude, he performed all the actions of a strong Ape, and very reverently carried up dishes with the waiters and serving-men, and made clean the dishes and platters by licking, and did much other drudgery, so that he was commonly called, Master *John Do-all*. At dinner and supper sitting in a chair, he said grace, and cast his eyes up towards heaven, and rouled them this way and that way, and smote his breast with the stumps of his hands with much lamentation, and imitated prayer by the gnashing or beating together of his teeth. He would turn up his tail to any that offended him, (for his coat scarce covered half his buttocks lest he should have filed it) he made much other pastime, always going upright by reason of the cutting away of his hands, unless at any time through weariness he were forced to sit on his buttocks.

Gal. lib. 1. de
usu partium.

Of the Camels.

THe *Camell* is a very domesticall and gentle beast, and which is easily tamed and taught all kind of obedience and service; although some of them are cruel, wilde and

trouble-

Camels both tame and wilde.

The easie and not chargeable keeping of Camels.

Camels know when they have a sufficient load.

Camels both to carry burdens, and to ride upon.

A mighty troop of Camels.

The diligence of Falconers in training up their Hawks.

The fight of the Hern and Falcon.

To sing like a Nightingale.

The voice to beasts is of the same use, as speech is to men.

We are as ill as deaf, when we hear an unknown language.

troublesome by biting and striking such as they meet, no less than untamed horses. There is no need to house them in the night, for they may be left in the plain fields in the open and free air, feeding upon the grais and trees and cropping the tops of the thistles, neither in the morning do they any whit the worse undergoe or carry their burdens. They are not put to carry burdens before they be four year old. The *Arabians* geld them young, that they may enjoy their labour the longer, neither being gelt do they rage for love or desire of Vnery. At the putting in of the Spring they endure hunger and thirst for eight dayes; they are so dutifull, that at the beck of the Turkish slaves, or but touched on the neck with a twig, they presently kneel on the ground to take up their burden, neither do they lift themselves up before that they find they have a sufficient load laid upon them. Those that have but one bunch upon their back are of *Africk*; but such as have two bunches are of *Asia*, or *Scythia*. Those kind of Camels that are the bigger are used to carry packs, but the lesser are used to ride upon, as our horses are. They love nothing so well as beans, and yet they live content with four handfuls of beans for a day. The greatest wealth of the *Arabians* consists in Camels, and so they estimate their riches, not by the quantity of silver, or gold, but by the number of Camels. The *Turkish* Emperour (*Thevet* being the reporter) made a Captain over the herds of his Camels, giving him a great troop of *African* and Christian slaves, that they might be the better looked unto. I have heard it reported (saith *Thevet*) by certain *Arabian*, *African* and *Jewish* Merchants who were present, at that time when *Sultan Selim* the first of that name, besieged *Caire* in *Ægypt*, (which in former times was called *Memphis*) that there then was in that Emperours army sixty thousand Camels, besides a mighty company of Mules.

Of ravenous Birds.

But let us take a view of Falconers teaching ravenous Birds, how with swift wings carried aloft into the air, they may seize upon other Birds, and cast them down dead to the ground; in performance whereof, they often too freely soare up to the clouds, so that they carry themselves out of the Falconers sight, with a desire to sun themselves, neglecting in the mean time their designed prey.

The Hern when she sees her self kept under and below the Falcon carried up by his strong wings with a marvailous swiftness, with her beak, which is long and sharp, hid under her wings, and turned upwards, she receives the Falcon blinded with the heat of fight and desire of prey, carelessly flying down and rushing upon him; so that he often strikes him through the gorge, so that oft times they both fall down dead to the ground. But if the Falcon without harm escape the deceits by art, and the happy turning of his body, and the Hern be not cast down, the Faulconer calling her back with never so loud a voice, yet by setting up her Feathers she dares her to the pretended fight.

That Birds have taught us muscally tunes.

The Nightingales are sweet and excellent singers, tuning their notes with infinite quaverings, and diversities of sounds, so prettily and sweetly, that humane industry can scarce equal the sweetness thereof, by so many muscally instruments; so that we say, he sings like a Nightingale, who varies his voice with much variety. In which thing Birds much excell men, because they have that admirable sweetness of singing from nature it self without any labor of learning; which men can scarce attain to in any school of musick, by having their ears a thousand times pluckt by the hand of a curst master.

That Beasts know one anothers voice.

Beasts know one another by their voice, so that they may seem to talk and to laugh together, whilst flattering with their ears, they pluck in their noses with a pleasant aspect of their eyes; and as speech is given to men, so Birds have their naturall voice, which is of the same use to them, as speech is to us. For all Birds of the same species, as men of the same countrey, chant and chirp to one another, when men understand not the speech of other men, unless of the same Nation. Wherefore the *Scythian* tongue is no more profitable to one living in *Egypt*, than if he were dumb; nor the *Egyptians* understand it no more than if they were deaf. Wherefore an *Egyptian* is dumb and deaf to a *Scythian*. This those which travail well understand how many dangers, how many troubles they undergo, because they cannot express their minds, and require things necessary for life. Wherefore to the assistance of this unprofitable tongue, we are compelled to call the rest of the members, and to abuse the gestures of the head, eyes, hands, and feet. Truly the condition of brute beasts is not so miserable, seeing that all of the same kind wheresoever they be, may answer each other with a known voice. Truly if any should hear a *German*, *Briton*, *Spaniard*, *Englishman*, *Polonian*, and *Greek*, speaking amongst themselves in their native tongues, not understanding any of them, he could scarce discern, and certainly judg, whether he heard the voice of men or of beasts.

That Birds may counterfeit Mans voice.

Linets, Larks, Pies, Rooks, Daws, Crows, Scares, and other such like Birds, speak, sing, whistle, and imitate the voices of men, and other creatures. In this Parrats excell all other, being wondrous skilfull imitators of mens voices, and very merry, but specially when they have drunk a little wine.

Parrats are wonderful imitators of mans voice.

Plutarch reports that there was a Barber at *Rome*, who kept a Pie in his shop, which spoke exceeding well, and that of her own accord, none teaching her, when she first heard men talking together; she imitated the voice or cry of all beasts shee heard, as also the sound of Drums, and the sound of Pipes, and Trumpets: to conclude, there was nothing which she did not indeavour to imitate. There have been Crows that have spoken and articulately sung songs and Psalmes, and that of some length. To which purpose the History of *Macrobius* is notable; for he tels that there was one amongst those, who went forth for luck sake to meet with *Augustus Caesar*, returning from the war against *Antonius*, who carried a Crow, which he had taught plainly to pronounce this salutation, *Salve Caesar Imperator Augustissime*, that is, *God save thee, O most sacred Emperor Caesar*. *Caesar* taken with the novelty of this spectacle, bought this obsequious bird with a thousand peeces of silver. *Pliny* and *Valerius* have reckoned up amongst prodigies, Oxen and Asses that have spoken. I omit infinit other things recorded by the ancients, *Plato*, *Aristotle*, *Pliny*, *Plutarch*, and other Philosophers of great credit, of the docility of beasts, and their admirable felicity of understanding. Which things, if untrue, these learned men would never have recorded in writing, lest so they might brand with vanity, (then which nothing is more base) the rest of their writings to posterity in all ensuing ages.

A talking Pie.

Lib. 2. Saturn. cap. 4.

Of the Sympathy and Antipathy of Living Creatures amongst themselves.

Having briefly described the understanding of brute beasts, it seems not impertinent to set down some things more worthy of knowledg, happening unto them by reason of Sympathy and Antipathy; that is, mutuall agreement and disagreement, which happens not only to them living, but also dead, by a certain hidden property, through occasion whereof some desire, other shun, and others prosecute one another even to death. In testimony whereof; The Lyon the King of Beasts excelling all other in courage and magnanimity, fears the Cock, for he is not only terrified by his presence, but also by his crowing being absent. So an Elephant fears a Hog; but he is so afraid of Mice and Rats, that he will not touch the meat that is given him, if he smell that it hath been defiled with such creatures. There is deadly hatred between the Elephant and Rhinocerot; yet when the Elephant is furious and angry, he becomes quiet and calm at the sight of a Ram. A Horse is so afraid of a Camel, that he cannot indure his sight. The Dog hates the Wolf, the Hart flies the Dog. The Snake flies from and fears a naked man, and followes him being clothed. There is deadly hatred between the Aspis and Ichneumon, for he when he hath rowled himself in the clay, dries himself in the Sun, and so being covered over (by doing thus divers times) as it were with shells, or armour, he enters into combat, stretching out his tail, and presenting his back, untill he get opportunity to choak his adversary, by leaping and fastening on her jaws, by which stratagem he also kills the Crocodile. The green Lizard is a capitall enemy to the Serpent, but most friendly to man, as *Erasmus* witnesseth by many Histories concerning that matter, in his Dialogue of Sympathy and Antipathy. There is a great deal of hatred between a Man and a Wolf, which is most manifest by this, that if the Wolves first see a man, his voice is taken away, and his intended cry hindered. If the Weasell intend to set upon the Aspis that most venomous Serpent, shee arms her self by eating Rue, as a most certain Antidote. The Ape fears the Torpedo, as *Erasmus* manifests by a pleasant history in the forementioned Dialogue; where also he prettily shews the deadly hatred between the serpent called Areus and the toad. The like hate is between the Owl and Crows, so that the Owl dares not go out, fly abroad, or seek her food unless by night. The water or River fowl are afraid of the Falcon; that if they but hear her bells, they had rather be killed with staves and stones, than take wing to flie into the air. So the Lark yelds herself to be taken by a man, lest shee fall into the talons of the Hobby. The Castrill, or Merlin is naturally a terror to Hauks, so that they both shun his voice and presence.

The Lion fears a cock.

A horse fears a Camell.

What fowl fear the Falcon.

The Kites are all at perpetual enmity with the Crows, wherefore the Crow alwayes gets away the Kites provision. All kind of Pullen fear the Fox. The Chicken fears neither a Horse, or an Elephant; but scarce hatched, it presently runs away at the voice or sight of a Kite, and hides it self under the hens wings. The Lambe and Kid flie from the Wolf when they first see him, neither doth death give an end to that hatred, but it supervives their funerall. An Experiment whereof (they say) is, that if one Drum be headed with Wolves skins and another with Sheeps, and beaten up together, you shall scarce hear the sound of the Drum covered with sheeps skins. And besides, if you string one Harp with strings made of sheeps guts, and another with strings of Wolves guts, you cannot bring

The enmity between the Kites and Crows. The discord between the Lamb and Wolf is not ended by death.

it to pass, by any art, to make them agree and go in one tune. It is reported from the experiments of many men, that if a Wolves head be hanged up on high in the place where Sheep are, that they will not touch the grafs how good and fresh toever it be, nor rest quiet in any place, but tumultuously run up and down, untill all such kind of terror be taken away. The hate betwixt Mice and Weasels appears by this, that if you mix never so little of the brains of a Weasell in the rennet, with which you cruddle you Cheese, the Mice will never gnaw or touch that cheese. The Linner doth so hate the bird *Florus*, that both their bloods put into one vessel cannot be mixed together. A Wolves head hung up in a dove-house, drives away Poll-Cats and Weasels. The Panther and Hyana burn with so great hatred, that if both their skins be laid one against the other, the Panthers will shed the hair, the hairs of the Hyæna remaining entire and not moved; which thing, they say, happens to the feathers of other birds if any one chance to tie them up in a bundle with the Eagles. Let these suffice for some few examples of many, of the Antipathy amongst beasts. But of the Sympathy and consent of beasts amongst themselves, I think needless to write any thing, being it is sufficiently known to all, that one Jay associates another, and the cruel Bears agree amongst themselves; and beasts of the same species do wonderfully consent one with another.

How to make
cheese that
Mice will not
gnaw.

That Man excels all beasts.

I Now think it fit to assay to write of that excellency of man over beasts, which I have so long intended. Neither would I that Epicures and other too much naturall and material Philosphers, so take those things I have written of the endowments of beasts, as though we should think, there were no difference between man and beast. I had no such meaning, no such intention; but only that man should not become too stately, or too ingrate in less acknowledging God to be the Author of so many benefits with which he abounds. For whatsoever we have largely spoken of beasts, yet there is no comparison between beasts and man, for there is too great a difference between them. For mans mind is adorned with religion, justice, prudence, magnanimity, faith, piety, modesty, clemency, fortitude, and other vertues as lights, which shine much more bright in man than in beasts. For they are sometimes all in some one man, each whereof are thought great in beasts. For seeing that man is made to the Image of God, it cannot be, how much soever he defile himself with the pollution of vices, that he can so obscure that inbred light, but that alwaies some beam of the divine wisdom will be inherent & shine in him. But although by collation to some beasts, he may seem a defective and weak Creature; yet no fortitude nor strength of beasts can be so great as to equal the fortitude of man. For God hath ingraven in man the character of his divine vertue, by the assistance whereof, he might have all beasts under and obedient to him. And though by that we have formerly said, beasts may seem to have a certain shadow of reason, yet that small light is not fit for many and divers uses, but there is only given them so much providence, as should be sufficient for them and the preservation of their bodies. But men have reason given them to crop or gather the fruits of eternall life, (as *Lactantius* saith) whereby it comes to pass, that man only, amongst so many creatures, hath sense and understanding of divine things. Which *Cicero* thought to be known by that, because man only had a certain knowledg of God in his mind. Wherefore he was enriched by God with reason, speech and hands as helps for the performance of all his actions; moreover by his singular and almost divine wit he easily excels all brute beasts. For first, reason being his guide, he invented things necessary for life, fitly imposed names on the things invented besitting their natures, framed letters and Characters, invented all liberall Arts and handy-crafts, and found means to measure the Land and Sea. He hath observed and drawn into an Art the spaces of the Celestiall Globe, the distinctions of the Stars, the changes and orders of dayes and nights, of times and seasons, the rising and setting of Stars, and their power and effects over these lower bodies. Lastly, he records in writing to perpetuall memory that which concerns his own nature, or the nature of other things, the precepts and ordinances of life and manners: by which singular gift, we can now confer with *Socrates*, *Plato*, *Aristotle*, and other Philosphers of ancient times, as if they were living.

Mans bears
Gods image.

Man hath given
names to
things.

What benefit man hath by reason of his native nakedness and ignorance.

BUT as Mans body is by nature naked and unarmed, so is his mind like a smooth table in which nothing is painted, nothing graven; but for help of his nakedness he hath hands, and for supply of his ignorance, reason and speech. And by these three being as it were the ministers of infinite variety of things, he clothes and defends his body with all things needfull: and enriches his mind with the knowledg of Arts and Sciences. Now if he had certain weapons born with him, he should use them only; if he should be born skilfull in any Art, he would meddle with none else. Therefore because it was more expedient to use all sorts of weapons with the hand, and be skilfull in all Arts; therefore he must be born wanting and ignorant of all. *Aristotle* very wittily called the hand the instrument of instruments: in imitation of which speech, one may rightly affirm, that reason is the

Gal. cap. 4. lib. 1. de su partium.

As the hand is
the instrument
of instruments
so reason is
the art of arts.

Art

Art of Arts: for as the hand in worth exceeds the other instruments, because it can make, handle and fit them for use; so reason and speech, though names of no Art, yet comprehend and encrease all Arts. Therefore man seeing he hath his mind instructed by Art, that is, by reason; it is fit he should have his body defended with a weapon, or instrument, that is, the hand, which in agility and excellency should excell all other instruments. For so Man hath of his hands in stead of all weapons, which he may use in war and peace as the instruments of all Arts; he wants not the Bulls horns, the Boars tuskes, the horses hoofts, nor to conclude, any arms of any other Beast. For by the benefit of his hands he can handle other arms far more profitable and safe; as a Lance, Sword, Spear, halberd; but man also can use at some distance the bow, sling and handgun, when the horn and the hoof cannot be used but neer at hand. But some may say; A Lyon exceeds a man in swiftness of foot; what then? is man therefore inferiour to him? no, for by the means of his hands and the guidance of his reason he bridling and riding upon a horse, out runs the Lyon, and being victor follows him to and again as he himself pleases, or vanquished flies away, and from the horses back as from a tower wounds the Lyon with what weapons he pleases. To conclude, man is abundantly provided with means, to defend himself from the violence of all other beasts. For this purpose he doth not only harness himself as with brazen wals, but also makes ditches and Bulwarkes, he makes by the ministry of his hands all kind of weapons, weaves himself garments, casts into the water and draws forth nets to catch fish; and to conclude, he performs all things to his own contentment, and having that priviledge granted him by God, he rules over all the earth; all things which lye hid in the bowels of the earth, which go, or creep upon the earth, which swim in the Sea, and flie through the air, or are any where shut up in the compass of the skie, are in mans dominion.

Man under
God is the king
and Emperour
of the world.

How wonderfull God hath shewed himself in making man.

Gods Deity and providence hath principally shewed it self in the creation of man; neither his so admired light hath so shone in the production of other creatures, seeing that God would have them to live and have their being, only for mans sake, that they might serve him. Therefore man is, if we diligently consider all his endowments, a certain pattern and rule of the divine majesty and (if I may so say) Artifice. For being made to Gods image, he is as it were his coin, exceeding the capacity of all humane understanding. Which seemed a just reason to the ancient Philosophers, that he should be called *Microcosmos*, or a little world, because the particles of all things contained in the compass of heaven and earth, are contained in his mind and body, that in the mean time I may in silence pass over his soul more great and noble than the whole world.

Man is the end
of all mundane
things.

Man a little
world, yea al-
most a great
world.

Why Nature hath not given Man the faculty of presaging.

This seems the reason, that men by the instinct of nature do not foresee the future seasons & dispositions of the heaven & air; because, seeing they have received certain sparks of prudence from God, by whose care and guidance they are led to the knowledge of things by no deceitfull but certain judgment, being not obnoxious to the conditions and changes of times and seasons, as beasts are. Wherefore knowing all these airy changes to be placed under them, that is to say, their minds, according as occasion serves, and their minds desire, they give themselves to mirth when the air is wet, stormy and dark, and on the contrary, in a clear and fair season, to a sincere and grave meditation of things sublime and full of doubt. But beasts accommodating themselves to that disposition of the air which is present and at hand, are lively, or sad, not from any judgment as men, but according to the temper and complexion of their bodies following the inclinations of the air, and of the humors one while diffused, another while contracted. Neither ought we to blame man, because he can imitate the voice of beasts, but rather much commend him, that he can infinitely wrest and vary one thing, that is, his voice; for men can bark like Foxes and dogs; grunt like hogs; whet and grind their teeth like boars; roare like Lyons; bellow like bulls; neigh like horses; knock their teeth like Apes; howl like Wolves; bray like Asses; bleat like Goats and Sheep; mourn like Bears, Pigeons, and Turtles; keeke and gaggle like geese; hiss like Serpents; cry like Storks; caw like a Crow, and crow like Cock; clock like hens; chatter as Swallows and Pies; sing like Nightingales; croak like Frogs; imitate the singing of Wasps, and Humming of Bees; mew like Cats. The singing of Birds scarce seems to merit the name of Musick, compared to the harmony of men fitted and tuned with infinit variety of voices. For with this they possess the ears of Kings and Princes; provoke and temper their wrath, and carry mens minds beyond themselves, and transforme them into what habits they please. But if those cruell beasts have any humanity, they owe it all to man. For he tames Lyons, Elephants, Bears, Tigers, Leopards, Panthers, and such other like.

Man is not
obnoxious to
the air and
stars.

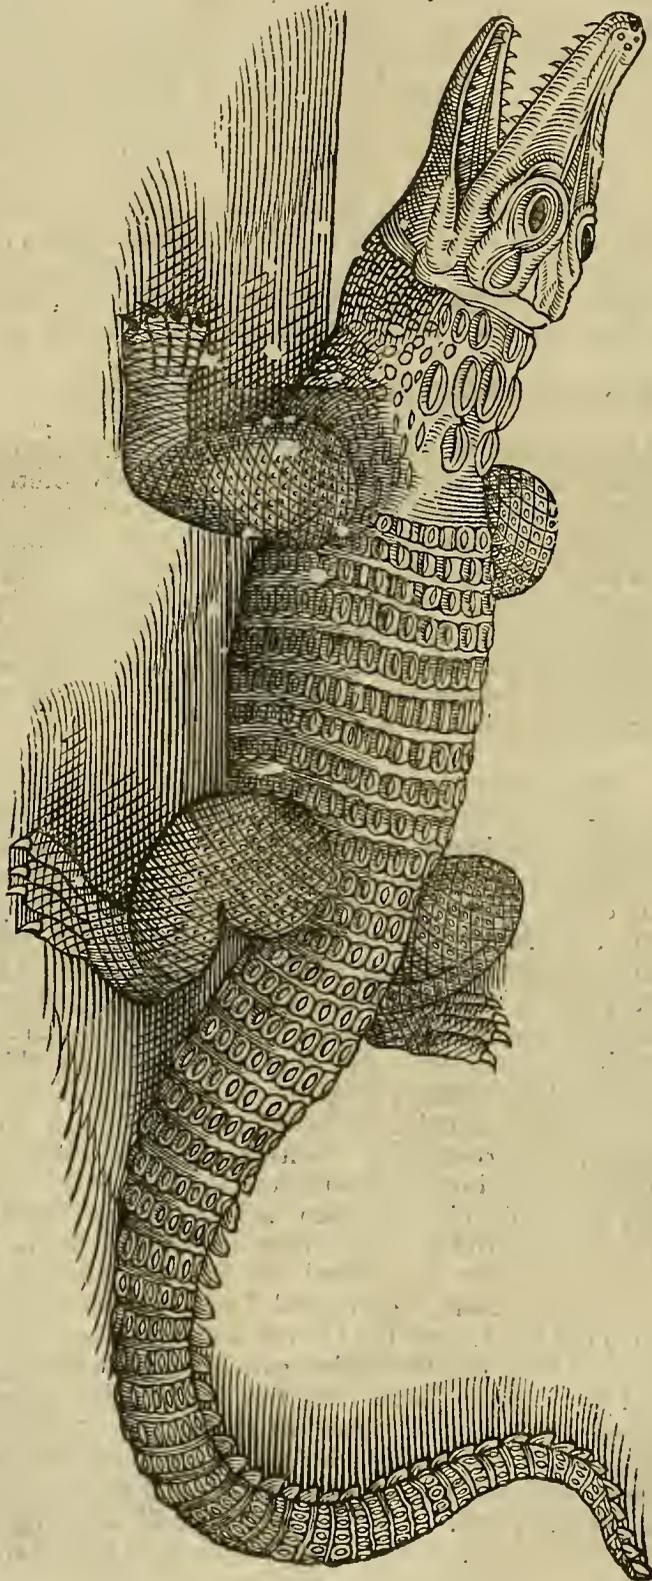

One man will
counterfeit the
voices of infi-
nite varieties of
beasts.

The power of
Musick.

Of the Crocodile.

A tame Crocodile.

Plutarch reports of the Crocodile (whose figure is delineated) that being tamed, and taught by man, he doth not only hear mans voice, and answers to his call, but suffers himself to be handled, and opening his throat, lets his teeth be scratched and wiped with a towell. How small a part of Physick is that, which beasts are taught by nature? Certainly nothing in comparison of man, who by the study and practise of a few years can learn at his fingers ends all the parts of Physick: and practise them not only for his own, but also for the common good of all men. But why cannot beasts attain unto the know-

ledg of Physick so well as men? I think, because so great an Art as Physick is, cannot be attained unto by the dull capacities of Beasts.

But for that I have written of the Religion of Elephants, if I must speak according to the truth of the matter, we cannot say they worship God, or have any sense of the divine Majesty. For how can they have any knowledge of sublime things or of God, seeing they wholly following their food, know not how to meditate on celestial things? Now for that they behold and turn themselves to the Moon by night, and to the Sun in the morning, they do not that as worshipping, or for that they conceive any excellency or divinity in the Sun; but because nature so requiring and leading them, they feel their bodies to rejoice in that light, and their entralls and humors to move and stir them to it. Therefore when we attributed religion to Elephants, we said it rather popularly, than truly, and more that we might exhort men to the worship of God, than that we thought Elephants had any knowledg of divine worship implanted in their minds.

In what sense we said Elephants had religion.

That man may attain unto the knowledg of all voices and tongues.

THe docility of mans wit is so great, and facility of the body obeying that divine gift of wit such, that he is not only able to learn to understand and speak the tongues of divers nations differing in so many peculiar languages; and not only to imitate and counterfeit the voices of all beasts though so much different from man, which many flattering and juggling companions, followers of other mens tables, will do; but also may be able to know and understand both what they pretend and signifie. In confirmation of which thing they cite the Philosopher *Apollonius* most famous in this kind of study and knowledg. He walking on a time amongst a company of his friends through the field, and seeing a Sparrow come flying and chirping much to divers other Sparrows sitting upon a tree, is reported to have said to those which were with him: That bird which came flying hither, told the other in her language, that an Ass laded with corn was fallen down at the City gate, and had shed the wheat upon the ground. Wherefore *Apollonius* and all his friends which minds were with him went thither to see whether it were so, and found that it was so, as he had told them, and observed that the Sparrows moved thereto by the coming of the other, were eating up the grains of Corn shed on the ground.

Man not only the imitator, but the interpreter of the voices of beasts and birds.

But for Crows and Pies artificially taught to counterfeit mens voyces, it is too small a thing, that for that cause they should contend with men. For they have quickly babled all they have learnt with longer cost and labour, tediously singing still the same song, and whatsoever they prate they do it without sense, understanding or any reason for what they say. But man alwayes contemplating somewhat more high, still thinks of greater things than these present, and never rests. But burning with an infinite and endless desire of knowledg, he doth not only covet to know these things which appertain to food and cloathing, but by casting up his eyes towards heaven, and by the light of his mind, he learns and understands things divine. Which is so certain an argument of the celestiall originall of our soul, that he which considers those things can no wayes doubt, but that we have our minds seasoned, by the universall divine understanding. But now it is time for us to set thait upon the description of the body, the habitation and fit instrument of al the functions of divne mind.

The unquerable desire of learning in man.

The End of the second Book.

The third Book,

TREATING

Of the Anatomy of *MANS BODY*.

Following the custom and the manner of such as before me have written of Anatomy, will first, (that I may make the minds of the Readers more attentive and desirous of these studies) declare how necessary it is, and also how profitable, and then shew the order to be observed in it, before I come to the particular description of mans body.

Furthermore how Anatomy may be defined, and the manner of the definition of the parts. For the first, the knowledg of Anatomy seems in my judgment very necessary to those that desire to excell, or attain to perfection of Physick; that is, whereby they may be able to preserve the present health of the body, and the parts thereof, and drive away diseases. For how can either Physitian or Chirurgion preserve health by the use of the like things, which consists in the temperament, conformation, and naturall union of the parts; or expell the disease which hurts those three, by the like use of their contraries, unless he shall know the nature and composure of the body, and understand as by the rule of this knowledg, how much it swerves from the nature thereof? Wherefore it is excellently said of *Hippocrates*; that the Physitian called to cure the sick Patient, ought diligently to consider, whether those things that are in him, or appear to be in him, be like or unlike, that is, whether the Patient be like himself and his own nature in all his parts and functions, temperature, composure and union; that he may preserve those which are yet contained in the bounds of nature, and restore those that are gone astray. Which thing *Galen* hath also confirmed, specially where he saith, he must well know the nature and structure or composure of the bones, who takes upon him to restore them broken or dislocated to themselves and their proper seats or places. Moreover seeing that healing doth not only consist in the knowledg of the disease, but as well in prescribing fit medicines and like application of them to the body and the parts thereof, all which by their naturall dissimilitude, do require unlike medicines, according to *Galen*'s opinion:

I prethe tell mee, who can perform this, which is ignorant of the description of the whole and the parts thereof, taught by Anatomy? We may say the like of the Apothecary, who ignorant of the situation of the parts in the body cannot apply Emplaisters, Ointments, Cataplasms, Fomentations, Epithemes, bags to the fit places, as to the futures of the skull, to the Heart, Liver, Stomach, Spleen, Reins, Wombe or Bladder. For example, let us imagine the Liver to be troubled with a hot distemperature, but on the contrary, the stomach with a cold (which commonly happens, seeing the Liver hotter than it ought to be, sends up many vapours to the head, from whence cold humors fall into the stomach) if hot things to be applied to the stomach by the Physitians prescription, be by the Apothecary making no difference, applied both to the stomach and neighboring Liver (which may chance if he be ignorant that the stomach bends somewhat to the left side under the breast-blade; but the liver so takes up the right side of the body that with a great part thereof, it covers almost all the stomach) will not he much offend by increasing the hot distemper of the liver, and not thereby giving ease, or help to the disease? Shall not by this his ignorance, the Patient be frustrated of his desire, the Physitian of his intent, and the medicine of its effect? By these examples I think it most manifest, that the Anatomical knowledg of the parts of the body is exceeding necessary to all Physitians, Chirurgions, and Apothecaries, who will practise Physick with any praise to the glory of God, and the benefit and good of man, for whose sake we have writ these things, and illustrated them by figures, subjecting the parts to the eye, and fitly put them in their proper places.

But Anatomy is commodious four manner of wayes; the first is, because thus we are led to the knowledg of God the Creator, as by the effect to the cause; for as we read in *St. Paul*, The invisible things of God are made manifest by the visible. The second is, that by means hereof we know the nature of mans body, and the parts thereof, whereby we may more easily and certainly judg and determine of sickness and health. The third is, that by the knowledg of the body and its parts, and together therewith its affections and diseases, we may prognosticate what is to come, and foretell the events of diseases. Lastly, the fourth is, that considering the nature of the diseased part, we may fitly prescribe medicines, and apply them in their due places.

Now we must declare in what order Anatomy may be fitly delivered; but first we must observe there is a threefold Method; The first is called of Composition, being very commodious for the teaching of Arts, which *Aristotle* hath used in his Works of Logick, and naturall Philosophy, the order and beginning taken from the least and most simple to the more compound. The second of Division, fit for the inventing or finding out of sciences. *Galen* hath followed this order in his Books of Anatomical Administrations, and

The necessity of the knowledg of Anatomy.

Initio lib. de Offic. medici.

Lib. de ossibus.

I. de loc. affectus, & lib. 3. Meth.

Why when the liver is hot the stomach is commonly cold.

The Knowledg of Anatomy, is commodious four manner of wayes.

There is a threefold method.

and of the use of the parts. The third of Definition, which sheweth the nature and essence of things, as appears by *Galen* in his Book *De Arte Parva*. And because this order doth also prosecute the divisions, therefore it is commonly accustomed to be comprehended in the compass of the second. Therefore I will follow this in my Anatomical Treatise, dividing mans body into its parts, which I will not only subject to the eye in the way of knowing them, but also to the mind in the faithfull understanding them. For I will adjoyn those things that are delivered of them by *Galen* in his Book of Anatomy. Administrations, with those which he hath taught in his Books of the use of the parts. For there he fitly laies the parts of mans body before our eyes, to the sense. But here he teaches to know them, not to see them; for he shews why, and for what use they are made. Having briefly handled these things, we must declare what Anatomy is; that as *Cicero* saith out of *Plato's Phædro*, it may be understood of what we dispute. And because we attain that by definition (which is a short and plain speech, consisting of the *Genus* and difference of the things defined, being the essential parts, by which the nature and essence of the thing, is briefly and plainly explained) first we define Anatomy, then presently explain the particular parts of the definition.

The Authors intent.

Wherefore Anatomy, (if you have regard to the name) is a perfect and absolute division, or artificial resolution of mans body into its parts, as well generall as particular, as well compound as simple. Neither may this definition seem illegitimate, specially amongst Physicians and Chirurgeons. For seeing they are Artizans humiliated to the sense, they may use the proper and common qualities of things for their essential differences and forms. As on the contrary, Philosophers may refuse all definitions as spurious, which consist not of the next *Genus* and the most proper, and essential differences. But seeing that, through the imbecillity of our understanding, such differences are unknown to us, in their places we are compelled in defining things, to draw into one many common and proper accidents, to finish that definition which we intend, which for that cause we may more truly call a description, because for the matter and essential form of the thing, it presents us only the matter adorned with certain accidents. This appears by the former definition, in which *Division* and *Resolution* stand for the *Genus*, because they may be parted into divers others, as it were into *species*. That which is added over and besides, stands in place of the difference, because they separate and make different the thing it self from all other rash and unartificial dissections. We must know an artificial division, is no other than a separation of one part from another, without the hurt of the other, observing the proper circumscription of each of them; which if they perish or be defaced by the division, it cannot be said to be artificial; and thus much may suffice for the parts of the definition in generall.

What Anatomy is.

How a definition differs from a description.

For as much as belongs to the explication of each word; we said of *Mans body*, because as much as lies in us, we take care of, preserve the health, and depell the diseases thereof, by which it may appear that mans body is the subject of Physick, not as it is mans, or consists of matter and form, but as it is partaker of health and sickness.

The subject of Physick.

We understand nothing else by a part, according to *Galen*, than some certain body, which is not wholly disjoined, nor wholly united with other bodies of their kinds; but so that, according to his opinion, the whole being composed therewith, with which in some sort it is united, and in some kind separated from the same, by their proper circumscription. Furthermore by the *parts in generall*, I understand the head, breast, belly, and their adjuncts. By the particular parts of those, I understand, the simple parts, as the similar, which are nine in number, as a gristle, bone, ligament, membrane, tendon, nerve, vein, arterie, musculous flesh; some add fibers, fat, marrow, the nails and hairs; other omit them as excrements; but we must note that such parts are called simple, rather in the judgment of the sense, than of reason. For if any will more diligently consider their nature, they find shall none absolutely simple, because they are nourished, have life and sense, either manifest or obscure, which happens not without a nerve, vein, and artery.

Gal. lib. I. de usus part. lib. I. Metb.

The similar parts are nine.

But if any shall object, that no nerve is communicated to any bone, except the teeth; I will answer, that nevertheless the bones have sense by the nervous fibers, which are communicated to them by the *Periosteum*, as by whose mediation the *Periosteum* is connext to the bones, as we see it happens to these membranes, which involve the bowels. And the bones, by this benefit of the animall sense expell the noxious and excrementitious humors from themselves into the spaces between them and the *Periosteum*, which as indued with a more quick sense, admonisheth us, according to its office and duty, of that danger which is ready to seise upon the bones, unless it be prevented. Wherefore we will conclude according to the truth of the thing, that there is no part in our body simple, but only some are so named and thought, according to the sense; although also otherwise some may be truly named simple, as according to the peculiar and proper flesh of each of their kinds. Those parts are called compound which are made or composed by the mediation, or immediately of these simple, which they term otherwise organically, or instrumentally; as an arm, leg, hand, foot, and others of this kind.

How the bones come to feel.

The compound, or organical parts.

And here we must observe, that the parts are called simple and similar, because they cannot be divided into any particles but of the same kind; but the compound are called

Four particles
to be observed
in each organ-
icall part.

dissimilar from the quite contrary reason. They are called instrumentall and organically, because they can perform such actions of themselves, as serve for the preservation of themselves and the whole; as the eye of it self, without the assistance of any other part, seeth, and by this faculty defends the whole body, as also it self. Wherefore it is called an instrument or organ, but not any part of it, as the coats, which cannot of it self perform that act. Whereby we must understand, that in each instrumentall part we must diligently observe four proper parts. One by which the action is properly performed, as the Crystalline humor in the eye; another without which the action cannot be performed, as the nerve and the other humors of the eye. The third, whereby the action is better and more conveniently done, as the tunicles and muscles. The fourth, by which the action is preserved, as the eye-lids and circle of the eye. The same may be said of the hand, which is the proper instrument of holding; for it performs this action, first, by the muscle, as the principall part; Secondly, by the ligament, as a part without which such action cannot be performed; Thirdly, by the bones and nails, because by the benefit of these parts, the action is more happily performed; Fourthly, by the veins, arteries and skin, for that by their benefit and use, the rest, and so consequently the action it self is preserved.

Four sorts of
instrumentall
part.s.

But we must consider, that the instrumentall parts have a fourfold order. They are said to be of the first order, which are first and immediately composed of the simple, as only the authors of some one action, of which kinds are the muscles and vessels. They are of a second which consist of these first simple, and others besides, as the fingers. They are counted of the third rank, which are composed of parts of the second order and some besides, as the hand taken in generall. The fourth order is the most composed, as the whole body, the organ and instrument of the soul. But you must observe, that when we say the muscles and vessels are simple parts, we refer you to the sense and sight, and to the understanding, comparatively to the parts which are more compound; but if any consider their essence and constitution, he shall understand they are truly compound, as we said before. Now it remains, that we understand, that in each part, whether simple or compound, nine things are to be considered, as substance, quantity or magnitude, figure, composition, number, connexion, (by which name, we also understand the originall and insertion) temperature, action, and use; that by the consideration of these things, every one may exercise the art of Physick, in preserving health, curing diseases, or foreseeing their events and ends.

Nine things to
be considered in
each part.

Why the three
principall
parts are so
called.

But also we must note, that of the organically parts, there be three, by whose power the body is governed; which for that cause they call regent and principall, because they govern all the rest; they are the liver, heart, and brain. But they are called principall, not only, because they are necessary for life, (for the stomach, wind-pipe, lungs, reins, bladder, and such like parts perhaps are equally as necessary for life) but because from each of these three, some force, power, and faculty, or also matter necessary for the whole body, flow over all the body, when no such thing proceeds from the rest of the parts. For from the liver a matter fit for nourishment, is distributed by the veins through all the body; from the heart the vitall force diffused by the arteries, imparts life to the whole body; from the brain by the nerves a power or faculty is carried through all the parts of the body, which gives them sense and motion.

Lib. de Arte me-
dica.

Galen would have the Testicles to be of this kind, not for the necessity of the individual, or peculiar body, but for the preservation of the *Species* or kind. And moreover in his book *de Semine* comparing the Testicles with the Heart, hee makes them the more noble by this reason, that by how much it is better to live well and happily, than simply and absolutely to live, by so much the testicles are more excellent than the heart, because with them we may live well & pleasantly, but with this simply live, as we see by the example of Eunuches, and such as are gelt, by which the Testicles seem rightly to be accounted amongst the principall parts; for nature seeing it desired, that this its work should be immortal, for the attaining of that immortality which it intends, frames those parts, like as prudent founders of a City, who do not only procure to furnish their City with many Inhabitants, so long as they are in building it, but also that it may remain in the same state and condition for ever, or at least for many ages. And yet notwithstanding of so many cities built in the first memory of man, there remains none, whose fame and state, together with the builders name, is not decayed and perished. But this humane work of nature, stands yet secure for this many thousand of years, and shall endure hereafter, because it hath found a way, by which every one may substitute another in his place before he depart. Hence it is that all creatures have members fit for generation, and pleasures inserted in those members, by which they might be inticed to mutuall embraces and copulations. But the mind, which hath dominion over those members hath an incredible desire of propagating the issue, by which also brute beasts inticed, desire to propagate their kinds for ever. For seeing that nature understands all these her works considered particularly by themselves, are frail and mortall, it hath done what it could to recompence that fatall necessity of dying, by a perpetuall succession of individualls.

The use and
function of
the parts ser-
ving for gene-
ration.

Hitherto we may seem to have abundantly shewed what necessity of knowledg in Anatomy belongs to all Artizans in Physick, and also what order is to be observed in the same.

same. And lastly, how it is defined, and the reason of the parts of the definition. Wherefore it remains that we prosecute what we have taken in hand: which is, that we shew and declare how to know all and every the parts of mans body, how many, and what they be, and to understand wherefore they be. For although the true knowledg of Anatomy may be perfected by the sight of the ey, and touching and handling each part with the hand; yet nevertheless the labor of describing Anatomy is not unprofitable. For by reading, such as have often exercised themselves in the dissecting of mens bodies, may refresh and help their memories, and such as have not, may make plain and easie the way to the understanding of dissections.

C H A P. I.

The division or partition of mans Body.

BY reason the partition of Mans body can hardly be understood, if the distinction of the proper faculties of the soul be not understood, for whose cause the body enjoys that form (which we see) and division into divers instruments; Therefore I thought good in few words to touch that distinction of the faculties of the soul, for the better understanding of the partition of the body which we intend. Wherefore the soul, the perfection of the body, and beginning of all its functions, is commonly distinguished, and that in the first and generall division, into three faculties, which are the Animall, Vitall, and Naturall. But the Animall is divided into the principall, sensitive, and motive; Again the Principall is distinguished into the imaginative, reasonable, and memorative: And the Sensitive into seeing, hearing, smelling, tasting, and touching: But the Motive into progressive and apprehensive. And the Vitall is divided into the dilative and contractive faculty of the heart and arteries, which we know or understand by the pulsfick faculty. But the Naturall is parted into the nutritive, auctive, and generative faculties; which three perform their parts by the help and ministry of five other faculties, which are, the attractive, retentive, concoctive, assimilative, and expulsive.

After the self-same manner, the organ or instrument of the soul, to wit, Mans body, at the first division is distinguished into three parts, which from their office they call Animall, Vitall, and Naturall. These again, according to the subdivision of the subalternall faculties, are divided particularly into other parts; so that any one may know the organ of each faculty, by the property of the function. For while other Anatomists divide mans body into four universall and chief parts, they distinguish from the three first, those which they call the Extremities; neither do they teach to what rank of the three prime parts each extremity should be reduced. From whence many difficulties happen in reading the writings of Anatomists; for shunning whereof, we will prosecute, as we have said, that distinction of mans body, which we have touched before.

Wherefore, as we said before, mans body is divided into three principall and generall parts, Animall, Vitall, and Naturall. By the Animall parts, we understand not only the parts pertaining to the head, which are bounded with the crown of the head, the collar-bones, and the first *Vertebra* of the breast, but also the extremities, because they are organs and instruments of the motive faculty; *Hippocrates* seems to have confirmed the same, where he writes; Those who have a thick and great head, have also great bones, nerves, and limbs. And in another place he saith, those who have great heads, and when they stoop shew a long neck, such have all their parts large, but chiefly the Animall. Not for that *Hippocrates* would therefore have the head the beginning and cause of the magnitude and greatness of the bones and the rest of the members; but that he might shew the equality and private care or government of nature, being most just and exact in the fabrick of mans body, as if she hath well framed the head, it should not be unlike that she idly or carelessly neglected the other parts which are less seen. I thought good to dilate this passage, lest any might abuse that authority of *Hippocrates*, and gather from thence, that not only the bones, membranes, ligaments, grilles, and all the other animall parts, but also the veins and arteries depend on the head as the originall. But if any observe this our distinction of the parts of the body, he will understand we have a far other meaning.

By the Vitall parts, we understand only the heart, arteries, lungs, winde-pipe, and other particles annexed to these. But by the Naturall, we would have all those parts understood which are contained in the whole compass of the *Peritoneum* or Rim of the body, and the processes of the *Erythroides*, the second coat of the Testicles. For as much as belongs to all the other parts, which we call containing; they must be reckoned in the number of the Animall, which notwithstanding, we must thus divide into principall, sensitive, and motive; and again, each of these in the manner following. For first, the principall is divided into the imaginative, which is the first and upper part of the brain, with its two ventricles and other annexed particles; into the reasoning, which is a part of the brain, lying under the former, and (as it were) the top thereof with its third ventricle; into the memorative, which is the *cerebellum* or afterbrain, with a ventricle hollowed in its substance. Secondly, the Sensitive is parted into the visive, which is in the eyes; the auditive, in

What the soul is, and with how many faculties it is endued.

All the parts of mans body are distinguished into three.

What parts are here called Animall.

Lib. 6 Epidem.

What parts are called Vitall.

The division of the animall parts.

the ears; the smelling, in the nose; the tasting, in the tongue and palate; the tactile, or touching which is in the body, but most exquisite in the skin which invests the palms of the hands. Thirdly, the motive is divided into the progressive, which intimates the legs, and the comprehensive, which intimates the hands. Lastly, into simply motive, which are three parts, called bellies, for the greatest part terminating and containing; for the vitall, the instrument of the faculty of the heart, and dilatation of the arteries, are the direct or streight fibers, but of the constrictive the transverse; but the three kinds of fibers together, of the pulfick; or if you please you may divide them into parts serving for respiration, as are the lungs, and weazon, and parts serving for vitall motion, as are the heart and arteries, furnished with these fibers, which we formerly mentioned. The division of the naturall parts remains, which is into the nourishing, auctive and generative, which again are distributed into attractive, universall, and particular; retentive, concoctive, distributive, assimilative, and expulsive. The attractive, as the gullet and upper orifice of the ventricle; the retentive, as the *Pylorus* or lower passage of the stomach; the concoctive, as the body of the ventricle, or its inner coat; the distributive, as the three small guts; the expulsive, as the three great guts; we may say the same of the liver, for that draws by the mesaraick and gate veins, retains by the narrow orifices of the veins dispersed through the substance thereof; it concocts by its proper flesh; distributes by the hollow vein, expels by the spleen, bladder of the gall and kidnies. We also see the parts in the testicles divided into as many functions; for they draw by the preparing vessels; retain by the various crooked passages; in the same vessels they concoct the seed by the power of their proper substance and faculty; they distribute by the ejaculatory, at the glandules called *Prostate*, and the horns of the wombe, supplying the place of prostates; Lastly, they expell or cast forth by the prostates, horns, and adjoining parts. For as much as belongs to the particular attraction, retention, concoction, distribution, assimilation of each part, that depends of the particular temper, and as they term it, occult property of each similar and simple part. Neither do these particular actions differ from the universall, but that the generall are performed by the assistance of the three sorts of fibers, but the special by the severall occult property of their flesh, arising from their temperature, which we may call a specifick property. Now in the composition of mans body, nature principally aims at three things. The first is, to create parts necessary for life, as are the heart, brain, and liver. The second, to bring forth other for the better & more commodious living, as the eyes, nose, ears, arms and hands. The third is, for the propagation and renewing the *species* or kind, as the privie parts, testicles, and wombe. And this is my opinion, of the true distinction of mans body, furnished with so many parts, for the performance of so many faculties; which you, if you please, may approve of and follow. If not, you may follow the common and vulgar, which is, into three bellies, or capacities, the upper, middle, lower, (that is, the head, brest and lower belly) and the limbs or joints. In which by the head we do not understand all the Animall parts, but only those which are from the crown of the head to the first *vertebra* of the neck, or to the first of the back, if according to the opinion of *Galen*, *Lib. de ossibus*, where he makes mention of *Enarthrosis* and *Arthrodia*, we reckon the neck amongst the parts of the head. By the brest, whatsoever is contained from the collar bones to the ends of the true and bastard, or short ribs, and the midriffe. By the lower belly, the rest of the trunck of the body, from the ends of the ribs to the share-bones; by the limbs, we understand the arms and legs. We will follow this division in this our Anatomical discourse, because we cannot follow the former in dissecting the parts of mans body, by reason the Animall parts are mutually mixed with the vitall and naturall, and first of the lower belly.

The division of the vitall parts.

The division of the naturall parts.

The vulgar division of mans body.

Why the belly is not bony.

Nature would not have this lower belly bony, because the ventricle might be more easily dilated by meat and drink, children might grow the better, and the body be more flexible. It is convenient we begin our Anatomical administration from this, because it is more subject to putrefaction than the rest, both by reason of its cold and moist temperature, as also by reason of the feculent excrements therein contained. Yet before we go any further, if the Anatomical administration must be performed in publick, the body being first handsomely placed, and all the instruments necessary for dissection made ready, the belly must be divided into its parts, of which some contain, and other some are contained.

The division of the lower belly.

They are called containing, which make all that capacity which is terminated by the *Peritoneum* or Rim of the belly. The upper part whereof is bounded by *Galen* within the compass of the direct muscles, and by a generall name is called *Epigastrium*, or the upper part of the lower belly. That again is divided into three parts, that is, into that which is above the navil, and which carries the name of the whole, into that which is about the navil, and is called the umbilicall or middle part; and lastly, into that which is below the navil, called the *Hypogastrium*, or the lower part of the lower belly.

The *Hypochondria*.

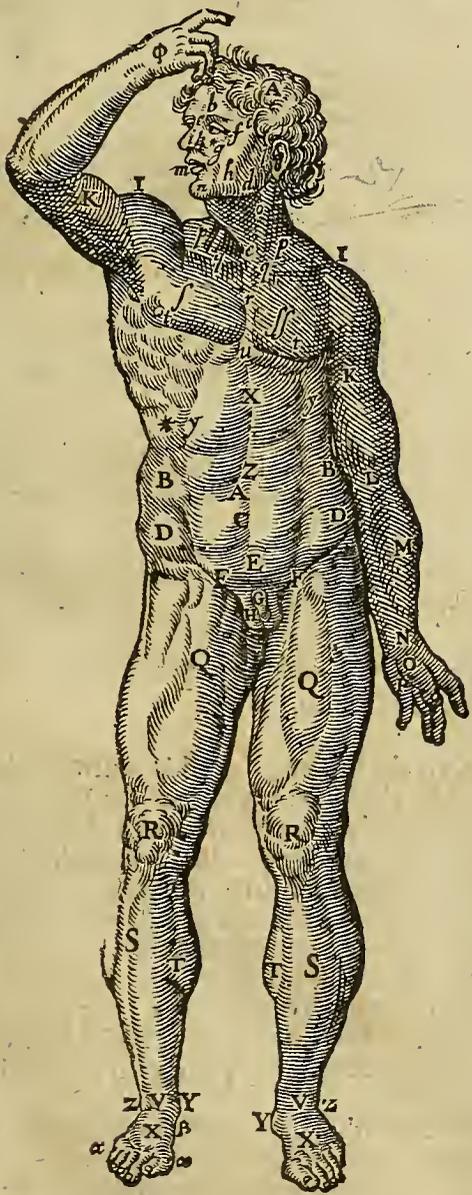

In every of which three parts there be two laterall, or side parts to be considered, as in the *Epigastrium*, the right and left *Hypochondria*, which are bounded above and below, in the compass of the midriffe, and the short ribs. In the umbilicall the two *Lumbares* (some call them *Laterales*) which on both sides from the lowest parts of the brest, are drawn to the flanks or hanch-bones; in the *Hypogastrium*, the two *Iliæ*, or flanks, bounded with

with the hanch and share-bones. Neither am I ignorant, the *Ilia*, or flanks, which the Greeks call *καυός* signifie all the empty parts, from the ends of the ribs, even to the hanch-bones, whereupon they also call them *Κεῖρα*, as if you should say empty spaces, because they are not encompassed with any bone. Yet I thought good that this doctrine of dividing the belly should be more distinct, to call the parts which are on each side the navell *Lumbares*, and those on the lower part of the lower belly *Ilia*, flanks. But we must observe that the Ancients have been so diligent in deciphering the containing parts, that as exactly as might be, they designed the bowells contained in the belly, which being divers lie in sundry places; for the greater portion of the liver lies under the right *Hypochondrium*; under the left almost all the ventricle and spleen. Under the *Epigastrium* the lower orifice of the ventricle, and the smaller portion of the liver; In the *Lumbares*, or sides, in the right and upper part the right kidney, in the lower part towards the flank, the blind gut; in the middle part thereof the colick and empty guts. In the upper part of the left side lies the left Kidney, in the middle part, the rest of the empty and colick guts. Under the region of the navell, lies the girdle or upper part of the kall, the colick gut thrusting it self also through that way. Under the *Ilia*, or flanks, the right and left, lie the greater part of the guttleon, the horns of the women big with child, and the spermatick vessels in men and women. Under the *Hypogastrium* in the lower part lies the right, or strait gut, the bladder, womb, and the rest of the kal.

If we know, and well understand these things, we shall more easily discern the parts affected by the place of the pain, and cure it by fit application of remedies, without the hurting of any part. The distinction of such places, and the parts in those places, as seeming most profitable, I have thought good to illustrate by the placing these two following figures, in which thou hast deciphered, not only the foresaid parts, containing, and contained, but also of the whole body, and many other things which may seem to conduce to the knowldge of the mentioned parts. The Figures are these.

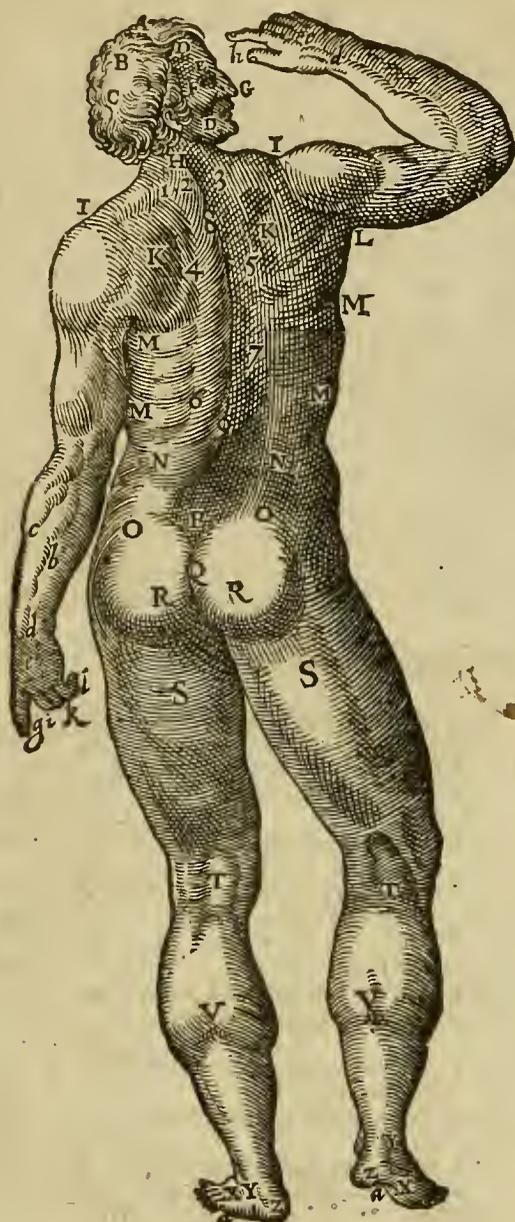

A most certain note of the part affected by the place where the pain is.

The Figure shewing the foreparts of the body.

- A The hairy Scalp, cald *τὸ χωρὸς*.
- b the forehead cald *Φrons μέτωπον*.
- c the temples cald *tempora, κέφαλος*.
- From b to d The compass of the face.
- e The greater or inward corner of the eyes, cald *Canthus internus*.
- f The lesser or external angle of the eye, cald *Canthus externus*.
- * The lower eyebrow which is immovable, *Palpebra*.
- g The cheek-bal cald *μαλα, μύλα*.
- b The cheek-puf cald *bucca, γυζ*.
- i The ridg of the nose cald *Nasus externus, γιν*.
- k The nothriils cald *nares, μύκων*.
- l The outward ear, *auris externa*.
- m The mouth made of the two lips, *Os*.
- n The chin called *mentum, γίνεον*.
- o The n.ck, *collum, ἀνυχὴν* and *πλάχιλον*.
- From o to e the pillar of the neck, *vinculus* and *ἄλμη*.
- pp The hollow of the neck, called *juguli, σφαγάτι*.
- qq The pael bones, *claves, κλάβες*.
- r The chest, *pectus, στήθον*.
- f The right brest.
- ff The left brest: to this Region we apply cordiall *Epithemation* moist and dry.
- ii The nipples of the brests, *papille, θηλάδον*.
- u The trench of the heart which the Ancient called *καρδία*. The Latines *scrobiculus Cordis*. This part is anointed for the mouth of the stomach
- From u. to e the lower belly, *γαστήρ*.
- X The *Epigastrium* or upper part of the lower belly.
- yy The *Hypochondria* or *Pracordia*.
- * The outward Liver-remedies are applied to this place.
- z The region of the navill, called *umbilicalis*, or the middle part of the lower belly.
- BB. The side *Latera, πλευράς*. and in our Author *Lumbi seu Lumbaris regio*.
- C. *Hypogastrium*; the water-course, *Aquaticulus*, the lower part of the lower belly, *ἠέσπον*.
- DD. The flanks called *Ilia*, and *κνεσῶνες*.
- E. The Groin called *pubes* or *πέπτεν, κείεις, κείβη*.
- FF. The Leske cald *inguen* where those tumors are cald *Bubones*.
- G. The yard with the fore-skin; *penis cum praputio*.
- H. The stones or testicles, with the cod or *scrotum*.
- II. The shoulders, *lumeri, ἐπιπλάδες*.
- KK. The arms *Brachia, βραχίονα*.
- L. The bowt of the arm, called *Gibber, ἀγκών*.
- M. The outside of the lower part of the arm called *cubitus, πῆχυς*.
- N. The wrist called *Brachiale, κέρκος*.
- O. The after wrist *postbrachiale, μέσαστρονον*.
- P. The Palm called *Palma* or *vola manus, βένας*.
- φ The back of the hand, *Dorsum manus, ὄμη*. *δένας*.
- QQ. The fore and middle part of the thigh, where we apply cupping-glasses to bring down womens courses *μυρσόν*.
- RR. The knee, *genu, γόνυ*.
- SS. The leg, *tibia, κνήμη*.
- TT. The calf of the leg, *surus, γαστρονήμων*.
- VV. The instep, *plantis*.
- XX. The top of the foot, *Dorsum pedis, ἠέσπον*. *ποδός*.
- YY. The inner Anckles, *σφυρῶδ*.
- ZZ. The outward anckles, *αα* the toes of the feet, *β* the place under the inward ankle, where the vein called *Saphena* is opened.

The figure of the back-parts of a Man.

- A. The forepart of the head, *σινειριτι*, *βρεγμα*.
 B the top or crown of the head, *veritex*, *κορυφη*.
 C. the hinder-part of the head, *occiput*, *κοτις και ινιδν*.
 From D. to D. the face, *facies*, *ωροσωπον*.
 * E. the eyebrows, *supercilia*, *οφρυς*.
 F. the upper eyelid, *ελεφαρον*.
 G. the tip of the nose, called *globulus nasi*.
 H. the back-part of the neck, called *cervix*, *αυχην*, and the nape or nape of the neck. There is a hollowness at the top of this *cervix*, where we apply Seaton.
 I. the back part of the shoulder top, called *axilla*, *ωμυ*.
 KK. the shoulder blades, *scapula*, *ωμοπλατα*.
 1, 2, 3. On this place we set Cupping-glasses.
 4, 5, 6, 7. the back, *dorsum*, *ωσπον*.
 8, 9. the ridge, *spina dors*, *ραχιδ*.
 L. the armpole, *ala*, *μαχαλη*.
 * The elbow, *gibber brachii*.
 M M M M. the sides, *latera*.
 NN. the loins, *lumbi*, or the region of the kidneys, *οσφρες*.
 O O. the place of the hips, *coxendices*, where we apply remedies for the Sciatica.
 P. the place of the Holy bone, or *Os sacrum*, where we apply remedies in the diseases of the right gut.
 Q. the place of the rump or *Coccyx*.
 R R. the buttocks, *nates*, *χλιδες*.
 S S. the back parts of the thigh, *femora*.
 T T. the ham, *poples*, *εχιδες*.
 V V. the calf of the leg, *sura*.
 X X. the foot, or *parvus pes*, *πους*.
 Y Y. the utter ankle, *malleolus externus*.
 Z Z. the heel, *calc*, or *calcaneus*, *πτερον*.
 a a. the sole of the foot, *planta pedis*, *κοilon τε ποδης*.
 b. the inside of the lower part of the arm, called *ulna*, *ωλενη*.
 c. the ou side of the same, *cubium*, *πυχς*.
 d d. the wrist, *carpus*.
 e e. the back-part of the hand, *dorsum manus*, g. the forefinger, *index*, *δειχαι*. h. the thumb, *pollex*, *αντιχειρ*.
 i. the middle finger, *medius*, *μεσο*.
 k. the ring finger, *annularis*, *medicus*, *ιατρικος*.
 l. the little finger, *auricularis*, *minimus*, *ωπιτης*.

C H A P. II.

Of the containing parts of the Epigastrium, and the preparation to Anatomical administration.

The containing parts of the lower belly.

The containing parts of the *Epigastrium*, are the *Epidermis*, or thin outward skin; the true skin; the fleshy or fatty Pannicle; the eight muscles of the *Epigastrium*, with their common coat; the Rim of the belly; the five vertebra's of the loins; all the holy-bone; the hanch-bone; share-bone; the white line and midriff. Of these parts, some are common to the whole body, as the three first; the other proper to the parts contained in the *Epigastrium* taken in generall. Which that you may see in their order, first you must cut round about the navell, to the upper superficies of the muscles, that so we may keep it, till such time, as occasion shall offer it self, to shew the umbilicall vessels lying in that place, which are one vein, two arteries, and the *Utrachus* (if it be there.) Which being done, you must draw a streight line from the chest, over the brest-blade, even to the share-bone, which may divide the common-containing parts, even to the white line.

Then presently it will be convenient to draw two other lines across or overthwart, of the like depth on each hand, from the circumference of the navell, even to the sides, that so on each part we may draw the skin more commodiously from the parts lying under it; the sight of which otherwise it would hinder. These things being done, the skin must be

be divided from the parts lying under it from the designed circumference left about the navell. We must teach how the skin is twofold, the true and false, and render a reason of the name, which we will every where do, as far as the thing will suffer, and it shall lye in our power. And in doing or examining these things, it will be convenient diligently to enquire into the nine things mentioned in the Preface. We will begin with the Skin, because that part is first obvious to our senses.

C H A P. III.

Of the utmost Skin or Cuticle.

The skin being the first part, and spread over all the body, is twofold, that is, the true and bastard skin: The true is called by the Greeks, *Derma*, which may almost every where be pulled from the parts lying under it, which it invests; except in the face, ears, the palms of the hands, soles of the feet, fingers, and privities, where it sticks so close that it cannot be separated.

The skin twofold
From what parts the skin cannot be separated.

The bastard (which first of all we will declare, because it first presents it self to our sight) is by the Greeks called *Epidermis*, because it covers the true skin, they term it commonly the Cuticle. The substance of it is excrementitious, and (as it were) a certain dry flouring, or production of the true skin. That it draws not its substance from the seed is apparent by this, that as it is easily lost, so it is easily repaired, which happens not in parts truly spermaticall. This utmost thin skin, or Cuticle, may two manner of ways be made apparent by it self, and separated from the other, as by burning with fire, or ardent heat of the Sun, (in some delicate bodies, and such as are not accustomed to be conversant in Sunshine.) The quantity in thickness is very small, but the extent is most large, because it covers all the skin; the figure of it is round, and long, like those parts which it invests. The composition of it is obscure; yet because this Cuticle is the excrement of the true skin; we say it hath its matter from the excrementitious superfluity of the nerves, veins, arteries, and substance of the true skin.

The matter of the Cuticle.

The quantity.

The figure.
The composition.

The number.

The temperature.

It is in number one, like as the true skin which it outwardly covers, that it might be a *medium* between the object and fixed faculty of touching, diffused over all the true skin, which every where lies under it. For the temperature, by the common consent of Physicians, it is in the midst of all excess; for that seeing it is the *medium* between the object and faculty, if it should be hotter, colder, moister, or drier, it would deceive the faculty by exhibiting all objects, not as they are of themselves, but as it should be; no otherwise than as to such as look through red or green spectacles, all things appear red or green. Wherefore for this reason it was convenient the Cuticle should be void of all sense. It hath no action in the body; but it hath use, for it preserves and beautifies the true skin; for it seems to be given by the singular indulgence of nature, to be a muniment and ornament to the true skin. This providence of Nature, the industry of some Artizans (or rather Curtizans) doth imitate; who for to seem more beautifull, do smooth and polish it. By this you may understand, that not all the parts of the body have action, yet have they their use, because, according to *Aristotles* opinion, Nature hath made nothing in vain. Also you must note that this thin skin or Cuticle being lost, may every where be regenerated, unless in the place which is covered with a scar. For here the true skin being deficient, both the matter and former faculty of the Cuticle is wanting.

The use.

Why the Cuticle cannot be restored in scars.

C H A P. IIII.

Of the true Skin.

The true skin called by the Greeks *Derma*, is of a spermatick substance, wherefore being once lost, it cannot be restored as formerly it was. For in place thereof comes a scar, which is nothing else but flesh dried beyond measure. It is of sufficient thickness, as appears by the separating from the flesh.

The substance.
Magnitude.

But for the extent thereof, it encompasses the whole body, if you except the eyes, ears, nose, privities, fundament, mouth, the ends of the fingers where the nails grow, that is, all the parts by which any excrements are evacuated. The figure of it is like the Cuticle, round and long, with its productions, with which it covers the extremities of the parts.

Figure.

It is composed of nerves, veins, arteries, and of a proper flesh and substance of its kind, which we have said to be spermaticall, which ariseth from the process of the secundine, which lead the spermatick vessels even to the navell; in which place each of them into the parts appointed by nature, send forth such vessels as are spread abroad and diffused from the generation of the skin. Which also the similitude of them both, that is, the skin and

Composition.

- and membrane *Chorion* do argue. For as the *Chorion* is double, without sense, encompassing the whole infant, lightly fastened to the first coat, which is called *Amnios*; so the skin is double, and of it self insensible, (for otherwise the nerves were added in vain from the parts lying under it) ingirting the whole body, lightly cleaving to the fleshy Pannicle. But if any object, That the Cuticle is no part of the true skin, seeing it is wholly different from it, and easily to be separated from it, and wholly void of sense: I will answer, these arguments do not prevail. For that the true skin is more crasis, thick, sensible, vivid, and fleshy, is not of it self, being rather by the assistance and admixture of the parts, which derived from the three principall it receives into its proper substance; which happens not in the Cuticle. Neither if it should happen, would it be better for it, but verily exceeding ill for us, because so our life should lye fit and open to receive a thousand externall injuries, which encompass us on every side, as the violent and contrary access of the four first qualities.
- The number.**
Connexion. There is only one skin, as that which should cover but one body, the which it every where doth, except in those places I formerly mentioned. It hath connexion with the parts lying under it by the nerves, veins, and arteries, with those subjacent parts put forth into the skin investing them, that there may be a certain communion of all the parts of the body amongst themselves.
- Temperature.** It is cold and dry in its proper temper, in respect of its proper flesh and substance, for it is a spermaticall part. Yet if any consider the sinews, veins, arteries, and fleshy threds which are mixed in its body, it will seem temperate, and placed (as it were) in the midst of contrary qualities, as which hath grown up from the like portion of hot, cold, moist, and dry bodies. The use of the skin is to keep safe and sound the continuity of the whole body, and all the parts thereof, from the violent assault of all externall dangers; for which cause it is every where indued with sense, in some parts more exact, in others more dull, according to the dignity and necessity of the parts which it ingirts, that they might all be admonished of their safety and preservation. Lastly, it is penetrated with many pores, as breathing-places, as we may see by the flowing out of sweat, that so the arteries in their *diastole* might draw the encompassing air into the body, for the tempering and nourishing of the fixed inbred heat, and in the *lystole* expell the fuliginous excrement, which in Winter suppress by the cold air encompassing us, makes the skin black and rough. We have an argument and example of breathing through these, by drawing the air in by transpiration, in women troubled with the mother, who without respiration live only for some pretty space by transpiration.
- Ufe.**
- The reason why the skin is blacker and rougher in Winter.**

C H A P. V.

Of the fleshy Pannicle.

- What a membrane is.** fter the true skin, follows the membrane, which Anatomists call the fleshy Pannicle, whose nature that we may more easily prosecute and declare, we must first shew what a Membrane is, and how many ways the word is taken. Then wherefore it hath the name of the fleshy Pannicle. A membrane therefore is a simple part, broad and thin, yet strong and dense, white and nervous, and the which may easily without any great danger be extended and contracted. Sometimes it is called a coat, which is, when it covers and defends some part. This is called the fleshy Pannicle; because in some parts it degenerates into flesh, and becomes musculous, as in a man from the collar-bones, to the hair of the head, in which part it is therefore called the broad muscle, whereas in other places it is a simple membrane, here and there intangled with the fat lying under it, from whence it may seem to take or borrow the name of the fatty Pannicle. But in beasts (whence it took that name, because in those a fleshy substance maketh a great part of this Pannicle) it appears manifestly fleshy and musculous over all the body, as you may see in Horses and Oxen; that by that means being moveable, they may drive and shake off their flies, and other troublesome things, by their shaking and contracting their backs. These things considered, we say the fleshy Pannicle in its proper body, is of a nervous or membranous substance, as that which hath its originall from the coat *Amnios*, (which is next to the infant) dilated near to the navell, and stretched forth for the generation of this Pannicle; in which thing I think good to note, that as the membranes *Chorion* and *Amnios* mutually interwoven with small nervous fibers, encompass and invest the child as long as it is contained in the womb; so the skin and fleshy Pannicle, knit together by such like bands, engirt the whole body.
- Why it is sometimes called a coat, sometimes the fleshy and fatty Pannicle.**
- Why beasts have this Pannicle wholly fleshy or musculous.**
- The substance.** Therefore the fleshy Pannicle is equal in magnitude and like in figure to the true skin, but that it lyes under it, and is contained in it, in some places mixt with the fat, in others increased by the flesh interwoven with it, and in other some is only a simple membrane.
- The magnitude and figure.**
- Number.**
- Composure.** The composition of it is such, as the sight of it presents to our eye, that is, of veins, arte-

arteries, nerves, and the proper flesh, some whites mixed and interlaced with fat, and sometimes with musculous flesh. It is but one, by reason of the use we shall presently shew; it is situated between the skin and fat, or common coat of the muscles, annexed to these and the other parts lying under it, by the veins, nerves and arteries ascending from these inward parts, and implanting themselves into the substance thereof; and then into the true skin.

The temperature thereof is diverse, according to the variety of the parts interwoven with it. The use of it is, to lead, direct, and strengthen in their passage, the vessels which are disseminated into the true skin, and the whole superficies of the body. But in beasts it hath another commodity, that is, it gives a shaking or trembling motion to their skin and back, for that cause we formerly touched.

The temperature.
The use.

CHAP. VI.

Of the Fat.

The Fat coming near the condition of an excrement, rather than of a part (as we said, when we treated of the similar parts) is of an oily substance, bred of the aery and vaporous portion of the blood, which sweating through the pores of the coats, or mouths of the vessels, becomes concrete about the membranes, and nerves, and cold bodies, and turns into fat by the coldness of the place. Whereby we may know, that cold, or a more remits heat, is the efficient cause of fat, which is manifest by contemplation not only of creatures of divers kinds, but also by those of the same species and sex, if so be that the one be colder than the other.

By which we may understand that the fat is the more or less in quantity, according to the different temper of the whole body, and of its particular parts; for its composition, it consists of that portion of the blood which we formerly mentioned, intermixt with certain membranes, nervous fibers, veins and arteries. The greatest part of it lyes between the fleshy Pannicle, and the common coat of the Muscles. * Otherwise it is diffused over all the body, in some places more, in some less, yet it is always about the nervous bodies, to which it delights to cleave. Most Anatomists enquire whether the fat lye above or beneath the fleshy Pannicle. But we think this question is both impertinent and idle; being we often see the fat to be on both sides. *a* It is of a middle temper between heat and cold, being it ariseth of the more aery portion of the blood; although it may seem cold in respect of the efficient cause, that is, of cold by which it concretes. For the rest, moisture is predominant in the fat. *b* The use thereof is, to moisten the parts which may become dry by long fasting, vehement exercise, or immoderate heat; and besides to give heat, or keep the parts warm. Although it do this last rather by accident, than of its own nature, as heated by exercise, or by some such other chance; it heats the adjacent parts, or may therefore be thought to heat them, because it hinders the dissipation of the native and internall heat; like as cold heats in winter, whereby the bellies are at that time the hotter. I know some learned Physicians of our time stiffly maintained, that the fat was hot, neither did they acknowledg any other efficient cause thereof, than temperate heat and not cold. But I think it best to leave the more subtil agitation of these questions to naturall Philosophers. But we must note, *c* that at the joints which are more usually moved, there is another sort of Fat, far more solid and hard, than that which we formerly mentioned; often found mixed with a viscid and tough humor like the whites of Eggs, that so it might be sufficient for a longer time to moisten these parts, subject to be hurt by dryness, and make them slippery, and so fitter for motion, in imitation whereof they usually grease hard bodies, which must be in frequent motion, as Coach-wheels and axletrees. And there is another kind of fat, which is called *Sevum*, seam, in one thing differing from the ordinary fat, that is much dryer; the moister and softer portion of the fat being dissipated by the raging heat of the place. For it is found principally about the niddriff, where there are many windings of arteries and veins; and it is also about the reins, loins, and basis of the heart. The Fat is wasted by long fasting; is dryed and hardened by vehement exercise and immoderate heat. Hence it is that it is much more compact in the palms of the hands, and soles of the feet, about the eyes and heart, so that it resembles the flesh in density and hardness; because by the continuall motion and strong heat of these parts, the thinner portion being dissipated and diffused, the more gross and terrestriall remain.

The Fat is rather an excrement than a part. The substance.

The efficient causa of Fat.

The quantity.

The composition.

The fire.

I was present at the opening of a body. Feb. 1630. in which the fat in the lower part of the lower belly was in thickness above 8 inches, upon the breast between 4 and 5 inches: which I thought good to remember in this place both for the rarity of the thing, as also because it was increased by re ports, and the place mistaken some saying the *Omentum* or Call was so thick, which was false, for it did not much exceed the quantity of that part, in other fat men.

a The temper.
b The use.
c The solid fat, or seam.

In what parts, and for what cause the fat is more deafe.

C H A P. VII.

Of the common coat of the Muscles.

The substance.	<p>NExt under the Fat, appears a certain coat, spread over all the Muscles, and called the common coat of the Muscles, it is of a nervous substance, as all other membranes are. The quantity and breadth thereof is bounded by the quantity of the Muscles which it involves, and fits it self to, as that which encompasses the Muscles of the <i>Epigastrium</i>, is of equal largeness with the same Muscles. The figure of it is round: it is composed of veins, nerves, arteries, and its peculiar flesh consisting of three sorts of fibers; the beginning of it is from the <i>Periostium</i>, in that part where the bones give ligaments to the Muscles; or according to the opinion of others, of the nervous and ligamentous fibers of the Muscles, which rising up and diffused over the fleshy superficies thereof, are united for the generation of this coat. But this membrane arising from the <i>Periostium</i> (as every membrane which is below the head takes it originall from the <i>Periostium</i> either primarily, by the interposition of no Medium, or secondarily) is stretched over the Muscles by their tendons. But if any object, That this membrane pluck'd from the belly of the Muscle, may seem to end in a ligament. I will answer, that it is the condition of every nervous part, so to binde or fasten it self to another part of his own kinde as to a stay, so that it can scarce be pluck'd from thence. We see the proof hereof, in the <i>Peritonæum</i> or Rim in the <i>Epigastrium</i> or lower part of the lower belly. That which covers the Muscles of the <i>Epigastrium</i> is but one, unless you had rather part it in two, the right and the left distinguished by the interposition of the <i>Linea Alba</i>, or white Line. It is situate betwixt the Fat and Muscles; for it is fastened above and below to these parts with fibers, which in smalness and fitness exceed the Spiders web. But by its vessels, it participates with the three principall parts, and is of a cold and dry temper. The use of it is, to contain the Muscles in their naturall union, and to keep them as much as in it lyes, from putrefaction, which may happen to them from <i>pus</i> or matter, which is often cast forth of the similar parts into the empty spaces and distances of the Muscles. Wherefore going about to separate the Fat of the <i>Epigastrium</i> (where thou must begin the dissection of mans body) you must have a care that you hurt it not with your knife, but that, before you touch the Muscles, see you artificially take it away, that you may the more easily separate the Muscles lying under it, distinguished by a manifest space at the white Line, which is made by the meeting together of the proper coats of all those Muscles.</p>

What the white line is.	

C H A P. VIII.

What a Muscle is, and how many differences there be thereof.

What a Muscle is.	<p>AMuscle is the instrument of voluntary motion; and simple voluntary motion is performed six manner of ways, upwards, downwards, forwards, backwards, to the right hand and to the left; but the compound one way, which is circularly, the which is performed by the continuall succession of the motion of the Muscles ingirting the part. Such a motion Falconers use when they stretch forth their hand and lure their Hawk. We have some parts, which have motion without a Muscle, but that motion is not voluntary; such parts be the heart, stomach, guts, both the bladders, (that is, that of the gall and that of the urine) and divers other which have the motions of attraction, expulsion and retention, by the means of the three sorts of fibers; for they draw by the right, expell by the transverse, and retain by the oblique. The differences of Muscles which are many and diverse, are taken from their substance, originall, insertion into the part which they move, form or figure, holes or openings, magnitude, colour, site, kinde of fibers, their conjugation or connexion, heads, bellies, tendons, opposition in action and office. Some in substance are nervous, venous, arterious, because they have manifest nerves, veins, and arteries, as the Midriff, the Intercofall or Epigastrick Muscles, and many more, and that for their difference from other Muscles, into which neither nerve, nor vein, or arteries are manifestly inserted, although secretly they admit them all for sense and motion, life and nourishment; such are the Muscles of the wrist, the wormy Muscles of the hands and feet; for if there be any nerves observed in them, they are very small. Some had rather make the difference of Muscles thus, that some of them are fleshy, some nervous, others membranous. From their Originall, some arise from the bones, as these which move the hands, arms, and legs; others from gristles, as the Muscles of the throat; others from membranes which invest the tendons, as the wormy Muscles of the hands and feet; others from ligaments, as the Extenders of the fingers; others from other Muscles, as the two lower Muscles of the yard which proceed from the Sphincter Muscle of the fundament. Others have no originall, as the membrane which we call the fleshy Pannicle assumes flesh</p>
How the circular motion is performed.	
From whence the differences of Muscles are drawn.	
Differences of Muscles from their substance	
Differences of Muscles from their originall.	

in certain places, and degenerates into a Muscle; such are the *Cremaster* or hanging Muscles of the testicles, the large Muscles of the face, and if you please the Midriff, as that which is composed of two coats, the one encompassing the ribs and the *Peritonæum*, hath flesh in the midst between the two membranes. And moreover some Muscles have their originall from one only bone, as these which bend and extend the Cubit; others arise of many bones, as the oblique descending, the Dorsall and many Muscles of the neck, which arise together from many spondyls and sides of spondyls. There be others, according to the opinion of some men, both from the bones and gristles of the *Pubis* at the right or direct Muscles of the *Epigastrium*, yet by their favor I think otherwise. Because by the Anatomical and received axiome, A muscle is there thought to take his beginning, from whence he receives a nerve; but these Muscles take a nerve from the intercostall muscles, wherefore their originall ought to be referred to the sides of the breast-blades, as shall be shewed in due place. From their insertion arise these differences, some are inserted into a bone, as those which move the head, arms and legs; others into a gristle, as those of the Throtle; eye-lids, nose, and the oblique ascendent muscles of the *Epigastrium*; some into a bone and gristle both, as the right muscles of the *Epigastrium* and the Midriff; some into the skin, as the muscles of the lips; others into the Coats, as the muscles of the eyes; others into Ligaments, as the muscles of the yard. But these differences following may be drawn both from their insertion and originall. For some muscles arising from many parts, are inserted into some one part, as divers of these which move the arm and the shoulder, which arising from many spondyls, are inserted into the bone of the shoulder, and the shoulder-blade. Others arise from one part, and insert themselves into more, as those which arise from the bottom of the shoulder-blades, are extended and inserted into some eight or nine of the upper ribs, to help respiration; and the benders and extenders of the fingers and toes: Others arising from many bones, are inserted into as many, as some of those which serve for respiration, to wit those which we call the hinder Saw-muscles and the *Semispinatus*, which sends a tendon into all the ribs. Others have their originall from many bones, and end in gristles of the seven ribs, as those two which lye under the *Sternum*. Moreover also these differences of muscles may be drawn from the originall and insertion, that some proceed from bones, and are inserted into the next bone, to help and strengthen the motion thereof, as the three muscles of the Hip: Others arise from an upper bone and are not inserted into the next, but into some other, as the long muscles. Some are named from the part they move, as the temporall muscles, because they move the temples; others from their office, as the grinding muscles, because they move the skin as a mill, to grinde a funder the meal. From their form or figure, because some are like Mice, other like Lizards which have their legs cut off, for that they imitate in their belly, body or tendon, the belly or tail of such creatures, and from whence the names of *Musculus* and *Lacertus* are derived. Such are those which bend the wrist, and which are fastned to the bone of the Leg, and which extend the foot; others are triangular, as that which lifts up the arm, called *Epomis* or *Deltoides*, and that which draws the arm to the breast, called the Pectorall muscle. Others quadrangular, as the Rhomboides, or Lozenge-muscle of the shoulder-blade, and the two hindersom-muscles serving for respiration, and two of the wrists which turn down the hand; others consist of more than four angles, as the oblique descending, and that muscle which joins it self to it from the shoulder-blade; others are round and broad, as the Midriff; others circular, as the Sphincter-muscle of the fundament and bladder; others are of a pyramidicall figure, as the seventh muscle of the ey, which compasses the optick nerve in beasts but not in men. Others have a semicircular form, as that which shuts up the ey, seated at the lesser corner thereof; others resemble a Monks cowl, or hood, as the *Trapezius* of the shoulder-blade. Besides others at their first originall are narrow, but broad at their insertion, as the Saw-muscle of the shoulder, and the transverse of the *Epigastrium*; others are quite contrary, as the three muscles of the Hip; others keep an equal breadth or bigness in all places, as the intercostall muscles and these of the wrist; others are long and slender, as the long muscle of the thigh; others are long and broad, as the oblique descending muscles of the *Epigastrium*; others are directly contrary, as the Intercostall, which are very narrow. From their perforations, for some are perforated, as the Midriff which hath three holes, as also the oblique and transverse of the *Epigastrium*, that so they may give passage forth to the preparing spermatick vessels, and to the ejaculatory vessels, the Coat *Erythroides* associating and strengthening them; others are not perforated. From their magnitude, for some are most large, as the two muscles of the Hip; others very small, as the eight small muscles of the neck, and the proper muscles of the Throtle, and the wormy muscles. Others are of an indifferent magnitude. From their colour, for some are white and red, as the Temporall muscles, which have tendons coming from the midst of their belly; others are livid, as the three greater muscles of the calf of the leg, which colour they have by the admixtion of the white, or tendinous nerve coat with the red flesh, for this coat by its thickness darkning the colour of the flesh, so that it cannot shew its redness and fresh colour, makes it seem of that livid colour. From their situation, for some are superficially, as those which appear under the skin and fat; others deep in and hid, as the smooth and four twin muscles; some are stretched

Where a Muscle hath its originall.

Differences of muscles from their insertion;

Differences of Muscles taken from their figure.

Differences from their perforations;

From their magnitude.

From their colour.

From their site.

stretched out, and (as it were) spread over in a straight and plain passage, as the muscles of the thigh which move the leg, except the Ham-muscle; others oblique, as those of the *Epigastrium*; othersome transverse, as the transverse of the *Epigastrium*; where you must observe, that although all the fibers of the muscles are direct, yet we call them oblique and transverse, by comparing them to the right muscles, as which by the concurrence of the fibers make a straight or acute angle.

From their
Fibers.

From the sorts of fibers; for some have one kinde of fiber; yet the greatest part enjoy two sorts running so up and down, that they either are crossed like the letter X, as happens in the pectorall and grinding muscles; or else do not concur, as in the Trapezii. Others have three sorts of fibers, as the broad muscle of the face.

From their
connexion.

From their coherence and connexion, or their texture of nervous fibers; for some have fibers somewhat more distant and remote immediately at their original, than in other places, as you may see in the muscles of the buttocks: Others in their midst and belly, which by reason thereof in such muscles is more big or tumid, their head and tail being slender, as happens in most of the muscles of the arm and leg, in which the dense mats of flesh interwoven with fibers, disjoins the fibers in so great a distance; in othersome the fibers are more distant in the tail, as in the greater Saw-muscle arising from the bottom of the shoulder-blade; in others they are equally distant through the whole muscle, as in the muscles of the wrist and between the ribs.

From their
head.

From their head; for in some it is fleshy, interwoven with few fibers, as in the muscles of the buttocks; in others it is wholly nervous, as in the most-broad-muscle common to the arm and shoulder-blade, and in the three muscles of the thigh proceeding from the tuberosity of the huckle-bone; in some it is nervous and fleshy, as in the internall and externall muscle of the arm. Besides, some have one head, others two, as the bender of the elbow, and the externall of the leg; others three, as the Threeheaded muscle of the thigh. But we must note that the word Nerve or Sinew is here taken in a large signification, for a ligament, nerve and tendon, as *Galen* saith, (*Lib. de Ossibus*) and moreover we must observe, that the head of a muscle is one while above, another while below, otherwhiles in the midst, as in the Midriff, as you may know by the insertion of the Nerve, because it enters the muscle by its head.

From their
belly.

From their belly also, there be some differences of muscles taken; for some have their belly immediately at their beginning, as the muscles of the buttocks; others at their insertion, as the Midriff; others just at their head, as those which put forth the Calf of the leg; in others it is somewhat further off, as in those which draw back the arm, and which bend the leg; in others, the belly extends even from the head to the tail, as in the intercostall muscles, and these of the wrist; in others it is produced even to their insertion, as in those of the palms of the hands and soles of the feet; some have a double belly distinguished by a nervous substance; as those which open the mouth, and those which arise from the root of the lower process of the shoulder-blade.

From their
Tendons.

Moreover the differences of muscles are drawn also from the Tendons, for some have none, at least which are manifest, as the muscles of the lips and the sphincter-muscles, the intercostall and those of the wrist; others have them in part, and want them in part, as the Midriff; for the Midriff wants a Tendon at the ends of the shorter ribs, but hath two at the first *Vertebra* of the Loins in which it is terminated: Others have a Tendon indeed. But some of these move with the bone, some not, as the muscles of the eyes; and besides, some of these have broad and membranous tendons, as the muscles of the eyes and *Epigastrium*, except the right muscles: In others they are thick and round, as in the benders of the fingers; in others they are less round, but more broad than thick, such is the Tendon arising from the twin muscles and *Soleus* of the leg; others have short Tendons, as the muscles which turn down the hand; othersome long, as those of the palms of the hands, and soles of the feet; besides others produce Tendons from the end of their belly, which Tendons are manifest; others from the midst, as the Temporall muscles.

From their
action.

From their
function.

Besides also, others diffuse many Tendons from their belly, as in the hands the benders of the fingers, and the extenders of the feet. Othersome put forth but one, which sometimes is divided into many, as those which bend the third articulation of the foot; otherwhile many muscles by their meeting together make one Tendon, as the three muscles of the Calf of the leg, and those which bend the cubit and leg. All Tendons have their original, when the nerves and ligaments dispersed through the fleshy substance of a muscle, are by little and little drawn and meet together, untill at last carried to the joint, they are there fastned for the fit bending and extension thereof. From the contrariety of their Actions, for some parts have contrary muscles, benders and extenders; other parts have none, for the Cods and fundament have only lifters up. From their function, for some are made for direct motions, as those which extend the fingers and toes; others for oblique, as the Supinators of the hand, and the Pronators; others perform both, as the pectorall muscle, which moves the Arm obliquely upward and downward, as the upper and lower fibers are contracted; and also outright, if all the fibers be contracted together, which also happens to the *Deltoides* and *Trapezius*. I have thought it good to handle particularly

larly these differences of muscles, because that by understanding them the prognostick will be more certain; and also the application of remedies to each part; and if any occasion be either to make incision, or suture, we may be more certain whether the part affected be more or less nervous.

CHAP. I X.

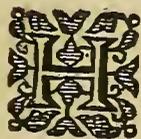

Of the parts of a Muscle.

Having declared the nature and differences of a Muscle, we must note that some of the parts thereof are compound or universall, others simple or particular. The compound are the head, belly, and tail. The simple are ligaments, a nerve, flesh, a vein, artery and coat. For the compound parts, by the head, we understand the beginning and originall of a muscle, which is one while ligamentous and nervous, otherwhiles also fleshy. By the belly, that portion which is absolutely fleshy; But by the tail we understand a Tendon consisting partly of a nerve, partly of a ligament promiscuously coming forth from the belly of the muscle. For as much as belongs to the simple, which are six in number, three are called proper, and three common. The proper are a Ligament from a bone, a nerve proceeding from the Brain or spinall marrow, and flesh compact by the concretion of blood. The common are, a vein from the Liver or trunk arising from thence; an artery proceeding from the Heart, a Coat produced by the nervous and ligamentous fibers spreading over the superficies of the muscle. But for the simple use of all such parts, the nerve is (as it were) the principall part of a Muscle, which gives it sense and motion, the ligament gives strength, the flesh contains the nervous and ligamentous fibers of the Muscle, and strengthens it, filling up all the void spaces, and also it preserves the native humidity of these parts, and cherisheth the heat implanted in them; and to conclude, defends it from all externall injuries; for like a fan it opposeth it self against the heat of the Sun; and is as a garment against the cold; and is as a cushion in all falls and bruises; and as a buckler or defence against wounding weapons. The vein nourishes the muscle, the artery gives it life, the coat preserves the harmony of all the parts thereof, lest they should be any ways disjointed or corrupted by purulent abscesses breaking into the empty or void spaces of the Muscles, as we see it hapneth in a Gangrene, where the corruption hath invaded this membrane, by the breathing out of the more acrid matter or filth.

The compound and simple parts of a muscle.

What use each simple particle hath in a muscle.

CHAP. X.

A more particular inquisition into each part of a muscle.

Having gone thus far, it remains, that we more particularly inquire into each part of a muscle, that (if it be possible) nothing may be wanting to this discourse. Wherefore a Ligament properly so called, is a simple part of mans body, next of a bone and gristle, the most terrestriall, dry, hard, cold, white, taking its originall immediately, or by the interposition of some Medium from the Bones or Gristles (from whence also the Muscles have their beginning) whereby it comes to pass, that a ligament is void of sense, unless it receive a nerve from some other place; (for so the ligaments which compose and strengthen the tongue and yard, are partakers of sense, and it inserts it self into the bone and gristle, that so it may bind them together, and strengthen and beautifie the whole joint or connexion; (for these three be the principall uses of a ligament) then diffusing it self into the membranes and muscles to strengthen those parts. A Nerve, to speak properly, is also a simple part of our body, bred and nourished by a gross and phlegmatick humor, such as the brain, the originall of all the nerves, and also the Spinall marrow endued with the faculty of feeling, and oftentimes also of moving. For there be divers parts of the body which have nerves, yet are destitute of all voluntary motion, having the sense only of feeling, as the membranes, veins, arteries, guts, and all the entrails. A nerve is covered with a double cover from the two membranes of the brain, and besides also with a third proceeding from the ligaments which fasten the hinder part of the head to the *Vertebra's*, or else from the *Pericranium*. We understand no other things by the fibers of a Nerve, or of a Ligament, than long and slender threds, white, solid, cold, strong, more or less, according to the quantity of the substance, which is partly nervous and sensible, partly ligamentous and insensible. You must imagine the same of the fleshy fibers in their kinde; but of these threds some are streight for attraction; others oblique, for retention of that which is convenient for the creature; and lastly, some transverse, for expulsion of that which is unprofitable. But when these transverse threds are extended in length, they are lessened in bredth; but when they are directly contracted, they are shortned in length. But when they are extended all together as it were with an unanimous consent, the whole member

sorts the flesh
is.

is wrinkled as contracted into it self, as on the contrary it is extended when they are relaxed. Some of these are bestowed upon the animall parts, to perform voluntary motions; others upon the vitall to perform the agitation of the heart and arteries; others upon the naturall for attraction, retention, and expulsion. Yet we must observe, that the attraction of no similar part is performed by the help of the foresaid fibers or threds, but rather by the heat implanted in them, or by the shunning of emptiness, or the familiarity of the substance. The flesh also is a simple and soft part, composed of the purer portion of the blood insinuating it self into the spaces between the fibers, so to invest them for the uses formerly mentioned. This is (as it were) a certain wall and bulwark against the injuries of heat and cold, against all falls and bruises, as it were a certain soft pillow or cushion yielding to any violent impression. There be three sorts of flesh; one more ruddy, as the muscularous flesh of perfect creatures, and such as have blood; for the flesh of all tender and young things having blood, as Calves, and also of all sorts of fish, is whitish, by reason of the too much humidity of the blood. The second kinde is more pallid, even in perfect creatures having blood, such is the flesh of the heart, stomach, weasond, guts, bladder, womb. The third is belonging to the entrails, or the proper substance of each entrail, as that which remains of the Liver (the veins, arteries and coat being taken away) of the bladder of the gall, brain, kidneys, milt: Some add a fourth sort of flesh which is spongy, and that they say is proper to the tongue alone.

What a vein is.

A Vein is the vessel, pipe, or channel of the blood, or bloody matter; it hath a spermatick substance, consists of one coat composed of 3 sorts of fibers.

What an artery is.

An Artery is also the receptacle of blood, but that spirituou and yellowish, consisting in like manner of a spermatick substance; But it hath two coats with three sorts of fibers, the utmost whereof is most thin, consisting of right fibers, and some oblique: But the inner is five times more thick and dense than the utmost, interwoven with transverse fibers; and it doth not only contain blood and spirit, but also a serous humor, which we may believe because there be two emulgent Arteries as well as veins.

Why an artery
is more thick
and dense than
a vein.

But the inner coat of an Artery is therefore more thick, because it may contain blood which is more hot, subtil, and spirituou; for the spirit, seeing it is naturally more thin and light, and in perpetuall motion, would quickly fly away, unless it were held in a stronger hold. There is other reason for a Vein, as that which contains blood gross, ponderous, and slow of motion. Wherefore if it had acquired a dense and gross coat, it could scarce be distributed to the neighbouring parts: God the maker of the Universe, foreseeing this, made the coats of the vessels contrary to the consistence of the bodies contained in them. The *Anastomosis* of the Veins and Arteries, that is to say, the application of the mouths of the one to the other, is very remarkable, by benefit of which they mutually communicate and draw the matters contained in them, and so also transfuse them by insensible passages, although that *anastomosis* is apparent in the Vein and Artery that meet together at the joint and bending of the arm, which I have sometimes shewed in the Physick schools, at such time as I there dissected Anatomies.

The mutuall
Anastomosis of
the veins and
arteries.
Where it is
manifest.

From whence
a muscle hath
its beginning
or head.

But the action or function of a Muscle is either to move or confirm the part according to our will, into which it is implanted; which it doth when it draws it self towards its originall, that is to say, its head. But we define the head by the insertion of the nerve, which we understand by the manner of the working of the Muscle.

CHAP. XI.

Of the muscles of the Epigastrium, or lower Belly.

Now seeing that we have taught what a Muscle is, and what the differences thereof are, and what simple and compound parts it hath, and what the use, action, and manner of action in each part is; it remains that we come to the particular explication of each Muscle, beginning with those of the lower belly, as those which we first meet withall in dissection.

Eight muscles
of the Epiga-
strium.

These are 8 in number, four oblique, two on each side, two right or direct, one on the right, another on the left side; and in like manner two transverse. All these are alike in force, magnitude and action, so mutually composed, that the oblique descendant of one side, is conjoined with the other oblique descendant on the other side, and so of the rest.

The oblique
descendant.
Their sub-
stance.
Their greatnes
and figure.

We may add to this number the two little Supplying or Assisting muscles, which are of a *Pyramidall* form, and arise from the Share-bone, above the insertion of the right muscles; Of the oblique Muscles of each side the one ascends, the other descends, whereupon it comes to pass, that they are called the Oblique descendant and ascendant Muscles. Those oblique which we first meet with, are the descendant, whose substance is partly sanguine, partly spermatick; for they are fleshy, nervous, ligamentous, veinous, arterious, and membranous. Yet the fleshy portion is predominant in them, out of which respect *Hippocrates* is wont to express the muscles by the name of fleshes; their greatnes is indifferent be-

between the large and the small muscles; their figure is three square. They are composed of the forementioned parts, they are two in number; their site is oblique, taking their beginning from the touching of the great saw-muscle, and from the sixth and seventh true ribs, or rather from the spaces between the six lower ribs, and rather on the forepart of the muscles, than of the ribs themselves, from whence shunning the *Vertebra's* of the Loins, the fleshy parts of them are terminated in the externall and upper eminency of the Haunch-bone, and the membranous end in the lower eminency of the Share-bone and the White-line. Yet *Columbus* dissenting from this common description of the oblique Muscles, thinks that they are only terminated in the White-line, and not in the Share-bone. For (saith he) wherefore should they be inserted into the Share-bone which is not moved? But because it would be an infinit labor and trouble to set down at large the severall opinions of all Authors of Anatomy; I have thought it sufficient for me to touch them lightly by the way. Their connexion is with the oblique ascendant lying under them, and with the direct or right. Their temperament is twofold, the one hot and moist, by reason of the belly and the fleshy portion of them; the other cold and dry, in respect of their ligamentous and tendinous portion. Their action is to draw the parts into which they are inserted towards their originall, or else to unite them firmly. Yet each of these privately and properly draws the hip in an oblique manner towards the *Cartilago Scutiformis* or breast-blade. Then follow the oblique ascendant, who have the same substance, quantity, figure, composition, number and temper the descendant have. They are situate between the descendant and transverse with whom they have connexion, especially by the vessels which are brought from the parts beneath. All the fleshy parts arise from the rackbones of the Haunch to the ends of the bastard ribs, which they seem to admit above and below, being fleshy even to the fourth, and then becoming membranous, they take their way to the White-line, with a double *aponeurosis*, which passes through the right Muscles above and below, as we may plainly see from the navell downwards. In their fleshy part they draw their original from the spine of the Haunch-bones a little lower than the descendent end in their fleshy part. But for their membranous parts, they arise before from the sharebone, but behinde from the spondyls of the Holy-bone, and *Vertebra's* of the Loins obliquely ascending upwards to the White-line, into which they are terminated by an *aponeurosis* or membranous tendon (which seems to penetrate the right Muscle upwards and downwards, especially under the navell) but by their fleshy part at the ends of all the bastard ribs, which they seem to receive above and below. And because these muscles are terminated in the White-line, they have also another use, yet such as is common to all the muscles of the *Epigastrum*, that is, to press down the Guts. Their action is (if they perform it together) to draw down the chest, and dilate the breast; but if their actions be separate, they draw the chest to the hip with an oblique motion. After these follow the right muscles, so called because they descend according to the length of the body, and because they have right or straight fibers.

We will say nothing (to shun prolixity, which in all other places we will avoid) of their substance and other conditions, which they have common with the fore-mentioned Muscles. They are situate in the eminentest or extuberating region of the belly, bounding the *Epigastrum* taken in generall, (or the superficial belly) they are divided by the manifest intercourse of the White-line, even to the Navell, in which place they seem to be united even to the place of their insertion. They draw their originall not from the Share-bone, as some would have it, but according to the insertion of their nerves from the sides of the *Cartilago scutiformis*, and the ends of the sixth, seventh and eighth ribs; but they end in the Share-bone, where they make a common Tendon sufficiently strong and short. *Sylvius*, *Vesalius*, and *Columbus* think they arise from the Share-bone, because they cannot be inserted into that bone, because it is unmovable. You may perceive in these Muscles certain nervous and transverse interfections, oftentimes three in number for the strength of these Muscles, (of which *Galen* makes no mention, although they may be seen in Apes.) And also in the inner side of these muscles you may see four veins, and as many arteries, of which some creep upwards, others run downwards. The upper, called the Mamillary, descend from the Axillary by the side and lower parts of the *Sternum*, the slenderer portions thereof being distributed by the way to the *Mediastinum*, and about the fourth and fifth rib to the Dugs, from whence they take their name.

That which remains breaking out by the sides of the Breast-blade, inserts it self into those muscles, creeping along, even almost to the navell; in which place they are manifestly united (that is, the veins with the veins, and arteries with the arteries) with the Epigastrick, which ascend from the upper part of the Iliacks on each side under the said muscles, untill they meet with these four mamillary vessels. That you may finde this concourse of the veins and arteries about the navell, you must follow both the upper and the lower somewhat deep into the flesh, pressing the blood on both sides from above downwards, and from below upward, untill you shall finde the exosculation of these vessels, which will appear by this, That the blood will flow from this into that, and from that into this; otherwise you can scarce perceive it, by reason of the smalness of such vessels which want blood.

Originall.

The meeting together of the Epigastrick and mamillary veins and arteries.

But that by the benefit of such concurrence of the vessels, the matters may be communicated and transported both from the womb to the dugs, and again from the dugs to the womb, appears in Nurses who want their courses, when the milk comes into their dugs; and on the contrary lose their milk when their courses flow plentifully. Otherwise to what purpose should there be such concurrence between the vessels of the paps and womb? for there are veins and arteries diffused to the sides of the womb from the root of the Epigastricks; for indeed the Epigastricks which in their ascent meet with the mamillary, go not to the womb, though they be next to them, and arise from the same trunk with the Hypogastrick vein of the womb. The action of these Muscles is, to move or draw near together the parts of the Hypogastrium to the *precordia* or Hypochondries. Their use, in *Columbus* opinion, is, to draw the breast downwards so to dilate it. At the ends of these, nature hath produced two other small Muscles from the upper part of the Share-bone, of a triangular figure, for the safety of the thick and common tendon of the right Muscles; whereupon they are called *Succenturiati*, or assisters. The first figure of the Lower belly.

Their action.

Their use.

The Pyramidal or assisting Muscles.

The transverse muscles of the *Epigastrium*. Their figure and sitc.

Their action. The common use and action of the eight muscles of the *Epigastrium*.

Some (moved with I know not what reason) would have these two small Muscles to help the erection of the yard. *Columbus* thinks they should not be separated from the right, and that they only are the fleshy beginnings of the right. But on the contrary, *Fallopis* manifestly proves them different and separate from the right, and shews their use. The Transverse remain to be spoken of, so called by reason of their fibers, which make right angles with the fibers of the right Muscles. They have a quadrangular figure situate upon the greatest part of the *Peritonæum*, to which they stick so close that they scarce can be separated. They take their originall from the production of the loins, the eminency of the Haunch-bone, the transverse productions of the *vertebra's* of the loins, and the ends of the bastard-ribs; contrary to the opinion of many, whom the insertion of the nerve convinces, but they end in the White-line, as all the rest do.

Their action is to press the guts, especially for the expulsion of excrements.

But all the eight recited Muscles, besides their proper use, have another common, that is, they stand for a defence or bulwark for all the parts lying under them, and serve for the expulsion both of the excrements, infant, and vapors, and also for the strengthening of

of the voice, as experience shews in those who sound Trumpets and Cornets.

Therefore these muscles do equally on every side press the Belly; but the Midriff, the intercostall muscles assisting it, doth drive from above downwards, from which conspiring contention follows the excretion of the excrements by the fundament; but unless the Midriff should assist, these muscles would press the excrements no more downwards, than upward to the mouth.

Although to this excretion of the excrements, it is not sufficient that the Epigastrick, Midriff, and intercostall muscles press the belly, but the muscles of the throat must be also shut. For the mouth being open, the excrements never go well forth; because the vapors that pass out of the mouth, which being restrained and driven to the Midriff, by stretching it powerfully thrusts down the excrement. Wherefore Apothecaries when they give glysters, bid the Patient to open his mouth, that the glyster may easly go up, which otherwise would scarcely go up, the mouth being shut, because so we should have no place empty in us, into which the glyster might be admitted.

Of the White-line, and Peritonæum or Rim of the belly.

The White-line is nothing else, than the bound and extremities of the muscles of the *Epigastrium*, distinguishing the belly in the midst into two parts, the right and left. It is called white, both of its own colour, and also for that no fleshy part lyes under it, or is placed above it. It is broader above the navell, but narrower below, because the right muscles do there grow into one. Now we must treat of the Coat or membrane, *Peritonæum* or *Rim* of the belly; it is so called, because it is stretched over all the lower belly; and particularly over all the parts contained in the ventricle, to which also it freely lends a common coat. It hath a spermatick substance, as all other membranes have; the quantity of it in thickness is very small, (for it is almost as thin as a Spiders web) yet differing in divers places in men and women; for men have it more thick and strong above the navell, that so it may contain the extension of the stomach, often stretched beyond measure with meat and drink. On the contrary women have it so thick and strong below their navell, that it seems double, that so they may more easily endure the distention of their womb, caused by the childe contained in it. But above the navell, men and women have the *Peritonæum* of an equal strength, for the self-same reason. The longitude and latitude of it is known by the circumscription of the belly.

The figure is round and somewhat long; it puts forth some productions, like finger-stalls, both for the leading and strengthening the spermatick vessels, and the Cremaster muscles of the Testicles, and besides it the ejaculatory vessels, as also to impart a coat to the Testicles and all the naturall parts.

It is composed of slender, membranous and nervous fibers, certain small branches of veins and arteries concurring with them, which it receives for life and nourishment from the adherent parts.

This membrane is one in number, and besides every where one and equal, although *Galen* would have it perforated in that place where the spermatick vessels descend to the Testicles; But in truth we must not think that a hole, but rather a production, as we said before,

The later Anatomists have observed, the Coat *Peritonæum* is doubled below the Navel, and that by the spaces of these reduplications the umbilicall arteries ascend to the Navell.

It is situate near the naturall parts, and compasses them about, and joined by the coat, which it gives them, as also on the sides, it is joined to the *vertebra's* of the loins, from whose ligaments (or rather *Periosteum*) it takes the originall: On the lower part, it cleaves to the share-bone, and on the upper to the Midriff, whose lower part it wholly invests; on the fore or outer part it sticks so close to the transverse muscles, that it cannot be plucked from them but by force, by reason of the complication and adhesion of the fibers thereof with the fibers of the proper membrane of these muscles, which membrane in *Galen's* opinion proceeds from this *Peritonæum*, that so it is no marvail that we may more easily break than separate these two coats. It is of temperature cold and dry, as all other membranes are.

It hath many uses; the first whereof is, to invest and cover all the parts of the lower belly, specially the Kall, lest it should be squeezed by great compressures and violent attempts into the empty spaces of the muscles, as it sometimes happens in the wounds of the *Epigastrium*, unless the lips of the ulcer be very well united; for then appears a tumor about the wound by the Guts and Kall thrusting without the *Peritonæum* into those spaces of the muscles; from whence proceeds cruel pain.

Another use is to further the casting forth of the excrements by pressing the ventricle and guts on the fore side, as the Midriff doth above, as one should do it by both their hands joined together.

The third use is, it prohibits the repletion of the parts with flatulency after the expulsion of the excrements, by straitning and pressing them down.

The fourth and last is, that it contains all the parts in their seat, and binds them to the back-bone, principally that they should not fly out of their places by violent motions, as leaping and falling from on high.

Why when the mouth is open the excrements go more slowly forth.

A cause of
frustrating
conception.

After the containing parts, follow the contained, the first of which is the *Epiploon*, (or *Kall*) so called, because it (as it were) swims upon all the guts. The substance of it is fatty and spermatick; the quantity of it for thickness is diverse, in divers men according to their temperament. The latitude of it is described by the quantity of the guts. It is in figure like a purse, because it is double. It is composed of veins, arteries, fat and a membrane, which sliding down from the gibbous part of the ventricle, and the flat part of the gut *Duodenum* and spleen over the Guts, is turned back from the lower belly to the top of the Colon. It is one as we said covering the Guts. It hath its chief connexion with the first *Vertebra's* of the Loins, from which place in beasts it seems to take a coat, as in men from the hollow part of the Spleen, and gibbous of the ventricle, and depressed part of the *Duodenum*, from whence doubled it is terminated in the fore and higher part of the Colick-gut. Which moved *Galen* to write, that the upper part of the membrane of the *Kall* was annexed to the ventricle; but the lower, to the laxer part of the Colick-gut. From the vessels of which parts it borrows his, as also the nerves, if it have any. The temper of it in lean bodies is cold and dry, because their *Kall* is without fat; but in fat bodies it is cold and moist by reason of the fat. The use of it is two-fold: The first is to heat and moisten the Guts, and help their concoction, although it do it by accident, as that which through the density of the fat hinders the cold air from piercing in, and also forbids the dissipation of the internall heat. Another use is, that in want of nourishment in times of great famine, for sometimes it cherishes, and (as it were) by its dew preserves the innate heat, both of the ventricle and neighbouring parts, as it is written by *Galen*. Moreover we must observe, that in a rupture or relaxation of the *Peritoneum*, the *Kall* falls down into the *scrotum*, from whence comes that rupture we call *Epiplocele*. But in women that are somewhat more fat, it thrusts it self between the bladder and the heck of the womb, and by its compression hinders; that the seed comes not with full force into the womb, and so frustrates the conception. Besides, when by a wound or some other chance, any part of it be defective, then that part of the belly which answers to it, will afterwards remain cold and raw, by reason of the forementioned causes.

C H A P. XIII.

Of the Ventricle or Stomach.

NOW we must speak of the Stomach, the receptacle of the food necessary for the whole body, the seat of appetite, by reason of the Nerves dispersed into its upper orifice, and so into its whole substance. The substance thereof is rather spermatick than sanguine, because that for one fleshy membrane, it hath two nervous; The quantity or magnitude of the ventricle is divers, according to the various magnitude of bodies, and gluttony of men. The figure of it is round and somewhat long, like a Bagpipe. The stomach is composed of two proper coats, and one common from the *Peritoneum*, together with veins, sinews, and arteries; the innermost of its proper coats is membranous woven with right fibers, for the attraction of meats, it is extended and propagated even to the mouth thereof, whereby it comes to pass that the affections of one part may easily be communicated to the other by sympathy, or consent. This coat hath its original from the membranes of the brain which accompany the nerves descending from the third and fourth conjugation to the mouth thereof. And in like sort from other productions descending by the passages of the head, from whence also another reason may be drawn from that, which they commonly bring from the nerves of the sixth conjugation; why in wounds of the head, the stomach doth so soon suffer by consent with the brain. The exterior or outer is more fleshy and thick, woven with oblique fibers, to retain and expell. It draws its original from the *Pericranium*, which as soon as it comes to the gullet, takes unto it certain fleshy fibers. There be nerves sent into the stomach from the sixth conjugation of the brain, as it shall be shewed in its proper place. Veins and arteries are spread into it from the *Gastrica*, the *Gastrepiploides*, the *Coronaria* and splenick, from the second, third, and fourth distribution of the *Vena porta*, or gate-vein; and the third of the descendent artery to the naturall parts, as soon as it passes forth of the midriffe.

It is one in number. The greater part of it is situated on the left side between the spleen, the hollownes of the liver, and the guts, that assisted by the heat of such neighbouring parts, it may more cheerfully perform the concoction of the meat. Neither am I ignorant that *Galen* hath written, that a great part of the stomach lies on the left side. But inspection it self, and reason makes me derogate from *Galens* authority, for because there is more empty space on the left side, by reason the spleen is less than the liver, it was fit it should lie more on the left side. The more proper connexion of it is with the gullet and guts, by its two orifices; with the brain by its nerves; with the liver and spleen by its veins; with the heart by its arteries; and with all the naturall parts by its common membrane.

The temper of the ventricle in men of good habit, is temperate, because it is almost composed of the equall mixture of sanguine and spermatick parts; or according to *Galens* opinion, it is cold of its self, and by the parts composing it; and hot by the vicinity of the bowels. But in some it is hotter, in others colder, according to the divers temper and complexion of divers bodies. That stomach is to be thought well tempered, that powerfully draws down the meat and drink, and embraces and retains them so drawn, untill by concoction and elixation, they shall be turned into a juice like cream (which the Greeks call *Chylos*;) and lastly, which doth strongly send from it, and repell the excrements of this first concoction.

The stomach is known to be hotter by this, that it better concocts and digests coarse and hard meats, as beef, hard eggs, and the like, than soft meats easie of digestion, which it corrupts and turns into belchings. For so a young chickin, is sooner burnt than well roasted at a great fire. The stomach which is colder, desires much meat, but is slow in concocting them, especially if they be cold and hard of digestion; which for that cause quickly turn sowre. The action of a well conditioned stomach is twofold, one common, another proper. The common is to attenuate, mixe and digest the meats taken in at the mouth, for the nutrition of it self and the whole body, after the liver hath performed its duty, which before it be done, the ventricle only enjoys the sweet pleasure of the *Chylus*; and comforts its self against the impurity of the adjacent parts, whereof it is called the work-house of concoction. Its first action is to attract, retain, and assimilate to it self that which is convenient; but to expell whatsoever shall be contrary, either in quantity, or quality, or in the whole substance.

It hath two orifices, one above, which they commonly call the stomach and heart, the other lower, which is called the *Pylorus*, or lower mouth of the stomach. The upper bends to the left side near the back bone; it is far more large and capacious than the lower, that so it may more commodiously receive meats half chewed, hard and gross, which Gluttons cast down with great greedines; it hath an exquisite sense of feeling, because it is the seat of the appetite, by reason of the nerves incompassing this orifice, with their mutuall imbracings; whereby it happens that the ventricle in that part is endued with a quick sense, that perceiving the want and emptines of meat, it may stir up the creature to seek food. For albeit

nature hath bestowed four faculties on other parts, yet they are not sensible of their wants, but are only nourished by the continuall sucking of the veins, as plants by juice drawn from the earth.

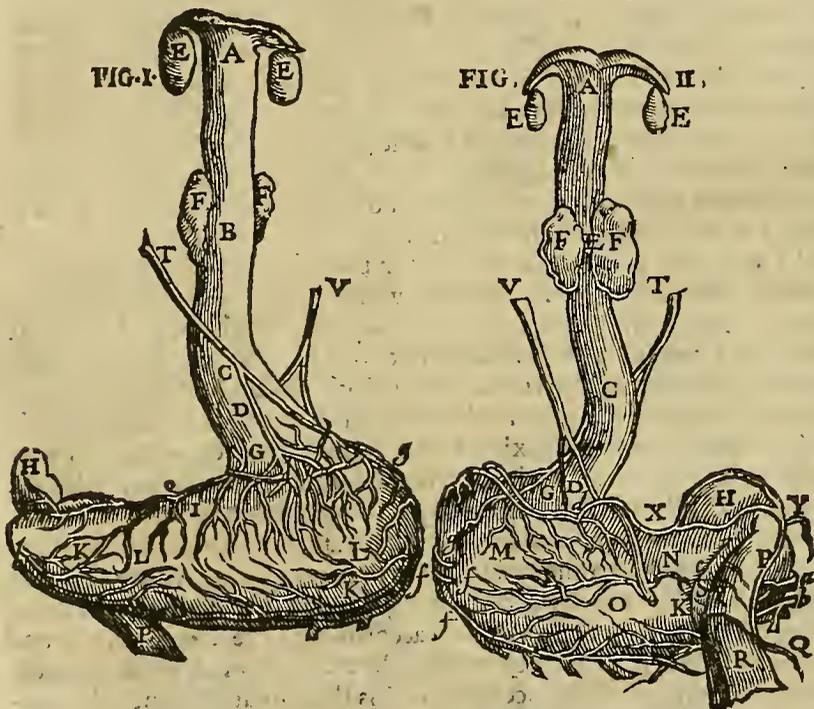

The site.

The glandulous ring of the *Pylorus*.

The falling down of the stomach.

This orifice is seated at the fifth *Vertebra* of the chest, upon which they say it almost rests. Yet I had rather say that it lies upon the twelfth *Vertebra* of the chest, and the first of the loins; for in this place the gullet perforates the midriff, and makes this upper orifice: The lower orifice bends rather to the right side of the body, under the cavity of the liver. It is far straiter than the upper, lest any thing should pass away before it be well attenuated and concocted; and it doth that by the help or assistance of, as it were, a certain ring, like to the sphincter muscle of the fundament, which some have thought a glandule made by the transposition of the inner and fleshy membrane of the ventricle into that, which is the outer of the guts. I know *Columbus* laughs at this glandulous ring, but any one that looks more attentively shall perceive that the *Pylorus* is glandulous. The stomach in its lower and inner side, hath many folds and wrinkles, which serve to hold and contain the meats, untill they be perfectly concocted. In the ventricle we observe parts gibbous and hollow; the hollow is next to the liver and midriff; the gibbous is towards the guts. Now we must note, that the ventricle when it is much resolved or loosed, may slide down even to the navill near the bladder, the which we have observed in some bodies dissected after their death.

The third and fourth figure.

The first figure shews the fore-side of the stomach and gullet.

- A. sheweth the orifice of the gullet cut from the throat.
- B. the straight and direct course of the gullet from A. to B.
- C. how the gullet above the first rack bone of the chest; from B. to C. inclineth to the right hand.
- D. his inclination to the left hand, from C. to D.
- EE. the two glandules called the Almonds, set close to the gullet in the end of the throat,

called also *Paristmia*, *Antiadēs*, *Tonsillæ* and *Salviares glandulæ*. FF. Another glandulous body in the midst of the gullet, about the fifth rack bone, from which place the gullet gives place to the great arterie, somewhat declining to the right side: *Vesalius*, *Lib. 5. Cap. 3.* and *Columbus Cap. ult. lib. 9.* write, that those Glandules are filled with a certain moisture, with which the gullet is moistened, that the meats may slide down more easily into the stomach, as through a slippery passage. No otherwise than the *Glandulæ prostate*, filled with a kind of gross and oily moisture, smooth the passage of the urine, that so it may flow through it, with a more free and less troubled course. G. the connexion of the gullet with the stomach, where the upper orifice of the stomach is fashioned. H. the lower orifice of the stomach called *Pylorus*. I. K. the upper part of the stomach at I. the lower at K. LL. the fore-side of the stomach. P. the gut called *Duodenum*. T. Y. a nerve on the left side creeping up to the top of the stomach, and so running out to the liver.

C H A P. XV.

of the Guts.

The Guts the instruments of distribution and expulsion, are of the same substance and composition with the stomach, but that the site of the coats of the stomach is contrary to those of the guts. For that which is the innermost coat of the stomach is the outermost of the guts, and so on the contrary. The figure of the guts is round, hollow and capacious, some more, some less, according to the divers bigness.

But for the quantity of the guts, some are small, some great, more or less, according to the variety of bodies. But they are six in number: for there be three small; the *Duodenum*, the *Jejunum*, or empty gut, and the *Ileon*. Three great, the Blind, the Colick, and the Right gut. All which have had their names for the following reasons; the first, because it is extended the length of twelve fingers, like another stomach, without any turning, or winding; of which greatness it is found in great bodied men, such as were more frequently to be met withall in *Galen's* time, than in this time of ours, in which this gut is found no longer than seven, eight, or nine fingers at the most. The cause of this length is, that there may be a free passage to the Gate-vein, coming out of the liver, as also to the artery and nerve which run into it. For seeing that this gut may sometimes rise to the top of the liver, it would possess the space under the bladder of the gall (with which it is often tinctured) if it had any revolutions that way, which is the passage for such like vessels. Others give another reason of this figure, which is, that there should be nothing to hinder the easie and fit distribution of the perfectly concocted *Chylus* to the liver.

The second is called *Jejunum*, or the empty gut, not because it is absolutely so, but because it contains little in comparison of the other. There is a triple cause of this emptiness, the first the multitude of the meseraick veins and arteries which are about it, whereupon there is a greater and quicker distribution of the *Chylus*. The second is the vicinity or neighborhood of the liver strongly drawing the *Chylus* contained in it; the third is the flowing down of the chollerick humor from the bladder of the Gall into it, which ever and anon by its acrimony cleanses away the filth, and by continuall flowing solicits it to expulsion. The third is called *Ileon* because it lies between the *Ilia* or flanks; it differs nothing from the rest in substance and magnitude, but in this one thing, that there is more matter contained in it than in the rest, by reason of the paucity of the vessels terminated in it, that it is no marvell that there can be no exact demonstration made of them. The fourth is called *Cacum* or the blind, because it hath but one passage to send out and receive in the matter. This gut hath a long and strait production, which according to the opinion of some (though altogether erroneous) often falls down into the *Scrotum* in the rupture, or relaxation of the Rim of the Belly; for that production in the lower belly strongly sticks to the *Peritonæum* or Rim, which hinders such falling down. But *Galen* seems by such a blind gut to have meant this long and narrow production, and certainly so thinks the common sort of Anatomists, but here *Vesalius* justly reprehended *Galen*. Wherefore *Sylvius* that he might free *Galen* of this fault, would have us by the blind gut to understand the beginning of the colick gut. The fifth is called *Colon* (or colick gut) because it is greater and more capacious than the rest. The sixth and last, the Right gut, by reason of the rightness or straightness of the passage. This, in beasts especially, hath a certain fatness in it to make the passage slippery, and lest the gut should be exulcerated in the passage, by the sharpness of hard and acrid excrements.

The site of these guts is thus: The *Duodenum* upon the backbone bends to the right hand; the *Jejunum* possesses a great part of the upper umbilicall region, diffuses it self into both sides with windings, like to these of the gut *Ileum*, even to the flanks. The gut *Ileon* is situate at the lower part of the umbilicall region, going with many turnings and windings, even to the hollownes of the holy-bone above the bladder and side parts of the *Hypogastrium*, they call the flanks.

The Blind bends to the right hand, a little below the kidney, above the first and fourth *Vertebra* of the loins. The *Colon* or Colick gut is crooked and bent, in the form of a *Scythian* bow, filling all the space from the blind gut, below the right kidney even to the hollownes of the liver, and then it goes by the gibbous part of the stomach above the small guts, even to the hollownes of the Spleen; from whence sliding under the left kidney, with some turnings, it is terminated upon the *Vertebra's* of the loins.

By all which turnings and windings of the colick gut, it is easie to distinguish the pain of the stone of the kidneys, which remain fixt in one certain place, from the colick wandring through these crooked passages we mentioned. The right gut tends with an oblique site towards the left hand, upon the holy bone even to the very fundament. They have all one and a common connexion; for they are all mutually joined together by their coats, because there is but one way from the gullet even to the fundament, but they are joined to the principall parts by their nerves, veins, and arteries.

But a more proper connexion is that, where the *Duodenum* on the upper part of it, is joined

ed with the *Pylorus*; but on the lower part to the *Jejunum*, and the parts lying under it, by the coat of the *Peritonæum*. The *Jejunum*, or empty gut, is joyned to the *Duodenum* and *Ileon*. The *Ileon* with the empty and blind guts. The blind with the *Ileon* and *Colon*, and with the right side of the backbone where it is tied more straitly. The *Colon* with the blind and right guts, and in his middle part, with the kidneys and gibbous part of the stomach; whereby it comes to pass, that being distended with wind in the colick, it overturns and presses the stomach, and so causes vomiting.

Why vomiting happens in the colick.

The *Sphincter* muscles of the fundament.

Gal. lib. 5. de usu partium. cap. 14.

Lastly, the right gut is annexed with the colick gut and fundament. At the end whereof there is a muscle fattened, of figure round and circular, called the *Sphincter*, arising from the lower *Vertebra's* of the holy bone and rump, by the benefit of which as of a dore or gate, the excrements are restrained at our wil, lest man born for all honest actions, without all shame, in every time and place, should be forced every where to ease his belly. For such as have lost the benefit of this muscle by the palsy, have their excrements go from them against their wills. There is a body situate at the end of the right gut, of a middle substance between the skin and flesh, as it were arising from the mixture of them both, like the extremities of the lips, of the same use with the *Sphincter*, but that it is not altogether so powerfull. But there are also certain veins situate about it called the *Hæmorrhoidall*, of which we will speak in their place.

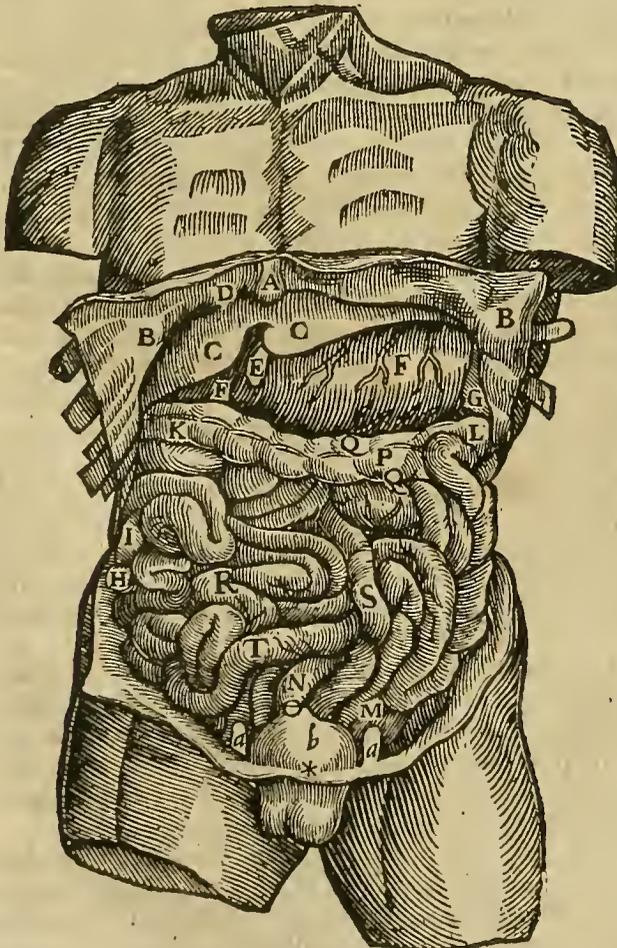

Besides there are two other muscles that descend to the end of this gut, being broad and membranous on each side, one arising from the side and inner parts of the share and hip-bones, which inserted above the *Sphincter* pull up the fundament falling down, wherefore they are called *Levatores Ani*, or the lifters up of the fundament. Wherefore when as either they are too weak, or resolved, or the fundament oppressed with the weight of flegmatick, salt, choleric and sharp humors, the gut is scarce restored into its place, that there is need of the help of the fingers for that purpose.

Levatores Ani.

The action of the guts.

The guts follow the temper of the stomach. Their action is the distributing the *Chylus* by the meseraick veins (which of duty belongs to the three small guts) and the receiving the excrements of the *Chylus*, and retention of them, till a fit time of expulsion, which belongs to the third quarter. Besides, these small guts finish up the work of concoction, begun in the stomach, although they be not altogether made for that use. But nature is often accustomed to abuse the parts of the body for some better use.

The fifth figure of the lower belly.

- A. The breast blade, *Cartilago, Ensiformis*.
- BB. The Rim, with the midriffe and broken ribs bent outwards.
- CC. the gibbous part of the liver.
- D. a ligament tying the liver to the midriffe.
- E. part of the umbilicall vein.
- FF. the stomach filld full of meat.
- G. a part of the spleen.
- H. the blind gut of the late writers, for the Ancients took the top of the *colon* for it.
- I. the beginning of the great or thick guts.
- I. and so to K. sheweth the passages of the colick gut from the right kidney to the liver. And so the colick and the stone on this side are in one place, and therefore hardly distinguished.
- K. to L. the same colick gut lyeth under the whole bottome of the stomach, which is the reason that those which are troubled with the colick cast so much.
- L. to M. The passage of the *Colon* from the spleen to the share bone, by the left kidney, a way, which maketh the pain of the stone and the Colick on the left side very

hard to distinguish. N. The *Colon* ending in the right gut. O. The beginning of the right gut unto the bladder. P. Q. The funken or fallen side of the *Colon* at P. and his Chambers or Cels at Q. R. S. T. The lesser guts especially lying under the Navel. a. a. The two umbilicall arteries. b. The bottome of the bladder. * The connexion of the bladder and the *Peritonæum*.

But we must note, that for the compofure of the guts, they have only tranfverfe fibers, for expulfions fake, unlefs that at the beginning of the *Colon*, and the end of the right gut, you may fee certain right fibers added to the tranfverfe to ftrengthen them, left thefe guts fhould chance to be broken and torn by the paffage of hard excrements, and the laborious endeavour of expulfion (fpecially in brute beafts.)

Their fibers.

But if any afke, how they have retention, being they want oblique fibers; he may know that the *feces* are retained in the right gut, by the force of the *Sphincter* mufcle, but oft times in the blind, by their hardnefs and abundance, whereby they flick in the paffage; but in the reft, by reason of their conformation into many windings and turnings. The length of the guts, is feven times more than the length of the whole body; to this length they have windings, left the nourifhment fhould quickly fide away, and left men fhould be withdrawn by gluttony from action and contemplation. For fo we fee it comes to pafs in moft beafts, which have one Gut, ftreched ftreight out from the ftomach to the fundament; as in the *Lynx* and fuch other beafts of infatiable gluttony, alwayes, like plants, regarding their food.

How the guts become fit to retain.

Their length.

CHAP. XVI.

Of the Mefentery.

After the Guts follows the Mefentery, being partly of a fatty and partly of a spermatick fubftance. The greatnefs of it is apparent enough, although in fome it be bigger, and in fome leffer according to the greatnefs of the body. It is of a round figure and not very thick. It is compofed of a double coat arifing from the beginning and root of the *peritoneum*. In the midft thereof it admits nerves from the *Coffall* of the fixt conjugation, veins from the *Vena Porta* or Gate vein; Arteries from the defcendent artery, over and befides a great quantity of fat and many glandulous bodies, to prop up the divifion of the veffels fpred over it, as alfo to moiften their fubftance. It is in number one, fituat in the middle of the guts, from whence it took its name. Yet fome divide it into two parts, to wit, into the *Meferium*, that is, the portion interwoven with the fmall guts, and into the *Mefocolon* which is joynd with the Great. It hath connexion by its veffels, with the principall parts, by its whole fubftance with the guts, and in fome fort with the kidneys, from whose region it feems to take its coats.

The fubftance, Magnitude.

Figure, Compofure.

Number, The connexion.

It is of a cold and moift temper, if you have refpect to his fatty fubftance; but if to the reft of the parts, cold and dry.

The temper.

The action and ufe of it is, to bind and hold together the guts, each in his place, left they fhould rafhly be folded together, and by the Meferaick veins (which they term the hands of the Liver) carry the *Chylus* to the liver.

The action and ufe.

In which you muft note, that all the Meferaick Veins come from the liver, as we understand by the diffection of bodies; although fome have affirmed, that there be fome veins ferving for the nourifhment of the guts, no wayes appertaining to the Liver, but which end in certain Glandulous bodies, difperfed through the Mefentery, of whose ufe we will treat hereafter.

All the mēferaick veins come from the liver.

CHAP. XVII.

Of the Glandules in generall, and of the Pancreas, or sweets-bread.

A glandule is a fimple part of the body, fometimes of a fpongy and foft fubftance, fometimes of a denfe and hard. Of the foft Glandules are the *Tonfille*, or Almonds, like in fubftance to blanched Almonds; the *Thymus*, *Pancreas*, *Testicles*, *Proftate*. But the denfe and hard are the *Parotides* and other like. The Glandules differ amongft themfelves, in quantity and figure, for fome are greater than other fome, and fome are round and others plain, as the *Thymus* and *Pancreas*.

Subftance of the glandules.

Quantity and figure.

Others are compounded of veins, nerves, arteries, and their proper flefh, as the Almonds of the ears, the milky glandules in the breasts and the testicles. Others want nerves, at leaft which may be feen, as the *Parotides*, the axillary, or thofe under the armholes and others. The number of glandules is uncertain, by reason of the infinite multitude and variety of sporting nature. You fhall find them alwayes in thefe places, where the great divifions of veffels are made; as in the middle ventricle of the brain, in the upper part of the *Chest*, in the *Mefentery* and other like places.

Composition.

Number.

Although otherfome be feated in fuch places, as nature thinks needfull to generate and caft forth of them a profitable humor to the creature; as the almonds at the root of the tongue, the kernels in the dugs, the spermatick veffels in the *scrotum* and at the fides of the wombe; or where nature hath decreed to make emunctories for the principall parts,

Connexion. as behind the ears, under the armholes, and in the groins. The connexion of glandules is not only with the vessels of the parts concurring to their composition, but also with those, whose division they keep and preserve. They are of a cold temper, wherefore Physitians say the blood *recrudescere* (i) to become raw again in the dugs, when it takes upon it the form of milk. But of these some have action, as the almonds, which pour our spatle usefull for the whole mouth, the dugs milk, the Testicles seed; others, use only, as those which are made to preserve, underprop and fill up the divisions of the vessels. Besides this we have spoken of glandules in generall, we must know that the *Pancreas* is a glandulous and flesh-like body, as that which hath every where the shape and resemblance of flesh. It is situate at the flat end of the liver, under the *Duodenum* with which it hath great connexion, and under the gate-vein, to serve as a bulwarke, both to it and the divisions thereof, whilst it fills up the empty spaces between the vessels themselves, and so hinders, that they be not pluckt asunder, nor hurt by any violent motion, as a fall or the like.

C H A P. XVIII.

Of the Liver.

What the liver is. Having gone thus far, order of dissection now requires, that we should treat of the distribution of the gate-vein; but because it cannot well be understood unless all the nature of the liver from whence it arises, be well known, therefore putting it off to a more fit place, we will now speak of the Liver. Wherefore the Liver (according to *Galens* opinion, *lib. de form. fetus*) is the first of all the parts of the body, which is finished in conformation, it is the shop and Author of the blood, and the originall of the veins; the substance of it, is like the concrete mud of the blood, the quantity of it is divers, not only in bodies of different, but also of the same species; as in men amongst themselves, of whom one will be gluttonous and fearfull, another bold, and temperate, or sober; for he shall have a greater liver than this, because it must conceive and concoct a greater quantity of *Chylus*: yet the liver is great in all men, because they have need of a great quantity of blood for the repairing of so many spirits and the substantifick moisture, which are resolved and dissipated in every moment by action and contemplation. But there may be a twofold reason given, why such as are fearfull have a larger liver. The first is, because in those the vitall faculty (in which the heat of courage and anger resides) which is in the heart, is weak; and therefore the defect of it must be supplied by the strength of the naturall faculty. For thus nature is accustomed to recompence that which is wanting in one part, by the increase and accession of another. The other reason is, because cold men have a great appetite, for by *Galens* opinion *In arte parva*, coldness increases the appetite; by which it comes to pass that they have a greater quantity of *Chylus*, by which plenty the liver is nourished and grows larger. Some beasts, as Dogs, and swine, have the liver divided into five or more Lobes, but a man hath but one Lobe, or two, or three at the most; and these not so much distinguished, as which cherish the upper and hollow region of the ventricle, with embracing to help forward the work of concoction. Therefore the liver is almost content with one Lobe, although it is alwayes rent with a small division, that the umbilicall vein piercing into the roots and substance of it, may have a free passage; but also oftentimes there is as it were a certain small lobe of the liver, laid under that umbilicall vein, as a cushion.

The figure. The figure of the liver is gibbous; rising up and smooth towards the Midriffe; towards the stomach is the *sinuous* or hollow side of it somewhat unequall, and rough by reason of the distance of the Lobes, the original of the hollow vein, and the site of the bladder of the Gall.

The composition. The composition of the liver is of veins, nerves, arteries, the coat and proper substance thereof which we call the gross and concrete blood, or *Parenchima*. Veins and arteeies come to it from the navill; but nerves immediately from these which are diffused over the stomach according to *Hippocrates*; yet they penetrate not very deep into its substance, for it seems not to stand in need of such exact sense, but they are distributed upon the coat and surface thereof, because this part made for distribution over the whole body, keeps to it self no acrid or malign humor; for the perception of which it should need a nerve, although the coat investing it, sends many nervous fibers into its substance, as is apparent by the taking away of the coat from a boiled liver; we must think the same of the other entrails. The coat of the liver is from the *Peritoneum*, waxing small from the umbilicall vein, when it divides it self for the generation of the gate and hollow veins, as is observed by *Galen*, *Lib. de format. Fetus*. The liver is only one; situate in the greater part on the right side, but with the lesser part on the left, quite contrary to the stomach. Its chief connexion is with the stomach and guts, by the veins and membranes of the *Peritoneum*; by the hollow vein and artery, with the heart; by the nerve with the brain, and by the same ligatures with all the parts of the whole body. It is of a hot and moist temper, and such as have it more hot, have large veins and hot blood; but such as have it cold, have small veins, and a discoloured

shew. The action of the Liver is the conversion of *Chylus* into the blood, the work of the second concoction. For although the *Chylus* entering into the meseraick veins, receive some resemblance of blood, yet it acquires not the form and perfection of blood, before it be elaborate, and fully concoct in the liver. It is bound and tyed with three strong ligaments, two on the sides in the midst of the bastard ribs, to bear up its sides, and the third more high and strong, descending from the breast-blade, to sustain its proper part, which with its weight would press the lower orifice of the stomach, and so cause a falling or drawing down of the sternon and collar bone. And thus much may suffice for its proper ligaments, for we before mentioned its common; the veins, arteries, nerves, and coat of the *Peritoneum*, by which it is knit to the loins and other naturall parts. But we must note, that besides these three proper ligaments, the liver is also bound with others to the bastard ribs; as *Sylvius* observes in his Anatomical observations, and *Hollerius* in his Practise, *Cap. de pluritide*.

The action.

The ligaments.

CHAP. XIX.

Of the bladder of the Gall.

Now we must come to the bladder of the Gall, which is of a nervous substance, and of the bigness of a small pear; it is of figure round, with the bottom more large, but the sides and mouth more narrow and strait. It is composed of a double coat, one proper, consisting of three sorts of fibers, the other from the *peritoneum*. It hath a vein from the *Porta* or gate-vein, and an artery from that which is diffused into the liver, and a nerve from the sixth conjugation. It is but one and that hid on the right side under the greater lobe of the liver, it is knit with the touching of its own body, and of the passages and channels made for the performance of its actions with the liver, and in like manner with the *Duodenum*, and not seldome with the stomach also, by another passage; and to conclude to all the parts by its veins, nerves, arteries, and common coat. It is of a cold temper, as every nervous part is. The action of it is to separate from the liver the cholerick humor, and that excrementitious, but yet naturall by the help of the right fibers, for the purifying of the blood, and by the oblique fibers, so long to keep it being drawn, untill it begin to become troublesome in quantity, or quality, or its whole substance, and then by the transverse fibers, to put it down into the *Duodenum* to provoke the expulsive faculty of the guts. I know *Fallopian* denies the texture of so many fibers, to be the minister of such action to the gall. But *Vesalius* seems sufficiently to have answered him. The bladder of the gall hath divers channells, for coming with a narrow neck, even to the beginning of the Gate-vein, it is divided into two passages, the one whereof suffering no division is carryed into the *Duodenum*, unless that in some it send another branch into the bottome of the stomach, as is observed by *Galen*; which men have a miserable and wretched life, being subject to cholerick vomitings, especially when their stomachs are empty, with great pains of their stomach and head, as is also observed by *Galen*, *Cap. 74. Artis Med.* The other coming out of the body of the liver divides it self into two or three passages, again entering the substance of the liver, is divided with infinite branches, accompanying so many branches of the Gate-vein through the substance of the liver, that so the blood unless it be most elaborate and pure, may not rise into the hollow vein, all which things Dissection doth manifestly teach.

CHAP. XX.

Of the Spleen or Milt.

The substance.	 <p>Ut because we cannot well shew the distribution of the gate-vein, unless the Spleen be first taken away, and removed from its seat: therefore before we go any further, I have thought good to treat of the Spleen. Therefore the Spleen is of a soft, rare, and spongy substance (whereby it might more easily receive and drink up the dregs of the blood from the liver) and of a flesh more black than the liver. For it resembles the colour of its muddy blood, from which it is generated. It is of an indifferent greatness; but bigger in some, than in other some, according to the diverse temper and complexion of men. It hath as it were a triangular figure, gibbous on that part, it sticks to the ribs and midriff, but hollow on that part next the stomach. It is composed of a coat, the proper flesh; a vein, artery, and nerve. The membrane comes from the <i>Peritonæum</i>, the proper flesh from the <i>fæces</i> or dregs of blood, or rather of the naturall melancholy humour, with which it is nourished. The fourth branch of the <i>vena porta</i>, or gate vein, lends it a vein; the first branch of the great descendent artery presently, after the first entrance without the Midriff, lends it an artery. But it receives a nerve, from the left costall, from the sixth conjugation on the inner part, by the roots of the ribs; and we may manifestly see this nerve, not only dispersing it self through the coat of the liver, but also penetrating with its vessels the proper flesh thereof, after the self same manner, as we see it is in the heart and lungs. It is one in number, situate on the left side, between the stomach and the bastard ribs, or rather the midriff which descends to their roots. For it oft times cleaves to the midriff, on its gibbous part, by a coat from the <i>Peritonæum</i>, as also on the hollow part to the stomach, both by certain veins which send it into the ventricle, as also by the kall. It hath connexion, either primarily, or secondarily, with all the parts of the body, by these its vessels.</p> <p>It is of a cold and drie temper; the action and use of it is to separate the melancholick humor, which being feculent and drossie, may be attenuated by the force of many arteries dispersed through its substance. For by their continuall motion, and native heat, which they carry in full force with them from the heart, that gross blood puts off its grossness, which the Spleen sends away by passages fit for that purpose, retaining the subtler portion for its nourishment. The passages by which it purges it self from the grossness of the melancholy blood, are a vein ascending from it into the stomach to stir up the appetite by its sournesse, and strengthen the substance thereof by its astriction; and also another vein, which sometimes from the Spleen branch, sometimes from the Gate-vein, plainly under its orifice, descends to the fundament, there to make the Hæmorrhoidall veins.</p>

CHAP. XXI.

Of the Vena Porta, and Gate-vein, and the distribution thereof.

The substance and figure. Composition. Number and Site.	 <p>The gate-vein, as also all the other veins, is of a spermatick substance, of a manifest largeness, of a round and hollow figure, like to a pipe or quill. It is composed of its proper coat, and one common from the <i>Peritonæum</i>. It is only one, and that situate in the firmous or hollow part of the liver, from whence it breaks forth (or rather out of the umbilicall vein) into the midst of all the guts, with which it hath connexion, as also with the stomach, spleen, <i>sphincter</i> of the fundament and <i>Peritonæum</i>, by the coat which it receives from thence. It is of a cold and dry temper. The Action of it is, to suck the <i>Chylus</i> out of the ventricle and guts, and so to take and carry it to the Liver, untill it may carry back the same turned into blood for the nutriment of the stomach, spleen and guts. This gate-vein coming out of the firmous part of the Liver, is divided into six branches, that is, four simple, and two compound, again divided into many other branches. The first of the simple ascends from the forepart of the trunk to the bladder of the Gall by the passage of the Choler (and are marked with <i>g. g.</i>) with a like artery for life and nourishment, and this distribution is knowne by the name of <i>Cysticæ gemellæ</i> or Cystick twins. The second is called the <i>Gastrica</i> or stomach vein, arising in like manner from the forepart of the trunk, is carried to the <i>Pylorus</i> and the firmous or back part of the stomach next to it.</p> <p>The third is called <i>Gastrepiplois</i>, the stomach and kall vein, which coming from the right side of the gate-vein goes to the gibbous part of the stomach next to the <i>Pylorus</i> and the right side of the kall.</p> <p>The fourth going forth from behind and on the right hand of the gate-vein, ascends above the root of the Meseraick branch even to the beginning of the gut <i>Jejunum</i>, along the gut <i>Duodenum</i>, from whence it is called <i>Intestinalis</i>, or the gut vein. And these are</p>
Temper and Action.	
Division thereof into 6 branches, of which 4 simple.	
1 <i>Cysticæ gemellæ</i>	
2 <i>Gastrica</i>	
3 <i>Gastrepiplois</i>	
4 <i>Intestinalis</i>	

are the foure simple branches. Now we will speak of the compound.

The first is the spleenick, which is divided after the following manner. For in its first beginning and upper part, it sends forth the *Coronalis*, or crowne vein of the stomach, which by the back part of the stomach ascends into the upper and hollow part thereof; to which place, as soon as it arrives, it is divided again into two branches, the one whereof climbs up even to its higher orifice, the other descends downe to the lower, sending forth by the way other branches to the fore and back parts of the stomach. These engirt and on every side incompass the body of the ventricle, for which cause they are named the crown veins.

I have sometime observed this coming forth of the trunk, a little above the orifice of the spleenick branch. But this same spleenick branch on its lower part, produces the branch of the Hæmorrhoidall veins, which descending to the fundament above the left side of the loines, diffuses a good portion thereof into the least part of the colick gut, and the right gut, at the end whereof it is often seen to be divided into five Hæmorrhoidall veins, sometimes more, sometimes less.

Silvius writes that the Hæmorrhoidall branch descends from the mesenterick, and truly we have sometimes observed it to have been so. Yet it is more sutable to reason, that it should descend from the spleenick, not only for that we have seen with our eyes that it is so, but also because it is appointed by nature for the evacuation of the excrementitious melancholick humor. But this same spleenick branch out of the middle almost of its upper part produces the third branch going to the gibbous part of the stomach, and the kall; they terme it the greater, middle and left *Gastrepiplois*. But on the lower part towards the spleen it produces the simple *Epiplois*, or kall-vein, which it diffuses through the left side of the kall. Moreover from its upper part, which touches the liver, it sends forth a short branch called *vas breve*, or *venosum*, to the upper orifice of the ventricle for stirring up the appetite.

We have oftentimes, and almost alwayes observed, that this venie vessell, which *Galen* calls *vas breve*, comes from the very body of the spleen, and is terminated in the midst of the stomach on the left side, but never pierces both the coats thereof. Wherefore it is somewhat difficult to find, how the melancholy juyce can that way be powred, or sent into the capacitie of the stomach. Now the spleenick branch, when it hath produced out of it those five fore-mentioned branches, is wasted and dispersed into the substance and body of the spleen.

Then follows another compound branch of the *vena porta*, called the mesenterick, which is divided into three parts; the first and least whereof goes to the blind gut and to the right and middle part of the colick-gut, divided into an infinite multitude of other branches. The second and middle is wasted in the *Ileon*; as the third and greater in the *Iejunum* or empty gut. It is called Mesenterick because it is diffused over all the Mesentery; as the spleenick is in the spleen. And thus much we have to say of the division of the gate vein, the which if at any time thou shalt find to be otherwise, than I have set downe, you must not wonder at it; for you shall scarce find it the same in two bodies, by reason of the infinite varietie of particular bodies, which (as the Philosophers say) have each their owne, or peculiar gifts. Our judgment is the same of other divisions of the vessels. Yet we have set down that which we have most frequently observed.

CHAP. XXII.

Of the originall of the Artery, and the division of the branch, descending to the naturall parts.

Hose things being thus finished and considered, the guts should be pulled away; but seeing that if we should do so, we should disturb and lose the division of the artery descending to the naturall parts; therefore I have thought it better to handle the division thereof, before the guts be pluckt away. Therefore we must suppose, according to *Galens* opinion, that as all the veins come from the liver, so all arteries proceed from the heart. This presently at the beginning is divided into two branches, the greater whereof descends downwards to the naturall parts upon the spine of the back, taking its beginning at the fifth *vertebra* thereof, from whence it goes into the following arteries. The first called the intercostall, runs amongst the intercostall muscles, and the distances of the ribs, and spinall marrow, through the perforations of the nerves on the right and left hand from the fifth true, even to the last of the bastard ribs.

This in going this progress makes 7. little branchings, distributed after the forementioned manner, and going forth of the trunk of the descendent over against each of the intercostall Muscles.

The second being parted into two goes on each side to the Midriffe, whence it may be called, or expressed by the name of the *Diaphragmatica* or *Phrenica*, (i) the midriffe artery. The third being of a large proportion, arising from the upper part of the arterie presently after it hath passed the midriffe, is divided into two notable branches, whereof one goes to the stomach, spleen, kall, to the hollow part of the liver and the gall; the other is sent forth to the

The originall of arteries. The division of the great descendent artery, is into these.

Phrenica.

³
Caliaca.

mesentery and guts after the same manner, as we said of the meseraick veins, wherefore it is called the *Celiacæ*, or stomach artery. But we must note, all their mouths penetrate even to the innermost coat of the guts, that by that means they may the better and more easily attract the *Chylus* contained in them.

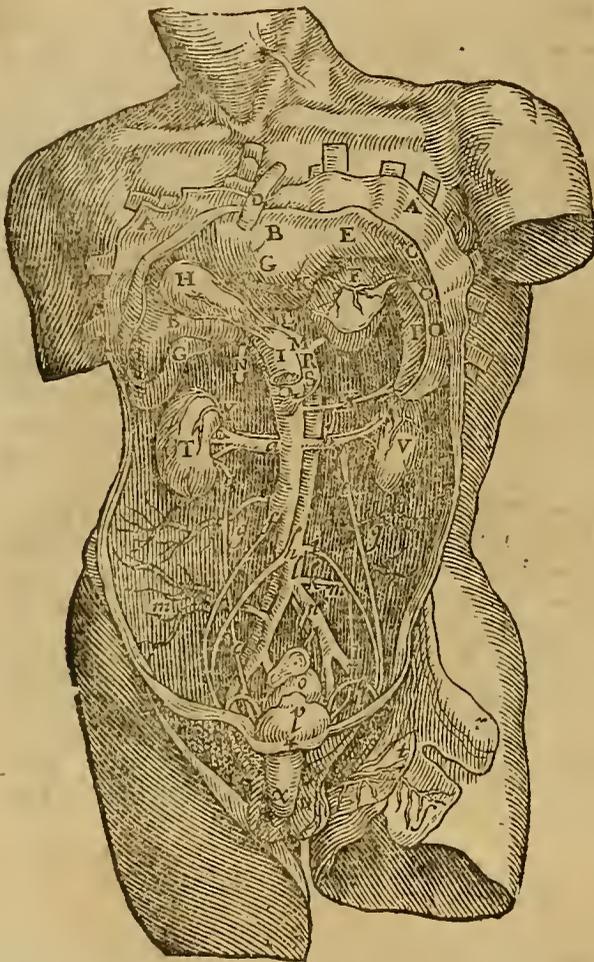

The fourth is carried to the reins, where it is named the Reinall or Emulgent, because it sucks fit matter from the whole mass of blood.

4.
Emulgent.

5.
Spermatica.

The fifth is sent to the testicles with the preparing Spermatick veins, whence also it is named the Spermatick Artery, which arises on the right side, from the very trunk of the descending Artery; that it may associate the spermatick vein of the same side, they run one above another, beneath the hollow vein, wherefore we must have a great care whilst we labour to lay it open, that we do not hurt and break it.

The seventh figure of the lower Belly.

- A, A, The midriff turned back with the ribs and the *peritonæum*.
 BB, The cave or hollow part of the liver, for the liver is lifted up that the hollow part of it may be better seen.

 E, The hollowness in the liver, which giveth way to the stomach.
 F, The left orifice of the stomach.
 G G, Certain knubs, or knots, and impressions in the hollow part of the liver.
 H, The bladder of gall.
 I, The Gate-vein, cut off, and branches which go to the bladder of gall.
 K, A nerve of the liver coming from the stomachicall nerve.
 L, An Artery common to the liver and bladder of gall.
 M, A Nerve common also to them both, coming from the right *costall* Nerve of the ribs.
 N, the passage of the Gall to the Guts cut off.
 O O, The hollow of the fore parts of the Spleen.
 P, The line where the vessels of the Spleen are implanted. Q, The trunk of the hollow vein. R, The trunk of the great Artery. S, The *Celiacall* Artery cut off. T, V, The Kidneys yet

wrapped in their membrane. X, Y, The fatty veins called *venæ adiposæ*. a, b, The Emulgent veins with the Arteries under them. c, d, d, The Ureter from either kidney to the bladder. e, f, The spermatick veins to the testicles, the right from the hollow vein, the left from the Emulgent. g, h, Veins coming from the spermatick to the *peritonæum*. h, i, the spermatick Arteries. k, The lower mesentericall Artery. l, The ascending of the great Artery above the hollow vein, and the division of it, and the hollow vein into two trunks. m, the Arteries of the loins called *lumbaris*. n, The holy Artery called *Sacra*. o, A part of the right gut. p, The bladder of Urine. * The connexion of the bladder with the *peritonæum*. q, A part of the vessels which lead the seed from the Testicles, is here reflected. r, s, the *scrotum*, or cod, that is, the skin that invests the yard and testicles. t, The fleshy pannicle or membrane which is under the cod. u, The coat which is proper to the testicles with his vessels. x, A part of the yard excoriated or flayed, and hanging down.

Hæmorrhoidalis
seu mesenterica
inferior.

The sixth going from the fore and upper part of this descending arterie, descends with the Hæmorrhoidall veins to the fundament; presently from his beginning, sending forth certain branches alongst the colick gut, which by *Anastomosis* are united with other branches of the *Celiacall* Arteries; for whosoever shall look more attentively, he shall often observe that veins are so united amongst themselves, and also Arteries, and sometimes also the veins with the Arteries. For an *anastomosis* is a communion and communicating of the vessels amongst themselves, by the application of their mouths, that so by mutuall supplies they may ease each others defects. But they call this the lower meseraick Artery.

7.
Lumbaris.

The seventh proceeding from the trunk with so many branches as there be *Verrebra's*

in the loines, goes to the loines and the parts belonging to them, that is, the spinall marrow of that part, and other parts encompassing these *Vertebra's*, whereupon it is stiled the *Lumbaris* or Loine Artery.

The eight maketh the Iliack arteries, untill such time as it departs from the *Peritonæum* *Iliaca* where the Crurall Arteries take their originall. This Iliack Artery sends many divarications towards the Holy bone where it takes its beginning, and to the places lying neer the Holy bone, which because they run the same course as the Iliack veins, for brevities sake, we will let pass further mention of them, till we come to treat of the Iliack veins.

C H A P. XXIII.

Of the distribution of the Nerves to the naturall parts.

TR remains, that before the bowels be taken away, we shew the nerves sent to the entrails and naturall parts, that as wise and provident men we may seem to have omitted nothing. First we must know that these nerves are of the sixt conjugation, which descend as well to the stomach all alongst the Gullet and the sides thereof, as those at the roots of the ribs on both sides within. But when they are passed through the Midriffe, those which are distributed amongst the naturall parts follow the turnings of the veins and arteries, but specially of the arteries. Wherefore if you have a mind to follow this distribution of the nerves, you must chiefly look for it in those places, in which the artery is distributed amongst the Guts above the loins.

The originall of the nerves which are carryed to the naturall parts.

These nerves are but small, because the parts serving for nutrition, needed none but little nerves, for the performance of the third duty of the nerves, which is in the discerning & knowing of what is troublesome to them. For unlesse they had this sense, there is nothing would hinder, but these bowels necessary for life, being possessed with some hurtfull thing, the creature should presently fall down dead; but we have this benefit by this sense, that as soon as any thing troubles and vellicates the bowels, we being admonished thereof may look for help in time.

Their magnitude and use.

And besides if they were destitute of this sense, they might be gnawn, ulcerated and putrefied by the raging acrimony of the excrements falling into and staying in them; but now (by means hereof) as soon as they find themselves pricked, or pluckt, presently by the expulsive faculty they endeavour to expell that which is troublesome, and so free themselves of present and future dangers.

C H A P. XXIII.

The manner of taking out the Guts.

WHEN the Guts are to be taken out, you must begin with the right Gut. And you must divide it, being first straitly tyed in two different places, at a just distance about four fingers from the end, with a sharp knife between the two ligatures. Then you must shew its proper coats, and fibers, and that common one which it hath from the *Peritonæum*. This being done, you must in like manner bind the trunk of the gate veine as neer the originall as you can; that so all his branches being in like manner tyed there may be no feare of effusion of blood: you must doe the like with the *Cœliack* Artery at the left Kidney, and in the lower *Mesenterick*, which descends to the right Gut with the *Hæmorrhoidall* veins. This being done, pull away the guts even to the *Duodenum*, which being in like manner tyed in two places, which ought to be below the insertion of the *Porus Cholagogus* or passage of the Gall, that you may shew the oblique insertion thereof into that gut, for the obliquity of its insertion is worth observation, as that which is the cause that the Gall cannot flow back into its bladder, by the compression of this Gut from below upwards. Then all these windings of the Guts may be taken away from the body.

CHAP. XXV.

The Originall and distribution of the descendent Hollow veine.

BECAUSE the rest of the naturall parts, do almost all depend upon the descendent Hollow vein, therefore before we goe any further, we will shew its originall and distribution. We said before that all veins proceeded from the Liver, but yet in divers places. For the gate vein goes out of the hollow part, and the hollow vein out of the Gibbous part of the liver, which going forth like the body of a tree, is divided into two great branches, the lesser of which goes to the vital & animal parts,

The originall of the hollow veine. It is divided into two trunkes.

Pudendæ.

and the extremities of these parts, as we shall shew in their place. The greater descending from the back part of the Liver above the *Vertebra's* of the loins to the parts beneath, goes in the manner following. The first division thereof is to the membranes of the reins, which come from the *Peritonæum*. Wherefore there it produces the *Venæ adiposæ*, or fatty veins, so called, because they bring forth a great quantity of fat in those places; Of these fatty veins, there is a diverse original, for the right doth oftentimes arise from the right emulgent, because it is higher; but the less comes from the very trunk of the hollow vein because the Emulgent on that side is lower, and you shall scarce see it happen otherwise.

The second being the Kidney or Emulgent veins, go to the Reins, which at their entrance, or a little before, is divided into two branches, like as the Artery is, the one higher, the other lower, and these again into many other through the substance of the Kidneys, as you may learn better by ocular inspection, than by book. They are thick and broad, that the serous humor may without impediment have freer passage. Their original is different, for the right Emulgent oftentimes comes forth of the hollow vein somewhat higher than the left; that seeing their office and duty is to purge the mass of blood from the cholerick and serous humor, that if any part thereof slide by the one, it may not so scape, but fall as it were into the other. Which certainly would not have happened if they had been placed the one just opposite to the other. For the serous or wheyish humor would have stayed as equally ballanced or poised, by reason of the contrariety of the action and traction, or drawing thereof. But we must remember that in dissecting of bodies, I have oft-times found in such as have been troubled with the stone, seven Emulgent veins and so many arteries; four from the left side coming from divers places, of which the last came from the Iliack; three from the right hand likewise in divers places.

The third division is called the Spermatick or seed vein, it goes to the Testicles; the original thereof is thus, that the right arises on the forepart of the trunk of the hollow vein; but the left most commonly from the Emulgent. Besides you shall sometimes find that these have companions with them, to the right Emulgent; but to the left, another from the hollow vein, in some but on one side, in others on both. But also I have sometimes observed the left emulgent to proceed from the spermatick or seed vein.

The fourth because it goes to the loins is called *Lumbaris*; which in his original and insertion is wholly like the Artery of the loins. But there are 4 *Lumbares* or Loin-veins on each side, that is, one in each of the 4 spaces of the 5 *Vertebra's* of the loins.

The fifth division makes the *Iliacæ*, untill passing through the *Peritonæum*, they take the names of Crural veins; These are first divided into the muscous, so called, because they goe to the oblique ascendent and transverse muscles, and to the *Peritonæum*. Sometimes they have their original from the end of the Trunk. And then the same *Iliacæ*, are divided into the *Sacræ*, or Holy; which goe to the spinall marrow of the Holy-bone, through those holes, by which the nerves generated of this marrow, have their passage.

Thirdly, the *Iliacæ* are divided into the *Hypogastricæ*, so called, because they were distributed to all the parts of the *Hypogastrium*, or lower part of the lower belly, as to the right Gut, the muscles thereof, the muscous skin, (in which place they often make the external *Hæmorrhoidall*, ordained for the purging of such blood as offends in quantity, as those other, [that is, the inward *Hæmorrhoidall*] which descends to the right Gut from the Gate-vein by the spleenick branch, serves for cleansing of that which offends in quality,) to the bladder and the neck thereof, even to the end of the yard, to the womb and even to the neck of the wombe and utmost parts of the privities, from whence it is likely the courses break forth in woemen with child and Virgins. But this same vein also sends a portion also without the *Epigastrium* by that perforation which is common to the share and haunch bones, which strengthened by meeting of the other internal Crural vein descends even to the Ham, but in the mean time by the way it is communicated to the muscles of the thigh called *Obturatores* and other parts within. Fourthly, the *Iliacæ* produce the *Epigastricæ* which on both sides from below ascend according to the length of the right muscles, spreading also by the way some branches to the oblique and transverse muscles and also to the *Peritonæum*. Fifthly, these produce *Iliacæ* the *Pudendæ* or veins of the privities, because they go in women to their privities, and into men to the Cods, where they enter that fleshy coat filled with veins, and go to the skin of the yard, they take their beginning under the *Hypogastricæ*.

CHAP. XXVI.

Of the Kidneys or Reins.

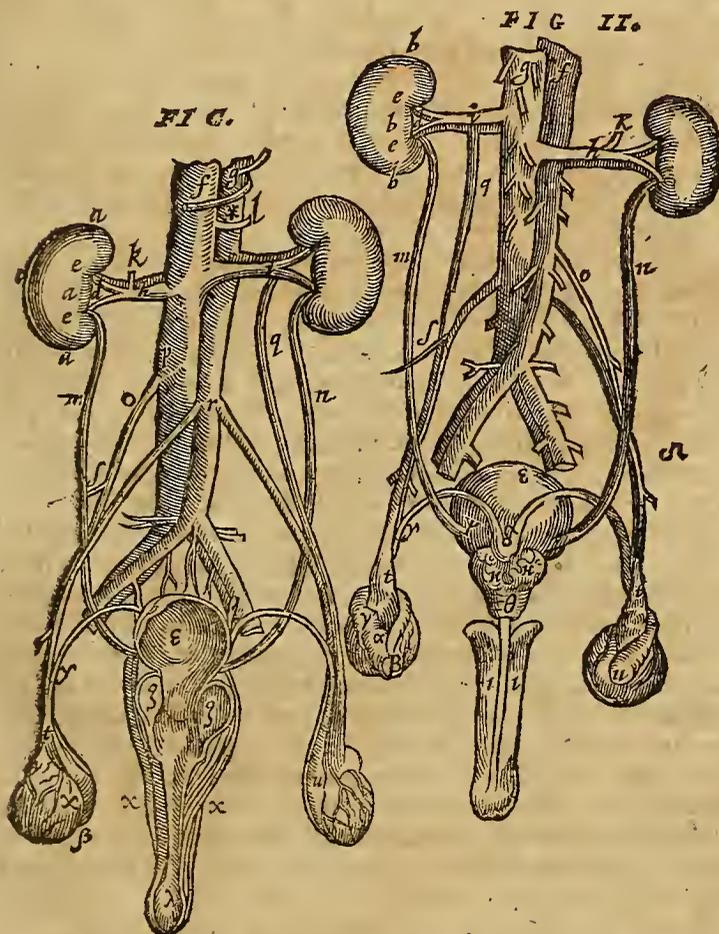

Now follow the Kidneys, which that they may be more easily seen, (after that you have diligently observed their situation) you shall dispoil of their fat, if they have any about them, as also of the membrane they have from the *Peritonæum*. First, you shall shew all their conditions, beginning at their substance.

The substance of the Kidneys is fleshy, dense and solid, lest they should be hurt by the sharpness of the urine. Their magnitude is large enough, as you may see. Their figure is somewhat long and round almost resembling a semicircle, and they are lightly flatted above and below. They are partly hollow and partly gibbous; the hollow lies next the hollow vein, and on this side they receive the Emulgent veins and Arteries, and send forth the Ureters, their gibbous part lies towards the loins. They are composed of a coat coming from the *Peritonæum*, their own peculiar flesh, with the effusion of blood about the proper vessels, (as happens also in other entrails) generates a small nerve, which springing from the *Coffall* of the sixth conjugation is diffused to each Kidney on his side into the coat of the kidney it self, although others think it always accompanies the vein and artery.

But *Fallopins* that most diligent Author of Anatomy hath observed, that this nerve is not only oftentimes divaricated into the coat of the kidneys, but also pierces into their substance.

Number.	<p>stance. They are two in number, that if the one of them should by chance be hurt, the other might supply those necessities of nature, for which the Kidneys are made. They lye upon the loyns at the sides of the great vessels, on which they depend by their proper veins and arteries; and they stick to them, as it were by a certain second coat, lest that they might be shaken by any violent motions. Wherefore we may say that the Kidneys have two coats, one proper adhering to their substance, the other as it were coming from the <i>Peritonæum</i> on that part they stick to it. The right Kidney is almost alwayes the higher, for those reasons I gave, speaking of the originall of the Emulgent vessels. <i>Columbus</i> seems to thinke the contrary, but such like controversies may be quickly decided by the Eye. They have connexion with the Principall vessels by the veins, nerves and arteries, by the coats with the loyns & the other parts of the lower belly, but especially with the bladder by the ureters. They are of a hot and moist temper, as all fleshy parts are. Their action is to cleanse the Masse of the blood from the greater part of the serous and cholerick humor. I said the greater part, because it is needfull that some portion thereof should go with the alimentary blood to the solid parts, to serve in stead of a vehicle, lest otherwise it should be too thick.</p> <p>Besides you must note that in each Kidney there is a cavity bounded by a certain membrane, incompassed by the division of the Emulgent veins and arteries, through which the urine is strained partly by the expulsive faculty of the Kidneys, partly by the attractive of the ureters, which run through the substance of the Kidneys on the hollow side, no otherwise than the <i>Porus chologogus</i> through the body of the Liver.</p>

CHAP. XXVII.

Of the spermatick Vessels.

Now we should have spoken of the ureters, because as we said before, they are passages derived from the Kidneys to carry the urine to the bladder. But because they cannot be distinguished and shewed unlesse by the corrupting and vitiating the site of the spermatick vessels; therefore I have thought it better to pais to the explication of all the spermatick parts.

And first of all you must gently separate them, (that so the declaration of them may be more easie and manifest) and that from the coat which comes from the *peritonæum*, and the fat which invests them even to the share-bone, having diligently considered their site before you separate them. Then you shall teach that the substance of these vessels, is like to that of the veins and arteries. Their quantity is small in thicknes, but of an indifferent length by reason of the distance of their originall from the Testicles. They are longer in men than in women, because these have their Testicles hanging without their belly, but women have them lying hid within their belly. Their figure and composure is wholly like the figure and composition of the veines and arteries, except in this one thing, that from that place where they goe forth of the great capacity of the *Peritonæum*, they are turned into many intricate windings, like crooked swollen veins, even to the Testicles. That the spermatick matter in that one tract, which yet is no other than blood, may be prepared to concoction, or rather be turned into seed in these vessels, by the irradiation of the faculty of the Testicles. These vessels are six in number, foure preparing, and two ejaculatory, of which we will speak hereafter. Therefore on each side there be two preparing vessels, that is, a vein and an artery, arising as we told you when we spoke of the distribution of the hallow vein. They are inserted into the Testicles through that coate which some call *Epididymis*, others *Dartion*. Their site is oblique above the loyns & flanks, whilest they run downe between the ends of the share and haunch bone, they are knit to the parts lying under them, both by certaine fibers which they send from them, as also by the membrane they have from the *Peritonæum*. They have like temperature as the veines and Arteries have. Their action is to carry blood to the Testicles, for generating of seed.

CHAP. XXVIII.

Of the Testicles, or Stones.

The Testicles are of a Glandulous, white, soft and loose substance, that so they may the more easily receive the spermatick matter: their magnitude and figure equall, and resemble a small pullets Egge somewhat flatted; their composure is of veins, arteries, coats and their proper flesh. Their veins and arteries proceed from the spermatick vessels, their nerves from the sixth conjugation, by the roots of the ribs and out of the holy bone. They are wrapped in foure coats, two whereof are common, and two proper. The common are the *Scrotum* or skin of the Cods, proceeding from the true skin; and the fleshy coat, which consists of the fleshy Pannicle in that place receiving a great number of vessels, through which occasion it is so called. The proper coats are first the *Erythroris* arising from the process of the *Peritonæum*, going into the *Scrotum* together

The coat

gether with the spermatick vessels which it involves and covers; this appears red both by reason of the vessels as also of the Cremaster muscles of the Testicles; Then the *Epididymis* or *Dartos* which takes its originall of the membrane of the spermatick preparing vessels. The flesh of the Testicles is as it were a certaine effusion of matter about the vessels, as we said of other entrails. But you must observe that the *Erythrois* encompasses the whole stone, except its head, in which place it sticks to the *Epididymis*, which is continued through the whole substance of the Testicle. This *Epididymis* or *Dartos* was therefore put about the stones, because the Testicles of themselves, are loose, spongius, cavernous and soft, so that they cannot safely be joined to the spermatick vessels, which are hard and strong. Wherefore Nature that it might join extreams by a fit *Medium* or mean, formed this coat *Epididymis*. This is scarce apparent in women by reason of its smallness. The two forementioned common coats, adhere or stick together by their vessels not only amongst themselves, but also with the *Erythrois*. You must besides observe the Cremaster muscles are of the said substance with other muscles, small and thin, of an oblique and broad figure, arising from the membrane of the *Peritonæum*, which (as we said before) assumes flesh from the flanks. Their composition is like that of other muscles. They are two, on each side one. They are situate from the ends of the flanks, even to the stones. They have connexion with the process of the *Peritonæum* and Testicles. Their temper is like that of other muscles. Their action is to hang and draw up the Testicles towards the belly, whence they are called hanging muscles. The Testicles are most commonly two in number; on each side one, sometimes there be three, sometimes one alone, as it happens also in the Kidnies; for some have but one Kidney. They lie hid in the *Scrotum* at the very roots of the share-bone, connexed to the principall parts of their vessels, with the neck of the bladder and yard; but by their coats they adhere to the parts from whence they have them. They are of a cold and moist temper, because they are glandulous; although they may be hot by accident, by reason of the multitude of the vessels flowing thither. Those whose testicles are more hot are prompt to venery, and have their privities and the adjacent parts very hairy, and besides their testicles are very large and compact. Those on the contrary that have them cold are slow to venery, neither do they beget many children, and those they get are rather female than male, their privities have little hair upon them, and their testicles are small, soft and flat.

The action of the testicles is to generate seed, to corroborate all the parts of the body, and by a certain manly irradiation to breed or encrease a true masculine courage. This you may know by Eunuchs or such as are *Gelt*, who are of a womanish nature, and are oftentimes more tender and weak than women. As *Hippocrates* teaches, by example of the *Scythians*; *lib. de Aere, locis & aquis*.

CHAP. XXIX.

Of the varicous bodies or *Parastatæ*, and of the ejaculatory vessels, and the glandulous or Prostates,

The varicous *Parastatæ* are nervous and white bodies, like as the nerves wound and close woven amongst themselves, they are stretched even from the top to the bottom of the testicles, from whence presently by their departure they produce the *Vasa ejaculatoria*, or leading vessels. But unless we doe very well distinguish their names, they shall scarce shun confusion. For that which I call *Parastatæ*; that is, as it were the head of the testicle, being as it were like another stone, is called *Epididymis* by *Galen. lib. 1. de semine*. But I by the example and authority of many Anatomists, understand by the *Epididymis* the proper coat of the testicles, of which thing I thought good by the way to admonish you of. Their Action is by their crooked passages to hinder the seed from departing out of the preparing into the leading vessels before it shall bee most perfectly laboured and concocted in these vessels by the power and force of the testicles. For in the first windings, the blood looks pure; but in the last it is not so red, but somewhat whitish. For Nature commonly doth thus delay the matter in its passage either by straitness, or obliquity, which it desires to make more perfect and elaborate by any new concoction; this we may learn by the foldings of the *Rete mirabile*, the windings of the Guts, the wrinkles in the bottome of the stomach, the straitness of the *Pylorus*, the capillary veins dispersed through the body of the Liver, certainly nature hath intended some such thing in the making of the spermatick vessels. Their quantity is visible, and figure round, tending somewhat to sharpness. They are composed of veins, nerves, and arteries, which they enjoy from the vessels of the testicles, from the *Epididymis*, or the coat, from the *Peritonæum* and their proper substance. Their temper is cold and dry. They bee two in number, one to each testicle. But these varicous bodies are called *Parastatæ*, *Assistens*, because they superficially assist, and are knit to the testicles according to their length, or long wayes. Out of the *Parastatæ* proceed the *Vasa ejaculatoria*, or leading vessels, being of the same substance as their Progenitors; that is, solid, white and as it were nervous. Their quantity is indifferent, their figure round, and hollow, that the seed may have a free passage through them, yet they seem not to bee perforated by any manifest passage, unless

unless by chance in such as have had a long *Conorrhœa*. They have like temper as the *Parastates*, between which and the *Prostates* they are seated, immediately knit with them both; as both in the coat and the other vessels with the parts from whence they take them.

But we must note, that such like vessels coming out of the *parastates* ascend from the bottom of the stones even to the top, in which place meeting with the preparing vessels, they rise into the belly by the same passages, and bind themselves together by nervous fibers, even to the inner capacity of the belly; from whence turning back, they forsake the preparing, that so they may run to the bottom of the share-bone, into the midst of two glandulous bodies which they call *prostates* situate at the neck of the bladder, that there meeting together they may grow into one passage.

The tenth figure, wherein those things shewed in the former figure, are more exactly set forth.

 qq, The ureters that go unto the bladder.
 r, u, The right spermaticall vein which ariseth near to u. x, y, The

double originall of the left spermaticall vein. x. from the emulgent. y, from the hollow vein. w, The originall of the spermaticall arteries. β, Certain branches from the spermaticall arteries which run unto the *Peritoneum*. γ, The passage of the spermaticall vessels through the productions of the *Peritoneum*, which must be observed by such as use to cut for the Rupture. δ, The spiry bodden bodies entrance into the testicle, it is called *Corpus varicosum pyramidale*. ε, The *Parastata*. ζ, The stone or testicle covered with his inmost coat. η, The descent of the leading vessell called *Vas deferens*. V γ, The Bladder. * The right gut. ξ, The glandules called *prostate* into which the leading vessels are inserted. ρ, The muscle of the bladder. στν, Two bodies of the yard, σ, and τ, and υ, his vessels. φχ, The coat of the Testicle. ↓α, The muscle of the Testicle ↓, hit vessels ω.

For thus of three passages, that is, of the 2 leading vessels, and 1 passage of the bladder, there is one common, one in men for the casting forth of seed and urine. A Caruncle rising like a crest at the beginning of the neck of the bladder argues this uniting of the passages; which receiving this same passage which is sufficiently large, is oft-times taken by such as are ignorant in Anatomy for an unnatural Caruncle, then especially when it is swollen through any occasion. These leading vessels are two in number, on each side one. Their action is to convey the seed made by the testicles to the Prostate, & so to the neck of the bladder, so to be cast forth at the common passage. But if any ask whether that common passage made by the two leading vessels between the two glandulous bodies be obvious to sense or no: We answer, it is not manifest, though reason compell us to confess that that way is perforated by reason of the spermatick, gross and viscous matter carryed that way. But peradventure the reason why that passage cannot be seen is, because in a dead carcass all small passages are closed and hid, the heat and spirits being gone, and the great appear much less, by

Their number
and action.

by reason all the perforations fade, and fall into themselves. Yet certainly these passages must needs be very strait, even in a living man, seeing that in a dead they will not admit the point of a needle. Wherefore we need not fear, lest in searching, whilst we thrust the *Catheter* into the bladder, it penetrate into the common passage of the leading vessels which runs within the Caruncle, unless peradventure by some chance, as a *Gonorrhœa*, or some great *Phlegmon*, it be much dilated besides nature. For I have sometimes seen such passages so open, that they would receive the head of a Spathern; which thing should admonish us, that in searching we take great care, that we do not rashly hurt this Caruncle, for being somewhat rashly handled with a *Catheter* it casts forth blood, especially if it be inflamed. But also the concourse of the spirits flowing with great violence together with the seed, much helps forward such ejaculation thereof performed through these strait passages by the power of the imaginative faculty in the Act of generation.

After the leading vessels follow the *Prostata*, being glandulous bodies of the same substance and temper that other Glandules are. Their quantity is large enough, their figure round, & somewhat long, sending forth on each side a soft production of an indifferent length. They are composed of veins, nerves, arteries, a coat (which they have from the neighbouring parts) and lastly their proper flesh, which they have from their first conformation. They are two in number, situate at the root of the neck of the bladder, somewhat straitly bound or tyed to the same, to the leading vessels, and the parts annexed to them. But alwayes observe; that every part which enjoyes nourishment, life and sense, either first or last hath connexion with the principall parts of the body, by the intercourse of the vessels which they receive from thence.

The use of the Prostates is, to receive in their proper body the seed laboured in the testicles, and to contain it there, untill it be troublesome either in quantity or quality, or both. Besides they contain a certain oily and viscid humor in their glandulous body, that continually distilling into the passage of the urine, it may preserve it from the acrimony & sharpness thereof. But we have observed also on each side other Glandules, which *Rondeletius* calls *Appendices glandulosæ*, Glandulous dependences to arise from these prostates, in which also there is seed reserved.

This Caruncle must be observed and distinguished from a *Hypercarcosis* or fleshy excrecence.

CHAP. XXX.

Of the Ureters.

Now it seems fit to speak of the *Ureters*, bladder and parts belonging to the bladder. Therefore the Ureters are of a spermatick, white, dense and solid substance, of an indifferent bignes in length and thicknes. Their figure is round and hollow. They are composed of two coats, one proper, consisting of right and transverse fibers, which comes from the emulgent veins and arteries; the other common, from the *Peritonæum*; besides they have veins, nerves and arteries from the neighbouring parts.

They be two in number, on each side one; they are situate between the Kidneys (out of whose hollow part they proceed) and the bladder. But the manner how the Ureters insert or enter themselves into the bladder, and the *Porus Chologogus* into the *Duodenum*, exceeds admiration; for the ureters are not directly but obliquely implanted near the orifice of the bladder, and penetrate into the inner space thereof; for within they doe as it were divide the membrane or membranous coat of the body of the bladder, and insinuate themselves into that, as though it were double. But this is opened at the entrance of the urine, but shut at other times, the cover as it were falling upon it, so that the humor which is fallen into the capacity of the bladder cannot be forced or driven back, no not so much as the aire blown into it can come this way out, as we see in swines bladders blown up and filled with aire.

For we see it is the Aire contained in these which fills them thus, neither can it be pressed forth but with extraordinary force.

For as this skin or coat turned in by the force of the humor gives way, so it being pressed out by the body contained within, thrusts its whole body into the passage as a stopple; like to this is the insertion of the *Porus Chologogus* into the Guts.

The ureters have connexion with the above mentioned parts, with the muscles of the loins; upon which they run from the Kidneys to the bladder.

Wherefore nothing hinders, but that the stone sliding through the ureters into the bladder, may stupefie the thigh as much as it did when it was in the Kidney. They are of a cold and dry temper.

Their use is, to serve as passages, or channels for carrying the urine into the bladder.

Temper and use.

CHAP. XXXI.

Of the Bladder.

The bladder is of the same substance that the ureters, that is, nervous, that so it may be the more easily dilated.

It is of a large proportion, in some bigger, in some lesse, according to the difference of age, and habit of body. It is of a round figure and as it were Pyramidall.

The substance

Figure,

Composition.

It is composed of the two coats, one proper, which is very thick and strong, composed of the three sorts of fibers, that is, in the inner side of the direct; without of the transverse; and in the midst of the oblique. The other common Coat coming from the *Peritonæum* hath veins and arteries on each side one, from the *Hypogastrick* vessels above the holy-bone, also it hath nerves on each side from the sixth conjugation mixt with the nerves of the holy-bone.

For these nerves descend from the brain even to the end of the holy-bone.

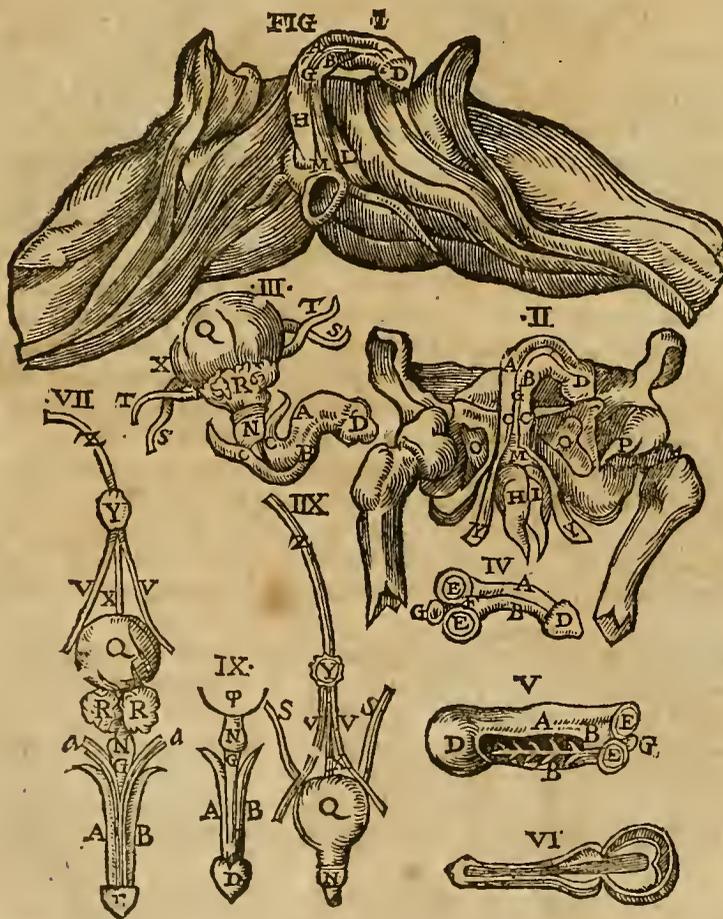

It is but one and that situate in men in the lower belly upon the right gut and below the share-bone, but in women between the womb and that bone, to which it cleaves with its membranous ligaments, as it doth to the yard by its neck, and to the right gut by its common coat and proper vessels. It is of a cold and dry temper.

Temper, use or action.

The use and action thereof is by the fibers continually to draw the urine, and contain it as long as need requires, and then to expell it by the neck, partly by compression either of it self, or rather to the muscles of the *Epigastrium* and midriff, because this motion, seeing it is voluntary cannot be performed unless by a muscle which the bladder wants; partly by the dilatation and relaxation of the Sphincter muscle composed of transverse fibers, like the sphincter of the fundament, after the same manner to shut up the orifice of the bladder, that the urine flow not out against our will. But the bladder as it fills is dilated, but as it is emptyed, it is contracted like a purse. You may easily observe this Muscle in a Sow's bladder, it is stretched from the orifice of the bladder and beginning of the urinary passage even to the privities even in women; but in men it is terminated in the *Peritonæum* as soon as it hath left the right Gut. Besides, this muscle is thus far stretched forth, that the urine by its compression should be wholly pressed out of the bladder, which by too long stay would by its acrimony do some harm. This is the common opinion of Anatomists concerning the Sphincter of the bladder, which nevertheless *Fallopious* allows not of. For (saith he) if this muscle should be situate beneath the glandulous bodies, the seed in copulation could never be cast forth without some small quantity of urine. Wherefore he thinks that this muscle is situate above the *Prostata*, and that it is nothing else but the beginning of the neck of the bladder, which becomes more fleshy whilst it is woven with transverse fibers.

Their Sphincter of the bladder.

RR, 3, 7, the *Prostata*, which into seed when it is perfectly laboured, is led. SS, 3, 8, Portions of the ureters. TT*, 3, Portions of the vessels, which lead down the seed. VV, 7, 8, the umbilicall arteries. X, 7, 8, the ligament of the bladder cald *Urachus*. Y, 7, 8 the navil or *umbilicus*. Z, 7, 8, the umbilicall vein. aa, 7, the vein and artery of the yard. b, 5, the artery distributed through the body of the yard.

For

For the neck of the bladder it differs nothing in substance, compofure, number, and temper from the bladder, but only in quantity, which is neither fo large, nor round in figure, but fomewhat long together with the yard representing the fhape of the letter S. It is placed in men at the end of the right Gut and *Perineum*, rifing upwards even to the roots of the yard, and with it bending it felf downwards; in women it is fhort, broad, and ftreight, ending at the orifice of the neck of the womb between the nervous bodies of the *Nymphæ*.

The neck of the bladder.

In men it hath connexion with the bladder, the ejaculatory veffels, the right gut and yard, but in women only with the neck of the wombe and privities. The ufe of it is in men to caft forth feed and urine, in women only urine. But we muft note that the fhare bones muft be divided and pulled afunder, in that part where they are joynd, that fo you may the more exactly obferve the fituation of thefe parts. Befides you muft note that by the *Perineum* we underftand nothing elfe, in men and women, then that fpace which is from the fundament to the privities, in which the feam is called *Taurus*.

The connexion and ufe thereof.

CHAP. XXXII.

Of the Yard.

Now follows the declaration of the Privy parts of men and women, and firft we will treat of mens. The yard is of a ligamentous fubftance, becaufe it hath its originall from bones, it is of an indifferent magnitude in all dimensions, yet in fome bigger, in fome lefs; the figure of it is round, but yet fomewhat flatted above and beneath.

The fubftance, quantity and figure of the yard.

It is compofed of a double coat, nerves, veins, arteries, two ligaments, the paffage of the urine, and four mufcles. It hath its coats both from the true fkin, as alfo from the flefhy pannicle, but the veins and Arteries from thefe of the lower part of the lower belly which run on the lower part of the Holy-bone into the yard, as the feminary veffels run on the upper part.

Compofure.

The ligaments of the yard proceed on both fides from the fides and lower commiffure of the fhare-bones; wherefore the yard is immediately at his root furnifhed with a double ligament, but thefe two prefently run into one fpongy one. The paffage of the urine fittuate in the lower part of the yard comes from the neck of the bladder between the two ligaments.

The ligaments.

For the four mufcles, the two fide ones compofing or making a great part of the yard, proceed from the inward extuberancy of the Hip-bone, and prefently they are dilated from their originall; and then grow lefs again. The two other lower arife from the mufcles of the fundament and accompany the urinary paffage the length of the *perineum* untill they enter the yard; but thefe two mufcles cleave fo clofe together, that they may feem one having a triangular form.

The mufcles.

The action of thefe four mufcles in the act of generation is, they open and dilate this common paffage of urine and feed, that the feed may be forcibly or violently caft into the field of nature; and befides they then keep the yard fo fuffe, that it cannot bend to either fide.

Their Action.

The yard is in number one, and fittuate upon the lower parts of the fhare-bone, that it might be more fuffe in erection. It hath connexion with the fhare-bone and neighbouring parts; by the particles of which it is compofed. It is of a cold and dry temper. The action of it is to caft the feed into the womb, for prefervation of mankind.

The head of it begins where the tendons end, this head from the figure thereof is called *Glans* and *Balanus*; that is, the Nut, and the fkin which covers that head is called *Preputium*; that is, the foreskin. The flefh of this *Glandule* is of a middle nature between the glandulous flefh and true fkin. But you muft note that the Ligaments of the yard are fpongy contrary to the condition of others, and filled with grofs and black blood. But all thefe ftirred up by the delight of defired pleafure, and provoked with a venereall fire, fwell up and erect the yard.

The Nut.

The *Preputium*, or foreskin.

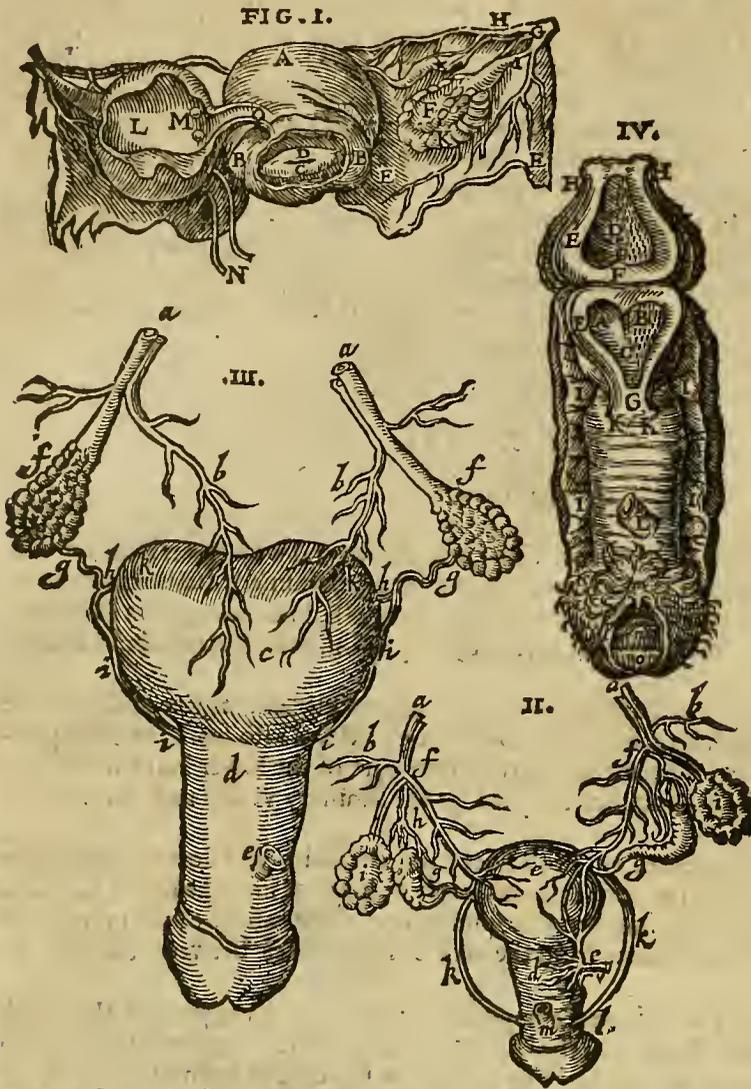

CHAP. XXXIII.

Of the Spermatick veffels and tefticles in women.

Now we fhould treat of the Privy parts in women, but becaufe they depend upon the neck and proper body of the womb, we will firft fpeak of the womb, having firft declared what difference there is between the Spermatick veffels and tefticles of men and women. Wherefore we muft know that the Spermatick veffels in women do nothing differ from thofe in men in fubftance, figure, compofure, number, connexion, temper, originall and ufe; but only in magnitude and diftribution, for women have them more large and fhort.

In what the Spermatick veffels in women differ from thofe in men.

The twelfth Figure, of the Womb.

- A. The bottome of the womb laid open without any membrane.
- BB. the neck of the womb turned upward.
- CD. a part of the bottome of the womb like the nut of the yard, swelling into the upper part of the neck of the womb, in the middle whereof the orifice appeareth.
- EE. a membrane knitting the womb to the *Peritoneum*, & holding together the vessels thereof.
- F. the left testicle.
- G. the spermaticall vein and artery.
- Ha part of the spermaticall vessels reaching unto the bottome of the womb.
- I. one part of the vessels coming to the testicles * a vessell leading the seed unto the womb.
- K. the coat of the testicle with the implication of the vessels. L. the cavity of the bladder opened. M. the insertion of the Ureters into the bladder. N. the Ureters cut from the kidneys. O. the insertion of the neck of the bladder into the lap or privity.

The second Figure.

aa. The spermaticall vein and artery. bb. branches distributed to the *Peritoneum* from the spermaticall vessels. c. the bottome of the womb. d. the neck of the womb. e. certain vessels running through the inside of the womb, and the neck thereof. ff. vessels reaching to the bottome of the womb produced from the spermaticall vessel. gg. the leading vessell of the seed called *Tuba*, the Trumpet. hh. a branch of the spermaticall vessel compassing the Trumpet. ii. the testicles. kk. the lower ligaments of the womb, which some call the *Cremasters* or hanging muscles of the womb. l. the lap or privity into which the *Cremasters* do end. m. a portion of the neck of the bladder.

The third Figure.

aa. The spermaticall vessels. bb. a branch from these spermaticall vessels to the bottome of the womb. cc. the body or bottome of the womb. d. the neck of the same. e. the neck of the bladder ending into the neck of the womb. ff. the testicles. gg. the leading vessels, commonly though not so well called the ejaculatory vessels. hh. the division of these vessels, one of them determining into the horns at double kk. ii. the other branch ending in the neck, by which women with child avoid their seed. kk. the horns of the womb.

The fourth Figure.

AB. The bosome of the bottome of the womb, at whose sides are the horns. CD. a line like a future or seam, a little distinguishing that bosome. EE. the substance of the bottome of the womb, or the thickness of his inner coat. F. a protuberation or swelling of the womb in the middle of the bosom. G. the orifice of the bottome of the womb. HH. the coat or second cover of the bottome of the womb, coming from the *Peritoneum*. IIII. a portion of the membranes which tie the womb. KK. the beginning of the neck of the womb. L. the neck of the bladder inserted into the neck of the womb. m. the *Clitoris* in the top of the privity. n. the inequality of the privity where the *hymen* is placed. o. the hole or passage of the privity in the cleft. p. the skinny caruncle of the privity.

Why womans spermatick vessels they are larger, but shorter then mens.

It was fit they should be more large, because they should not only convey the matter fit for generation of young and nourishment of the testicles, but also sufficient for the nourishment of the womb and child; but shorter, because they end at the testicles and womb within the belly in women. Where you must note that the preparing spermatick vessels,

fels, little before they come to the Testicles are divided into two unequal branches, of which the lesser bended, after the same manner as we said in men, goes into the head of the testicle, through which it sends a slender branch into the coats of the testicles for life and nourishment, and not only into the coats but also into leading vessels. But the bigger branch descends on each side by the upper part of the wombe between the proper coat and the common, from the *Peritonæum* where it is divided into divers branches. By this difference of the spermatick vessels you may easily understand why women cast forth less seed than men.

For their Testicles, they differ little from mens but in quantity; For they are lesser and in figure more hollow and flat, by reason of their defective heat which could not elevate or lift them up to their just magnitude. Their composure is more simple; for they want the *scrotum* or cod, the fleshy coat, and also according to the opinion of some the *Erythroides*; but in place thereof they have another from the *Peritonæum* which covers the proper coat, that is, the *Epididymis*, or *Dartos*. *Silvius* writes that womens Testicles want the *Erythroides*; yet it is certain that besides their peculiar coat *Dartos*, they have another from the *peritonæum*, which is the *Erythroides*, or as *Fallopian* calls it the *Elythroides*, that is as much as the *vaginalis* or sheath: But I think that this hath sprung from the mis-understanding that place in *Galen* where he writes, that womens testicles want the *Epididymis*. For we must not understand that to be spoken of the coat, but of the varicous parastrats (as I formerly said). They differ nothing in number, but in site; for in men they hang without the belly at the share bone above the *Peritonæum*; women have them lying hid in their belly, neer the bottome at the sides of the wombe, but yet so as they touch not the body of the wombe.

But these testicles are tyed to the womb both by a coat from the *Peritonæum*, as also by the leading vessels descending to the horns of the wombe, but to the rest of the body by the vessels and the nerves arising from the holy bone and Costall nerves. They are of a colder Temper than mens. The ejaculatory, or leading vessels in women differ thus from mens, they are large at the beginning, and of a veiny consistence, or substance, so that you can scarce discern them from the coat *Peritonæum*, then presently they become nervous, and waxe so slender, that they may seem broken or torn, though it be not so; but when they come nearer to the horns of the wombe, they are again dilated; in their other conditions, they agree with mens, but that they are altogether more slender and short. They have a round figure, but more intricate windings than mens; I beleeve, that these windings might supply the defect of the varicous Parastrats. They are seated between the testicles and wombe, for they proceed out of the head of the testicle, then presently armed with a coat from the *Peritonæum*, they are implanted into the wombe by its horns.

In what their testicles differ from mens.

C H A P. XXXIII.

Of the Wombe.

The Wombe is a part proper only to women, given by nature in stead of the *Scrotum*, as the neck thereof, and the annexed parts in stead of the yard; so that if any more exactly consider the parts of generation in women and men, he shall find that they differ not much in number, but only in situation and use. For that which man hath apparent without, that women have hid within, both by the singular providence of nature, as also by the defect of heat in women, which could not drive and thrust forth those parts, as in men. The womb is of a nervous and membranous substance, that it may be more easily dilated and contracted, as need shall require.

The magnitude thereof is divers, according to the diversity of age, the use of venery, the flowing of their courses, and the time of conception. The wombe is but small in one of unripe age, having not used venery, nor which is mensfrous; therefore the quantity cannot be rightly defined.

The figure of the wombe is absolutely like that of the bladder, if you consider it without the productions, which *Herophilus* called horns, by reason of the similitude they have with the horns of Oxen at their first coming forth. It consists of simple and compound parts. The simple are the veins, arteries, nerves, and coats. The veins and arteries are four in number, two from the preparing spermatick vessels, the two other ascend thither from the *Hypogastrick*, after this manner.

First, these vessels before they ascend on each side to the wombe, divide themselves into two branches, from which other some go to the lower part of the wombe, other some to the neck thereof, by which the mensfrous blood, if it abound from the conception, may be purged.

Nerves come on both sides to the wombe, both from the sixth conjugation, descending by the length of the back bone, as also from the holy bone, which presently united and joyned together, ascend and are distributed through the wombe, like the veins and arteries.

The utmost or common coat of the wombe, proceeds from the *Peritonæum*, on that part

Where in the privy parts, in women differ from those in men.

The substance and magnitude of the wombe.

Figure. The horns of the wombe. Composure. The veins and Arteries.

Nerves.

The Coats.

part it touches the holy bone; but the proper it hath from the first conformation, which is composed of the three sorts of fibers, of the right on the inside of the attraction of both seeds; the transverse without to expell, if occasion be; the oblique in the midst for the due retention thereof.

No cels in the wombe.

The wombe admits no division, unless into the right and left side, by an obscure line or seam, such as we see in the *scrotum*, but scarce so manifest; neither must we after the manner of the ancients, imagine any other cels in the wombe. For by the law of nature, a woman at one birth can have no more than two. An argument hereof is, they have no more than two dug. If any chance to bring forth more, it is besides nature, and somewhat monstrous, because nature hath made no provision of nourishment for them.

The site.

Nature hath placed the wombe at the bottome of the belly, because that place seems most fit to receive seed, to carry and bring forth the young. It is placed between the bladder and right gut, and is bound to these parts much more straitly by the neck, than by the body thereof; but also besides it is tyed with two most strong ligaments on the sides, and upper parts of the sharebone, on which it seems to hang; but by its common coat from the *Peritonæum*, chiefly thick in that place, it is tied to the hollow bone, and the bones of the hanch and loins.

The temper and action.

By reason of this strait connexion, a woman with child feeling the painfull drawings back, and as it were convulsions of those ligaments, knows her self with child. It is of a cold and moist temper, rather by accident, than of it self. The action thereof is to contain both the seeds, and to cherish, preserve, and nourish it, so contained, untill the time appointed by nature; and also besides, to receive, and evacuate the menstrous blood. The compound parts of the wombe are, the proper body and neck thereof. That body is extended in women big with child, even to the navell, in some higher, in some lower.

The Cotyledons.

In the inner side the *Cotyledones* come into our consideration, which are nothing else than the orifices and mouths of the veins, ending in that place. They scarce appear in women, unless presently after child-bearing, or their menstruall purgation; but they are apparent in sheep, Goats, and Kine, at all times like wheat corns, unless when they are with young, for then they are of the bigness of hassell nuts: but then also they swell up in women, and are like a rude peece of flesh of a finger and a half thick; which begirt all the naturall parts of the infant shut up in the wombe; out of which respect this shapeles flesh, according to the opinion of some, is reckoned amongst the number of coats investing the infant, and called *Chorion*, because, as in beasts, the *Chorion* is interwoven with veins, and arteries, whence the umbilicall vessels proceed; so in women this fleshy lump is woven with veins, and arteries, whence such vessels have their originall. Which thing, how true and agreeable to reason it is, let other men judg.

Columbus justly reproved.

There is one thing whereof I would admonish thee, that as the growth of the *Cotyledones* in beasts are not called by the name of *Chorion*, but are only said to be the dependents thereof, so in women such swollen *Cotyledones* merit not the name of *Chorion*; but rather of the dependences thereof.

The orifice of the wombe. The proper orifice of the wombe is not alwayes exactly shut in women with child. The neck of the wombe.

This body ends in a certain straitness which is met withall, in following it towards the privities, in women which have borne no children, or have remained barren some certain time; for in such as are lately delivered, you can see nothing but a cavity and no straitness at all. This straitness we call the proper orifice of the wombe, which is most exactly shut after conception, especially untill the membrane, or coats encompassing the child be finished, and strong enough to contain the seed, that it flow not forth, nor be corrupted by entrance of the air; for it is opened to send forth the seed, and in some the courses and serous humors, which are heaped up in the wombe in the time of their being with child.

From this orifice the neck of the wombe taking its originall, is extended even to the privities. It is of a musculous substance, composed of soft flesh, because it might be extended and contracted, wrinkled, and stretched forth, and unfolded, and wrested, and shaken at the coming forth of the child, and after be restored to its former soundness and integrity. In process of age it grows harder, both by use of venery, and also by reason of age, by which the whole body in all parts thereof becomes dry and hard. But in growing, and in young women, it is more tractable and flexible for the necessity of nature.

Its magnitude. Composition.

The magnitude is sufficiently large in all dimensions, though divers, by reason of the infinite variety of bodies. The figure is long, round, and hollow. The composition is the same with the wombe, but it receives not so many vessels as the wombe; for it hath none but those which are sent from the *Hypogastrick* veins, by the branches ascending to the wombe. This neck on the inside is wrinkled with many crests, like the upper part of a dogs mouth, so in copulation to cause greater pleasure by that inequality, and also to shorten the act.

Number and site.

It is only one, and that situate between the neck of the bladder and the right gut, to which it closely sticketh, as to the wombe by the proper orifice thereof, and to the privities by its own orifice; but by the vessels to all the parts from whence they are sent.

Temper.

It is of a cold and dry temper, and the way to admit the seed into the wombe, to exclude the infant out of the wombe, as also the menstruall evacuation. But it is worth obser-

vation,

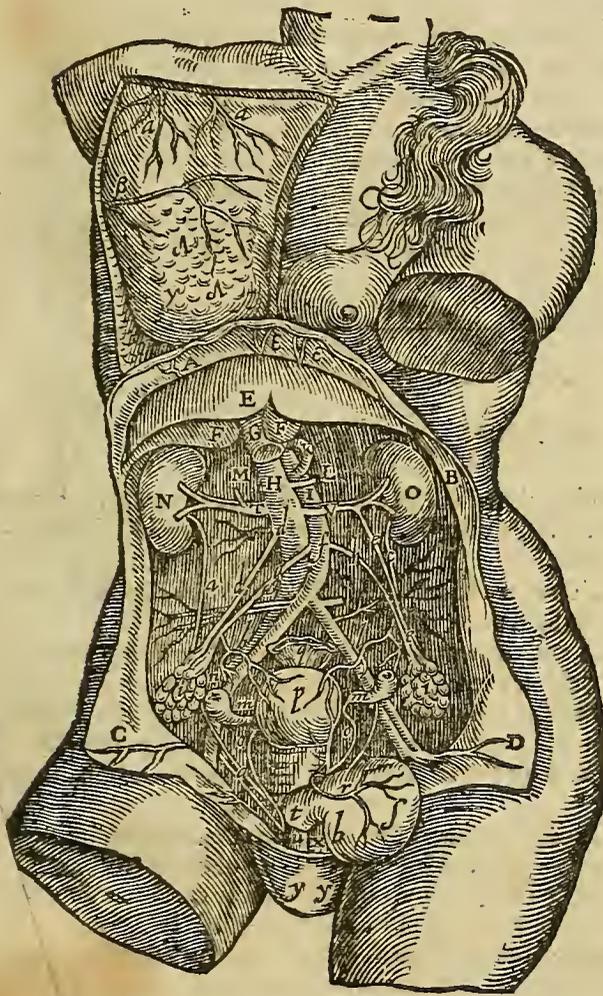

vation, that in all this passage there is no such membrane found, as that they called *Hymen*, which they feigned to be broken at the first coition. Yet notwithstanding *Columbus*, *Fallopianus*, *Wierus*, and many other learned men of our time think otherwise, and say, that in Virgins a little above the passage of the urine, may be found and seen such a nervous membrane, placed overthwart as it were in the middle way of this neck, and perforated for the passages of the courses. But you may find this false by experience; it is likely the ancients fell into this error through this occasion, because that in some a good quantity of blood breaks forth of these places at the first copulation.

But it is more probable, that this happens by the violent attrition of certain vessels lying in the inward superficies of the neck of the wombe, not being able to endure without breaking so great extension as that nervous neck undergoes at the first coition. For a maid which is marriageable, and hath her genitall parts proportionable in quantity and bigness to a mans; shall find no such effusion of blood, as we shall shew more at large in our Book of Generation.

No Hymen.

The Figures belonging to the Dugs and Breasts.

aa. The veins of the Dugs which come from those, which descending from the top of the shoulder, are refered to the skin. b. the veins of the dugs derived from those which through the arm-hole are led into the hand. c. the body of the Dug or Breast. dd. the kernels and fat between the breasts. ee. the vessels of the dugs descending from the lower part of the neck called *jugulum*, unto the breast bone.

This neck ends at the privities, where its proper orifice is, which privy parts we must treat of, as being the productions and *appendices* of this neck. This *Pudendum*, or privy, is of a middle substance, between the flesh and a nerve; the magnitude is sufficiently large, the figure, round, hollow, long. It is composed of veins, arteries, nerves, descending to the neck of the wombe, and a double coat proceeding from the true skin and fleshy pannicle; both these coats are firmly united by the flesh coming between them; whereupon it is said, that this part consists of a musculous coat. It is one in number, situate above the *Peritonæum*. It hath connexion with the fundament, the neck of the wombe and bladder by both their peculiar orifices.

It hath a middle temper, between hot, and cold, moist and dry. It hath the same use as a mans *Præputium* or fore-skin, that is, that together with the *Nymphae* it may hinder the entrance of the air, by which the wombe may be in danger to take cold. The lips of the privities called by the Greeks *πίρρυσία*, by the Latines *Ale*, contain all that region which is invested with hairs; and because we have said into mention of these *Nymphae*, you must know that they are as it were productions of the musculous skin, which descend on both sides, from the upper part of the share-bone downwards; even to the orifice of the neck of the bladder, oft times growing to so great a bigness, that they will stand out like a mans yard. Wherefore in some they must be cut off in their young years, yet with a great deal of caution, lest if they be cut too rashly, so great an effusion of blood may follow, that it may cause, either death to the woman, or barreness of the wombe by reason of the refrigeration by the too great effusion of blood. The latter Anatomists, as *Columbus* and *Fallopianus*, besides these parts, have made mention of another particle, which stands forth in the upper part of the privities, and also of the urinary passage, which joyns together those wings we formerly mentioned. *Columbus* calls it *Tentigo*, *Fallopianus*, *Cleitoris*, whence proceeds that infamous word *Cleitorizein*, (which signifies impudently to handle that part.) But because it is an obscene part, let those which desire to know more of it, read the Authors which I cited.

C H A P. XXXV.

Of the Coats containing the Infant in the wombe, and of the Navell.

THe membranes or coats containing the Infant in the wombe of the mother, are of a spermatick and nervous substance, having their matter from the seed of the mother. But they are nervous that so they may be the more easily extended, as it shall be necessary for the child. They are of good length and breadth, especially near the time of deliverance, they are round in figure like the wombe.

Their composition is of veins, arteries, and their proper substance. The veins, and arteries, are distributed to them (whether obscurely or manifestly, more or fewer) from the wombe by the *Cotyledones*, which have the same office, as long as the child is contained in the wombe, as the nipples or paps of the nurses after it is born. For thus the wombe brings the *Cotyledones*, or veins, degenerating into them through the coats like certain paps to the infant shut up in them.

These coats are three in number according to *Galen*; one called the *Chorion*, Secundine, after birth; the other *Allantoides*; the third *Amnios*. I find this number of coats in beasts, but not in women, unless peradventure any will reckon up in the number of the coats, the *Cotyledones* swollen up, and grown into a fleshy mass, which many skilfull in Anatomy do write, which opinion notwithstanding we cannot receive as true. I could never in any I see find the *Allantoides* in women with child, neither in the infant born in the sixth, seventh, eighth, or in the full time, being the ninth month, although I have sought it with all possible diligence, the Midwives being set apart, which might have violated some of the coats.

But thus I went about this business, I divided the dead body of the mother crosswise upon the region of the wombe, and taking away all impediments which might either hinder, or obscure our diligence, with as much dexterity as was possible, we did not only draw away that receptacle or den of the Infant, from the inward surface of the wombe, which it stuck by the *Cotyledones*, but we also took away the first membrane which we call *Chorion*, from that which lies next under it, called *Amnios*, without any rending or tearing for thus we poured forth no moisture, whereby it might be said, that any coat made for the containing of that humor, was rent or torn. And then we diligently looked, having many witnesses and spectators present, if in any place there did appear any distinction of these three membranes, the *Allantoides* and *Amnios*, for the separating the contained humors, and for other uses which they mention.

But when we could perceive no such thing, we took the *Amnios* filled with moisture on the upper side, and having opened it, two servants so holding the partition, that no moisture might flow out of it into the circumference of the *Chorion* or wombe, then presently

Ale.
πίρρυσία.

Cleitoris, tentigo.

Their substance, magnitude, figure, and composition.

The number.

with sponges we drew out by little and little all the humidity contained in it, the infant yet contained in it, which was fit to come forth, that so the coat *Amnios* being freed of this moisture, we might see whether there were any other humor contained in any other coat besides. But having done this with singular diligence and fidelity, we could see no other humor, nor no other separation of the membranes besides.

So that, from that time I have confidently held this opinion, that the infant in the womb, is only wrapped in two coats, the *Chorion* and *Amnios*. But yet not satisfied by this experience, that I might yet be more certain concerning this *Allantoides*, having passed through the two former coats, I came to the infant, and I put a quill into its bladder, and blew it up as forcibly as I could, so to try, if by that blowing I might force the air into that coat which we questioned, as some have written. But neither thus could I drive any air from hence, through the navell into the controverted coat, but rather I found it to fly out of the bladder by the privities. Wherefore I am certainly persuaded that there is no *Allantoides*. Moreover I could never finde nor see in the navell that passage called the *Urachus*, which they affirm to be the beginning and originall of the coat *Allantoides*. But if it be ganted, that there is no such coat as the *Allantoides*, what discommodity wil arise hereof? specially seeing the sweat and urine of the infant may easily, and without any discommodity be received, collected, and contained in the same coat, by reason of the small difference which is between them. But if any object, That the urine by its sharpness and touching will hurt the infant: I will answer, there can be no so great sharpness in the urine of so small an infant; and that, if that there be any, it is tempered by the admixture of the gentle vapr of sweat.

Besides, if you consider, or have regard to the use of such an humor (which is to hold up the child, lest by its weight it break the ties, by which it is bound to the womb;) we shall finde no humor more fit for this purpose than this serous, as which by its thickness is much more fit to bear up a weight, than the thin and too liquid sweat. For so we see the sea or salt-water carries greater weights without danger of drowning than fresh rivers do. Wherefore I conclude that there is no need, that the urine should be kept and contained in one coat, and the sweat in another. The Ancients who have writ otherwise, have written from observations made in beasts. Wherefore we make but only two coats, the *Chorion* and *Amnios*; the one of which, seeing it contains the other, they both so encompass the child, that they vest it on every side.

Felopijs in some sort seems to be of this opinion; for he only makes two coats, the *Chorion* and *Amnios*; but he thinks the infant makes the water into a certain part of the *Chorion*, as you may perceive by reading of his Observations. Both these coats are tyed between themselves by the intercourse of most slender nervous fibers, and small vessels penetrating from the outer *Chorion* to the inner *Amnios*. Wherefore unless you varily handle these coats, you may easily tear the *Amnios* in separating it. They are of the same temper with other membranes. Their use is different, for the *Chorion* is made both for the preservation of the vessels, which it receives from the womb for the generating of the umbilicall veins and arteries, as also to keep whole and safe the parts which it invests.

But the *Amnios* is to receive and contain the excrementitious and serous humors, which the child shut up in the womb is accustomed to evacuate. But this coat is very thin and soft, but strong and smooth, lest by its touch it might hurt the infant, whereupon it is called the Lambskin-coat.

C H A P. XXXVI.

Of the Navell.

The Navell follows these coats; It is a white body, somewhat resembling the wreathen cord, or girdle of the Franciscan-friers, but that it hath not the knots standing so far out, but only swelling in certain places, resembling a knot, only lifted up on one side; it arises and takes its originall from a fleshy mass, which we expressed by the name of swelling *Cotyledones*, and goes into the midst of the lower belly of the infant, yea verily into the midst of the whole body, whose root it is therefore said to be. For even as a tree by the root sucks nourishment from the earth, so the infant in the womb draws its nourishment by the navell. The greatness of it in breadth and thickness, equals the bigness of the little finger. But it is a foot and a half long, so that children are brought forth with it, encompassing their middle, neck, arms, or legs. The figure of it is round. It is composed of two arteries, one vein, and two coats. It hath these vessels from that great multitude of capillary veins and arteries, which are seen dispersed over the *Chorion*. Wherefore the vein entering in at the Navell, penetrates from thence into the hollow part of the Liver, where divided into two, according to *Galens* opinion, it makes the gate and hollow veins. But the arteries, carried

He shews by three severall reasons that there is no *Allantoides*.

Their temper and use.

What the Navell is.

The Navell is the center of the body.

Lib de format. fetus in utero.

by

by themselves the length of the Navell, cast themselves into the *Iliacæ*, which they make, as also all other, that from thence the vitall spirit may be carried by them over all the infant. It hath its two coats from the *Chorion*.

There is only one Vein in a child's Navell, but no *Ura-chus*.

But seeing they are mutually woven and conjoined without any *medium*, and are of a sufficient strength and thickness over all the Navell, they may seem to make the infants external skin and fleshy Pannicle. I know very many reckon two Umbilicall veins, as also arteries, and the *Urachus*, by, or through which the urine flows into the coat *Allantoides*. But because this is not to be found in women, but only in beasts, I willingly omit it, because I do not intend to mention any parts, but such as belong to humane bodies. Yet if there be any, which can teach me, that these parts, which I think proper to brute beasts, are to be found in women, I willingly confess, and that to his credit, from whom I have raped such benefit.

The other things that may be required concerning the Navell, as of its number, site, connexion, temper and use, may easily appear by that we have spoken before. For we have apparently set down the use, when we said, the Navell was made for that purpose, that the infant may be nourished by it, as the tree by the root, by reason of the continuation of the vessels thereof, with the preparing spermatick vessels made by God for that purpose, to whom be honor and glory for ever and ever. *Amen*.

The End of the third Book

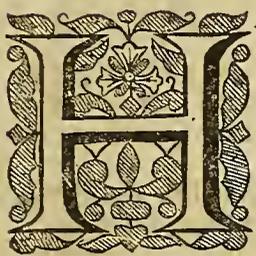

The Fourth Book,

Treating of the Vitall parts contained in the

CHEST.

The PREFACE.

AVING finished the first Book of our Anatomy, in explanation of the naturall parts contained in the lower belly, now order requires, that we treat of the Brest; that so the parts in some sort already explained (I mean the veins and arteries) may be dispatched after the same order and manner, without interposition of any other matter.

And besides also that we may the more exactly and chearfully shew the rest of the parts which remain, as the head and limbs, knowing already the originall of those vessels which are dispersed through them. To this purpose, we will define what the Chest is, and then we will divide it into its parts. Thirdly, in these we will consider which parts contain, and which are contained, that so we may more happily finish our intended discourse.

CHAP. I.

What the Thorax or the Chest is; into what parts it may be divided, and the nature of these parts.

HE *Thorax*, or Chest, is the middle belly, terminated or bounded above with the coller-bones, below with the Midriff, before with the *Sternum* or brest, behinde, with the twelve *Vertebra's* of the back on both sides, with the true and bastard ribs, and with the intercostall and intercartilagineous muscles. Nature hath given it this structure and composition, lest that being a defence for the vitall parts against externall injuries, it should hinder respiration; which is no less needfull for the preservation of the native heat diffused by the vital spirits, and shut up in the heart, as in the fountain thereof, against internall injuries, than the other fore-mentioned parts against externall. For if the Chest should have been all bony, verily it had been the stronger, but it would have hindred our respiration or breathing, which is performed by the dilating and contracting thereof. Wherefore lest one of these should hinder the other, Nature hath framed it, partly bony and grilly, and partly fleshy. Some render another reason hereof, which is, that Nature hath framed the chest, that it might here also observe the order used by it in the fabrick of things, which is, that it might conjoin the parts much disagreeing in their composure, as the lower belly, altogether fleshy, and the head all bony, by a medium partaker both of the bony and fleshy substance; which course we see it hath observed in the connexion of the fire and water, by the interposition of the air; of the earth and air, by the water placed between them.

The Chest is divided into three parts, the upper, lower, and middle; the coller-bones contain the upper; the Midriff the lower; and the *Sternum* the middle. The *Sternum* in *Galens* opinion is composed of seven bones, I beleve by reason of the great stature of the people that lived then. Now in our times, you shall oft find it compact of three, four, or five bones, although we wil not deny, but that we have often observed it (especially in young bodies) to consist of seven or eight bones.

Wherefore those who have fewer bones in number in their *Sternum*, have them larger, that they might be sufficient to receive the ribs. This is the common opinion of the *Sternum*. Yet *Fallopins* hath described it far otherwise; wherefore let those who desire to know more hereof, look in his observations.

At the lower part of the *Sternum*, there is a gristle, called commonly *Furcula*, and *Malum granatum*, or the Pomgranate, because it resembles that fruit; others call it *Cartilago scuti-formis*, that is, the brest-blade.

The containing parts of the Chest.

Why nature hath made the Chest partly bony, partly grilly.

The number of the bones of the Sternum.

Cartilago scuti-formis, the brest-blade.

It is placed there, to be (as it were) a bulwark or defence to the mouth of the stomach, endued with most exquisit sense; and also that it should do the like to that part of the Midriff which the Liver bears up in that place, situate above the orifice of the ventricle by the ligament coming between, descending from the lower part of the same grisle into the upper part of the Liver.

The common people think that this grisle sometimes falls down. But it so adheres, and is united to the bones of the *Sternon*, that the falling thereof may seem to be without any danger, although oft-times it may be so moistened with watery and ferous humidities, with which the orifice of the stomach abounds, that (as it were) soaked and drunk with these, it may be so relaxed, that it may seem to be out of its place; in which case it may be pressed and forced by the hand into the former place and seat, as also by applying outwardly, and taking inwardly astringent and drying medicines to exhaust the superfluous humidity.

This Grisle at its beginning is narrow, but more broad and obtuse at its end, somewhat resembling the round or blunt point of a sword, whereupon it is also called *Cartilago Eniformis*, or the sword-like grisle. In some it hath a double, in others a single point.

In old people, it degenerates into a bone. Now because we make mention of this grisle, we will shew both what a Grisle is, and how many differences thereof there be, that henceforward as often as we shall have occasion to speak of a grisle, you may understand what it is.

What a Grisle is.

A Grisle is a similar part of our bodies, next to a bone most terrestriall, cold, dry, hard, weighty, and without sense, differing from a bone in driness only, the which is more in a bone. Wherefore a Grisle being lost, cannot be regenerated, like as a bone, without the interposition of a *Callus*.

The differences thereof.

The differences of these are almost the same with bones, that is, from their consistence, substance, greatness, number, site, figure, connexion, action, and use. Omitting the other for brevity sake, I will only handle those differences which arise from site, use and connexion. Therefore gristles, either adhere to the bones, or of, and by themselves make some part, as the gristles of the ey-lids called *Tarsi*, of the *Epiglottis* and throtle. And others which adhere to bones, either adhere by the interposition of no medium, as those which come between the bones of the *Sternon*, the collar-bones, the share and haunch-bones, and others; or by a ligament coming between, as those which are at the ends of the bastard-ribs to the *Sternon* by the means of a ligament, that by those ligaments being softer than a grisle, the motions of the Chest may be more quickly and safely performed. The gristles which depend on bones, do not only yeeld strength to the bones, but to themselves, and the parts contained in them, against such things as may break and bruise them. The gristles of the *Sternon*, and at the ends of the bastard-ribs are of this sort.

Their twofold use.

By this we may gather, that the gristles have a double use, one to polish and levigate the parts to which that slippery smoothness was necessary for performance of their duty; and for this use serve the gristles which are at the joints, to make their motions the more nimble. The other use is to defend those parts upon which they are placed, from externall injuries, by breaking violent assaults, by somewhat yeelding to their impression, no otherwise than soft things opposed against cannon-shot. We will prosecute the other differences of gristles in their place, as occasion shall be offered and required.

CHAP. II.

Of the containing and contained parts of the Chest.

The division of the Chest into its parts.

The containing parts of the Chest are both the skins, the fleshy Pannicle, the fat, the breasts, the common coat of the Muscles, the muscles of that place, the fore-mentioned bones, the coat investing the ribs, and the *Diaphragma* or Midriff. The parts contained are the *Mediastinum*, the *pericardium* or purse of the heart, the heart, the lungs and their vessels. Of the containing parts, some are common to all the body, or the most part thereof, as both the skins, the fleshy pannicle and fat. Of which being we have spoken in our first Book, there is no need now further to insist upon: Others are proper to the Chest, as its muscles, of which we will speak in their place, the breasts, the forementioned bones, the membrane investing the ribs, and the *Diaphragma* or Midriff.

We will treat of all these in order, after we have first shewed you the way, how you may separate the skin from the rest of the Chest. Putting your knife down even to the perfect division of the skin, you must draw a straight line from the upper part of the lower belly, even to the chin; then draw another straight line, overthwart at the collar-bones even to the shoulder-blades; and in the places beneath the collar-bones: (if you desire to shun prolixity) you may at once separate both the skins, the fleshy Pannicle, the fat, and common coat of the muscles; because these parts were shewed and spoken of in the dissection of the lower belly.

Yet

Yet you must reserve the breasts in dissecting of the bodies of women; wherefore from the upper parts of the breasts, as artificially as you can, separate only the skin from the parts lying under it, that so you may shew the Pannicle which there becometh fleshy and musculous, and is so spread over the neck and parts of the face, even to the roots of the hairs.

CHAP. III.

Of the Breasts or Dugs.

The Breasts, as we said, when we spoke of the nature of Glandules, are of a glandulous substance, white, rare, or spongiouse; in maids and women that do not give suck, they are more solid and not so large.

Wherefore the bigness of the Dugs is different, although of a sufficient magnitude in all. Their figure is round, somewhat long, and in some sort Pyramidall. Their compofure is of the skin, the fleshy pannicle, glandules, fat, nerves, veins, and arteries, descending to them from the *Axillaris* under the *Sternon*, betwixt the fourth and fifth, and sometimes the sixth of the true ribs.

And there they are divided into infinite rivelets by the interposition of the glandules and fat, by which fit matter may be brought, to be changed into milk by the faculty of the dugs.

We will speak no more of the nature of glandules or kernels, as having treated of them before; only we will add this, that some of the glandules have nerves, as those of the Breasts, which they receive from the parts lying under them, that is, from the intercostall, by which it comes to pass, that they have most exquisit sense. Others want a nerve, as those which serve only for division of the vessels, and which have no action, but only use.

They be two in number, on each side one, seated at the sides of the *Sternon* upon the fourth, fifth and sixth true ribs.

Wherefore they have connexion with the mentioned parts with their body, but by their vessels with all other parts, but especially with the womb by the reliques of the mamillary veins and arteries, which descend down at the sides of the brest-blade; in which place these veins insinuating themselves through the substance of the muscles; are a little above the navell conjoined with the *Epigastricks*, whose originall is in some sort opposite to the *Hypogastricks*, which send forth branches to the womb. By the meeting of these it is more likely that this commerce should arise, than from other and those almost capillary branches, which are sometimes seen to descend to the womb from the *Epigastrick*.

They are of a cold and moist temper, wherefore they say that the blood by being converted into milk * becomes raw, flegmatick and white by the force of the proper flesh of the dugs. Their action is to prepare nourishment for the new-born babe, to warm the heart from whence they have received heat, and to adorn the brest.

By this you may know that some Glandules have action, others use, and some both. At the top of the dugs there are certain hillocks, or eminencies called teats or nipples, by sucking of which the childe is nourished through certain small and crooked passages, which though they appear manifest to the sight, whilst you press out the milk by pressing the dug, yet when the milk is pressed out, they do not appear, nor so much as admit the point of a needle, by reason of the crooked ways made by nature in those passages, for this use, that the milk being perfectly made, should not flow out of its own accord against the nurses will. For so the seed is retained and kept for a certain time in the Prostats.

CHAP. IIII.

Of the Clavicles, or Coller-bones and Ribs.

If we should handle these parts after the common order, we should now treat of the Muscles of the Chest which move the arm, and serve for respiration, and which first offer themselves to our sight.

But for that they cannot be fitly shewed, unless we hurt the muscles of the shoulder-lade and neck, therefore I think it better to defer the explanation of these Muscles, untill such time as I have shewed the rest of the contained and containing parts, not only of the Chest, but also of the Head, that having finished these, we may come to a full demonstration of all the rest of the muscles, beginning with those of the head, which we first meet with, and so prosecuting the rest even to the muscles of the feet, as they shall seem to offer themselves more fitly to dissection, that so, as much as lyes in us, we may shun confusion.

Wherefore to return to our proposed task; after the foresaid muscles come the Coller-bones, the *Sternon*, and Ribs.

Their substance.

Magnitude
Figure.
Composure.

Which Glandules have nerves, and which have none.

Their connexion.

How the breasts and womb communicate each with other.

Their temper.
* *Recrudescere*
Their action and use.

The Nipples;

But that these parts may be the more easily understood, we must first know what a bone is, and whence the differences thereof are drawn.

What a Bone is.

Therefore a Bone is a part of our body most terrestriall, cold, dry, hard, wanting all manifest sense, if the teeth be excepted.

A double sense

I said manifest sense, that you may understand that the parts have a double sense of touching, the one manifest, such as resides in the flesh, skin, membranes, nerves, teeth, and certain other parts; the other obscure, yet which may suffice to discern the helping and hurting tactile qualities, such sense the bowels and bones have; for very small fibers of the nerves are disseminated to these parts by mediation of their coat, or membrane, I say, so small, that they can scarce be discerned by the eyes, unless (as *Galen* saith) by plucking such coats away from the parts.

Lib. 1. de Locis affe&is.

Why the bones have such smal veins.

But it is no marvail if Nature would have these parts in like manner to have such small veins, contrary to the lungs and most part of the muscles, only to yeeld so much nourishment to the part, as should be needfull; for seeing the substance of the bones is cold, hard, dense and solid, it wastes the less.

Whence the difference of bones may be taken.

Wherefore they need not so much blood for their nourishment, as the hot and soft parts; and besides the lesser bones have neither veins nor arteries, but draw fit nourishment, only by the force of the attractive faculty implanted in them.

The Clavicles or coller-bone.

The differences of bones are taken from many things, as from their *Apophyses*, *Epiphyses*, gristles, necks, heads, solidity, cavity, eminencies, marrow, consistence, bigness, number, figure, site. We will prosecute all these as they shall offer themselves in the demonstration of the bones; to which doctrine we will give a beginning at the Clavicles or coller-bones.

The Clavicles are two very hard and solid bones, without any great or notable cavity, situate on each side betwixt the side and upper part of the *Sternon* and top of the shoulder-blade, for the strength and stability of these parts, whence they take the name of *Claviculae* Clavicles, (from the Greek *κλει*, which signifies, a Key or any other Bar or fastning of a door.) They carry the shape of a Surgeons Levatory.

Lib. 13. de usu part. cap. 11.

But you must note that the Clavicles seem to be fastned to the *Sternon* by the mediation of a gristly bone. Moreover the space and cavity contained within the coller-bones is called by the Latins *jugulum*, by the French the upper *furcula*, because the jugular veins pass that way; it sticks to the upper process of the shoulder by a Gristle which *Galen* calls the small gristle bone, although it be nothing else but a production of the *Os juguli*.

For the *Sternon*, which we said is framed of divers bones, as sometimes 3, sometimes 4, 5, 6, 7, and sometimes 8, you must note they are very spongy and full of pores, and of a far softer consistence than the coller-bones, wherefore more subject to corruption; besides they are mutually joined by interposition of muscles. Their use is to be as a shield to defend the vitall parts.

The Ribs.

The Ribs are 24 in number, on each side 12. seven of these are called true or perfect ribs, because they make a circle, at the one end joined to the *Sternon*, on the other to the *vertebra's*; the other are called bastard or short ribs, because they fall short in their way and come not to the *Sternon*; but they are fastned on the fore-side to the *Sternon* by gristles and ligaments, but on the back-part to the transverse *vertebra's* of the back-bone, and to the sides of the said *vertebra's*. But the short ribs are only knit to the *vertebra's*, wherefore that part of the *vertebra's* is called the root of the ribs.

Their consistence.

The exterior or fore-part of the bastard or short ribs is gristly, that they should not be broken, and that they might be the easier lifted up in the distensions of the stomach filled with meat. They are of a consistence sufficiently hard, yet more towards their root, than at the *Sternon*, where they come nearer together, and are more hardly broken; they are smooth both within and without, but in the midst they have some sign of being double; or hollow to receive the veins and arteries, which nourish their bony substance; they are fashioned like a bow; their use is the same with the *Sternon*, and besides to carry and strengthen the muscles serving for respiration.

CHAP. V.

The Anatomical administration of the Sternon.

He coat investing the ribs, which the common Anatomists call *Pleura*, is the last of the containing parts of the Chest, which because it lyes hid in the inner part thereof, it cannot be shown unless by pulling asunder of the *Sternon*; wherefore we must now shew the manner of opening the *Sternon*, that hereby we may not violate the originall or insertion of any of the muscles. Wherefore first you must understand that he which will shew in their proper place their originall and insertion of the pectorall muscles, of the *Mastoides*, of the two muscles of the bone *Hyois*, of the muscles *subclavii*, and *intercartilaginei*, ought first of all to separate all the pectorall muscles from

the *Sternon* and the gristles from the true ribs; then to cut the ligaments, next the bones themselves, even from the sixth true rib to the clavicles.

And then shewing the *Mediastinum* stretched under the *Sternon* all the length thereof, he must separate the *Sternon* with his knife, and bend it up to the clavicles, and there cut it, reserving together with it the four muscles, that is, the two *Mastoides*, and the two moving the bone *Hyois*, because they either wholly or for the most part arise from the *sternon*.

Lastly, the Clavicles being somewhat thrust upwards, the gristles must on each side be turned outwards towards the arm; that so the containing parts of the Chest may not only lye open to view, and be easily shewed, but also the muscles may be contained in their place, untill they come to be shewed in their order.

And because the collar-bones must be lifted up very high, that the recurrent nerves may be more easily seen, and the distribution of the veins and arteries, the two small subclavian muscles, one on each side must be shown by the way, who have their originall from the inner and fore-part of the Clavicles, and an oblique descent to the *Sternon* towards the gristle of the first rib.

For the Clavicles cannot be thus separated, but that these muscles must be violated and spoiled. Also you may divide the *Sternon* in the midst, that you may shew the inward pectoral muscles whole, having separated the muscles which arise from the upper part. All which things being performed as they ought, we must come to the coat investing the ribs, and then to the *Mediastinum*, as arising from it.

CHAP. VI.

Of the Pleura, or coat investing the Ribs.

The *Tunica subcostalis*, or coat investing the Ribs, being the last of the containing parts of the Chest, is a large and a broad membrane answerable in proportion of use and action to the *Peritonæum* of the lower belly. For as the *Peritonæum* generally and particularly covers all the naturall parts, binding and holding them in their places, so this coat invests all the vitall parts in generall, because it is stretched over all the inside of the Chest, but in particular whilst it gives each a coat from it self.

What the membrane investing the ribs is.

It hath its original from the *periosteum* (or as others will have it, from the *pericranium*) investing the *vertebra's* of the Chest at the roots of the ribs. Wherefore it sticks very fast to the ribs, scarce to be separated, as also to all the parts bounding the Chest, and contained in it.

Its original.

Vesalius reprehends *Galen*, because he said, that this was double on both sides; yet *Columbus* defends *Galen*, and verily it is seen to be double in the inner part of the Chest, under the ribs and the muscles of the ribs, that in that space there may be way for the veins, arteries, and nerves.

Some have made it twofold, and divided it into the internal and external; as those which have made two sorts of *Plurifies*, the true and bastard; placing the external above the Ribs and intercostal muscles; but the internal under the ribs, muscles, *Diaphragma* and *Sternon*.

Whether, as there is a two-fold *Plurifie*, so also a double *Pleura*.

But we, to shun ambiguity, intend only to prosecute those things which are manifest to the eyes; wherefore we say, that the ribs are lined on the inside with a double coat; on which immediatly and firmly sticks to them on every side called the *periosteum*, which is common to them and other bones.

The other which lyes upon that *periosteum*, and on the inside invests all the Ribs, whence it is called the *subcostalis tunica*. The substance, temper and compofure are the same, as in other membranes. The magnitude in length, as also the figure, is the same with the compass of the inner part of the Chest; the thickness of it is very little. This coat is commonly called the *Pleura*, from the name of the part which it covers or lines, (for the Greeks call the ribs *πλευρα*) and in like manner which happens betwixt the *periosteum* and this *pleura*, is called either a true or bastard *Plurifie*.

The magnitude and figure.

CHAP. VII.

Of the Mediastinum.

Now we must speak of the parts contained in the Chest, seeing we have already handled the containing, beginning with the *Mediastinum* as being a part which in dissection first presents it self to our sight. The *Mediastinum* is of the same substance, thickness, compofure, number, temper, as the *Pleura*. For the substance of the *Mediastinum* is membranous, and though it be stretched al the length of the Chest, yet it is of a smal thickness, receiving veins, nerves and arteries from al the parts to which it is knit, like as the *pleura* doth; but especially from the mamillary vessels, descending under the *sternon*.

The substance and magnitude.

It is in number one, but it is made of two membranes produced from the subcostall, for this ascending on each side by the hollownes of the Chest to the *sternon*, and then at right angles it is reflected to the bodies of the *vertebra's*, whence the *pleura* hath its originall.

In that reflection there is so much distance between each membrane, as may be sufficient to receive two fingers. For otherwise, seeing that they cannot penetrate through the heart, it was fit each side of the *Pleura* should turn to the *Pericardium*, that so they might arrive at the appointed place without offence. Neither yet is that space void and empty, but woven with many small nervous fibers. *Columbus* adds, that that place is often filled with a certain humor besides nature, which you may draw out or evacuate by opening the *sternon*.

The figure.

Yet I would gladly learn of *Columbus*, by what signs we may know that such an humor is contained there. For the figure, the *Mediastinum* with the *Pleura* on each side, represents the figure of a leather bottle, whose flat side is the *Mediastinum*, whose other side the *Pleura*; the bottom that part of the *Pleura* which is next the Midriff; the mouth the upper part of the *Pleura* at the first ribs. We shewed the site and connexion of the *Mediastinum*, when we declared its originall.

The use.

The use thereof is to separate the vitall parts (as it were) into two cells, the right and left, that if peradventure it happen that the one be hurt, the creature may live by the benefit of the other.

And it hath another use, which is to prop and hold up the *Pericardium*, that it fall not upon the heart with its weight, but tossed with the motions of the heart and Chest, it may move to this or that side.

CHAP. VIII.

Of the Diaphragma or Midriff.

What the Midriff is.

Although the Midriff may seem to be accounted rather a part containing than contained, yet for commodities sake we have deferred the demonstration thereof till now. Therefore it is a muscle round and long, terminating the lower part of the Chest.

Its substance, composition, &c.

It is of the same substance, composition and temper, as the muscles of the *Epigastrium*; it is made of two coats, the lower whereof is from the *Peritonæum*, and the upper from the *Pleura*. Which getting to them flesh, but not there, but in their circumference, by the benefit of the blood brought thither by the veins and arteries distributed through it, turn into a muscle, whose middle is nervous and membranous, but the extremities by which it is inserted, one while fleshy, as in that part next to the bastard ribs; another while tendonous, as where it touches the first and second *vertebra's* of the loins, for it ends in them by two Tendons manifest enough. It is one in number, interposed with an oblique site betwixt the naturall and vitall parts. It hath connexion with the lower part of the *Sternon* and short ribs, and the two first *vertebra's* of the loins, but by its coats and vessels with the parts from whence it received them.

Connexion.

Quantity.

The extent thereof is equal to the compass of the lower part of the Chest. The length of it is from the breast-blade, even to the first and second *vertebra* of the loins. The thickness is diverse, for it is far thicker in its fleshy extremity, than in its nervous originall.

Action.

The Action thereof is to help the expulsion of the Excrements by the mutuall assistance of the *Epigastrick* muscles, but the chief use is for respiration, of which it is one of the prime instruments. This partition the Ancients called *Phrenes*, because the inflammation thereof caused like symptomes as the inflammation of the brain, by reason of the large nerves on each side one, which come to it directly and primarily from the third, fourth, and fifth *vertebra* of the neck. This muscle differs from other muscles, specially in figure. It is perforated in three places, to give way or passage to the ascendent Hollow-vein, to the artery *Aorta*, and the Gullet.

Why the Diaphragma was called Phrenes.

CHAP. IX.

Of the Lungs.

Their substance. Quantity. The Lobes thereof.

The Lungs are of a soft substance and flesh, rare and like a sponge, of a various colour pamed; their quantity is sufficiently large; for most commonly they are divided into four lobes disjoined with a manifest and visible division, on each side two, whereby they may be the more easily opened and contracted, and the air may the better enter.

Besides also in large bodies, who have a very great Chest, there is found a fifth lobe, arising from the second lobe of the right side, as a cushion or bolster to bear up the Hollow-vein ascending from the Midriff to the heart.

In little men who have a shorter Chest, because the heart is so near as to touch the *Diaphragma*, this lobe is not seen, yet it is always found in Dogs.

Figure.

The Lungs represent the figure or shape of an Oxes foot or hoof, for like it they are thicker

thicker in their basis, but slenderer in their circumference, as you may see in blowing them up, by the weazon, with your mouth or a pair of bellows. They are compounded of a coat coming from the *Pleura*, which on each side receives sufficient number of nerves from the sixth conjugation; and also of the *Vena arteriosa* coming from the right ventricle of the heart, and the *Arteria venosa* from the left, as shall be shewed in the Anatomy of the heart; besides the *Apera arteria* or weazon coming from the throat; and lastly its own flesh, which is nothing else than the concretion of cholerick blood poured out like foam about the divisions of the foresaid vessels, as we have said of other parts.

Composition.

The body of the Lungs is one in number, unless you will divide it into two, by reason of the variety of its site, because the Lobes of the Lungs stretched forth into the right and left side do almost involve all the heart, that so they may defend it against the hardness of the bones which are about it, they are tyed to the heart, chiefly at its basis, but to the roots of the ribs, and their *vertebra's* by the coat it hath from thence; but by the vessels to these parts from whence they proceed. But oft times presently from the first and naturall conformation they are bound to the circumference of the ribs by certain thin membranous productions which descend from thence to the Lungs, otherways they are tyed to the ribs by the *Pleura*.

The sticking of the lungs to the ribs.

The nourishment of the Lungs is unlike to the nourishment of other parts of the body; for you cannot finde a part equally rare, light, and full of rare, which may be nourished with blood equally thin and vaporous. In temper they incline more to heat than to cold whether you have regard to their compofure of cholerick blood, or their use, which is to prepare and alter the air, that it hurt not the heart by its coldness. The Lungs is the instrument of voice and breathing by the weazon or wind-pipe. For the Lobes are the instruments of voice, and the ligaments, of respiration. But the *Larinx* or Throtle is the chief instrument of the voice; for the Weazon first prepares the voice for the Throtle, in which it being in some measure formed, is perfected in the palat of the mouth, as in the upper part of a Lute, or such like instrument, by the help of the *Gargareon* or *uvula* as a certain quill to play withall.

Their nourishment.

But as long as one holds his breath, he cannot speak; for then the muscles of the *Larinx*; ribs, the *Diaphragma*, and the *Epi-gastrick* muscles are pressed down, whence proceeds a suppression of the vocall matter, which must be sent forth, in making or uttering a voice.

Nature would have the Lungs light for many reasons; the first is, That seeing they are of themselves immovable, they might be more obsequious and ready to follow the motion of the Chest; for when it is straitned, the Lungs are straitned and subside with it; and when it is dilated, they also are dilated, and swell so big that they almost fill up all the upper capacity thereof.

Why the lungs are light.

Another cause is, That by this their rarity they might more easily admit the entring air, at such times as they have much or sodain necessity, as in running a race.

And lastly, that in Plurisies and other purulent abscesses of the Chest, the *Pus* or matter poured forth into the capacity of the Chest, may be sucked in by the rare substance of the Lungs, and by that means the sooner sent forth and expectorated.

The use of respiration is to cool and temper the raging heat of the heart. For it is cooled in drawing in the breath by the cool air, and in sending out thereof by avoyding the hot fuliginous vapor. Therefore the Chest performs two contrary motions, for whilst it is dilated it draws in the encompassing air, and when it is depressed, it expels the fuliginous vapor of the heart; which any one may easily perceive by the example of a pair of Smiths bellows.

The use of respiration or breathing.

C H A P. X.

Of the Pericardium or Purse of the Heart.

The *Pericardium* is (as it were) the house of the Heart, which arising at the basis thereof (either the ligaments of the *vertebra's* situate there, or else the vessels of the heart yeelding it matter) is of a nervous, thick and dense substance without any fibers. It retains the figure of the Heart, and leaves an empty space for the heart to perform its proper motions. Wherefore the bigness of the *Pericardium* exceeds that of the heart.

Whence it hath its matter.

It consists of a double coat, one proper, of which we have spoken; another common, coming from the *Pleura*; and also of veins, arteries, and nerves; the vessels partly coming from the mamillary, partly from the *Diaphragma*, chiefly there where it touches it; the nerves come on each side from the sixth conjugation.

It is only one, placed about the heart, and annexed to it at the basis thereof by its membranes, to the originall of the Lungs, and the *vertebra's* lying under them, and by the vessels to the parts from whence it received them. It is of a cold and dry temper; as every membrane is.

Number and connexion.

The use thereof is to cover the heart, and preserve it in its native humidity, by a certain

Use,

naturall

naturall moisture contained in it, unless you had rather say that the moisture we see contained in the *Pericardium*, is generated in it after death by the condensation and concretion of the spirits. Although this seems not very likely, because it grows and is heaped up in so great quantity in living bodies, that it hinders the motion of the heart, and causes such palpitation or violent beating thereof, that it often suffocates a man.

From whence,
the matter of
the watery
humor contain-
ed in the
Pericardium.

The Consis-
tence.

For this Palpitation happens also to hearty and stout men, whose hearts are hot, but blood thin and waterish, by reason of some infirmity of the stomach or liver; and this humor may be generated of vapors which on every side exhale into the *Pericardium* from the blood boiling in the ventricles of the heart, where kept in by the density thereof, they turn into yellowish moisture, as we see it happens in an Alembick.

Nature would have the *Pericardium* of a dense and hard consistence, that by the force thereof the heart might be kept in better state; for if the *Pericardium* had bin bony, it would have made the heart like iron by the continuall attrition; on the contrary, if it had been soft and fungous, it would have made it spongy and soft like the lungs.

C H A P. XXX.

Of the Heart.

What the
heart is, and of
what substance

The Heart, the chief mansion of the Soul, the organ of the vitall faculty, the beginning of life, the fountain of the vitall spirits, and so consequently the continuall nourisher of the vitall heat, the first living and last dying; which because it must have a naturall motion of it self, was made of a dense, solid, and more compact substance than any other part of the body.

The three sorts
of fibers of the
heart.

The flesh thereof is woven with three sorts of fibers, for it hath the right in the inner part descending from the basis into the point, that they might dilate it, and so draw the blood from the Hollow vein into the receptacles thereof, and the breath or air from the lungs by the *Arteria venosa*; it hath the transverse without, which pass through the right at right angles, to contract the Heart, and so drive the vitall spirits into the great Artery *Aorta*, and the cholerick blood to the Lungs by the *Vena arteriosa* for their nourishment; It hath the oblique in the midst to contain the air and blood drawn thither by the forementioned vessels, untill they be sufficiently elaborate by the heart.

All these fibers do their parts by contracting themselves towards their originall, as the right from the point of the heart towards the basis, whereby it comes to pass that by this contraction of the fibers the heart dilated becomes shorter, but broader, no otherwise than it is made more long and narrow by the contraction of the transverse, but by the drawing of the oblique, it is lessened in that part which looks towards the *vertebra's*, which chiefly appears in the point thereof.

The magni-
tude.

It is of an indifferent bigness, but yet in some bigger, in some less, according to the diverse temper of cold or hot men, as we noted in the liver.

Figure.

The figure thereof is pyramidall, that is, it is broader in the basis, and narrower at his round point.

Composition.

It is composed of the most dense flesh of all the body, by the affusion of blood at the divisions and foldings of the vessels, and there concrete, as it happens also to the other entrails. For the blood being there a little more dried, than that which is concrete for the making of the Liver, turns into a fleshy substance more dense than the common flesh, even as in hollow ulcers, when they come to a cicatrize.

The proper
vessels.

It hath the Coronall veins and arteries, which it receives either on the right side from the Hollow vein, or on the left from the basis at the entrance of the artery *Aorta*. You cannot by your eye discern that the heart hath any other nerves than those which come to it with the *Pleura*.

The Nerves.

Yet I have plainly enough observed others in certain beasts which have great hearts, as swine; they appeared seated under the fat which covers the vessels and basis of the heart, lest the humid substance of these parts should be dissolved and dissipated by the burning heat of the heart. Whereby you may perceive that the heat of the heart is different from the Elementary heat, as that which suffers fat to grow about this entrail, where otherwise it doth not concrete unless by cold or a remiss heat, which thing is chiefly worth admiration.

Number and
sit.

The Heart is one alone, situate most commonly upon the fourth *vertebra* of the Chest, which is in the midst of the Chest. Yet some think that it inclines somewhat to the left side, because we there feel the motion or beating thereof; but that happens by reason of its left ventricle, which being it is filled with many spirits, and the beginning of the arteries, it beats far more vehemently, than the right. It required that seat by the decree of Nature; because that region is the most safe and armed, and besides it is here on every side covered (as it were) with the hands of the Lungs.

Connexion.

It hath connexion with the fore-mentioned *Vertebra's*, but by the parts composing it, with those parts from whence it hath them; with the Lungs by the *Vena arteriosa*,
and

and the *Arteria venosa*; and lastly, with all the parts of the body by the Arteries, which it sends to them all.

It is of a hot and moist temper, as every fleshy part is. The action thereof is, first to prepare the blood in its right ventricle, for the fit nourishment of the Lungs, for from hence it is that *Galen* saith, This right ventricle was made for the necessity of the Lungs. Secondly, to generate the vitall spirits in its left ventricle for the use of the whole body. But this spirit is nothing else than a certain middle substance between air and blood, fit to preserve and carry the native heat, wherefore it is named the Vitall, as being the author and preserver of life. In the inner parts of the heart there present themselves to our consideration the ventricles and the parts contained in the ventricles and between them; such are the *Valvule*, or valves, the vessels and their mouths, their distribution into the Lungs, the wall or partition, and the two productions or Ears of the heart; which because they are doubtful, whether they may be reckon'd amongst the externall or internall parts of the heart, I will here handle in the first place.

Therefore these *Auricule* or Ears are of a soft and nervous substance, compact of three sorts of fibers, that so by their softness they might the more easily follow the motions of the heart, and so break the violence of the matter entering the heart with great force when it is dilated. For otherwise by their violent and abundant entrance they might hurt the heart, and (as it were) overwhelm and suffocate it; but they have that capacity which we see given by nature, that so they might (as it were) keep in store the blood and air, and then by little and little draw it forth for the use or necessity of the heart. But if any enquire, if such matters may be drawn into the heart by the only force of the *Diastole*, *ad fugam vacui*, for avoyding of emptiness; I will answer, That that drawing in or attraction is caused by the heat of the heart, which continually draws these matters to it, no otherwise than a fire draws the adjacent air, and the flame of a candle the tallow which is about the weik for nourishments sake. Whilst the heart is dilated it draws the air, whilst it is drawn together or contracted it expels it. This motion of the heart is absolutely naturall, as the motion of the lungs is animall. Some add a third cause of the attraction of the heart, to wit, the similitude of the whole substance. But in my judgment, this rather takes place in that attraction which is of blood by the *venæ corales* for the proper nourishment of the heart, than in that which is performed for attraction of matters for the benefit of the whole body.

These Ears differ in quantity, for the right is far more capacious than the left, because it was made to receive a greater abundance of matter. They are two in number, on each side one, situate at the basis of the heart: The greater at the entrance of the hollow vein into the heart, the less at the entrance of the veinous and of the great Artery, with which parts they both have connexion. We have formerly declared what use they have, that is, to break the violence of the matters, and besides to be stays or props to the *Arteria venosa* and great Artery, which could not sustain so rapid and violent a motion as that of the Heart, by reason of their tenderness of substance.

Of the ventricles of the Heart.

THe Ventricles are in number two, on each side one, distinguished with a fleshy partition strong enough, having many holes in the superficies, yet no where piercing through.

The right of these Ventricles is the bigger, and encompassed with the softer and rarer flesh; the left is the lesser, but is engirt with a threefold more dense and compact flesh; for the right Ventricle was made for a place to receive the blood brought by the hollow vein, and for distributing of it, partly by the *Vena arteriosa* into the Lungs for their nourishment, partly into the left Ventricle, by sweating through the wall or partition, to yeeld matter for the generation of the vitall spirits.

Therefore because it was needfull there should be so great a quantity of this blood, it was likewise fit that there should be a place proportionable to receive that matter. And because the blood which was to be received in the right ventricle was more thick, it was not so needfull, that the flesh to contain it should be so compact; but on the contrary, the arterious blood and vital spirit have need of a more dense receptacle, for fear of wasting, and lest they should vanish into air; and also less room, that so the heat being united, might become the stronger, and more powerfully set upon the elaboration of the blood and spirits.

Therefore the right Ventricle of the heart is made for the preparation of the blood appointed for the nourishment of the Lungs, and the generation of the vitall spirits, as the Lungs are made for the mitigation or qualifying of the Air. Which works were necessary if the Physicall Axiome be true, *That like is nourished by like*, as the rare and spongy Lungs with more subtil blood; the substance of the heart gross and dense, with the veinous blood as it flows from the Liver, that is gross.

And it hath its Coronall veins from the Hollow vein, that it might thence draw as much as should be sufficient.

But the left Ventricle is for the perfecting of the vitall spirit, and the preservation of the native heat,

Temper and action.

What the vitall spirit is.

Their use.

The partition between the ventricles of the heart. Why the right ventricle is more capacious & less compact.

Why the right ventricle is more capacious & less compact.

The action of the right ventricle.

The action of the left ventricle.

Of the Orifices and Valves of the Heart.

The uses of the four orifices of the Heart.

Here be four Orifices of the heart, two in the right, and as many in the left ventricle; the greater of the two former gives passage to the vein, or the blood carried by the hollow vein to the heart; the lesser opens a passage to the *vena arteriosa*, or the cholerick blood carried in it for the nourishment of the lungs.

The larger of the two other makes a way for the distribution of the Artery *Aorta*, and the vitall spirit through all the body; but the lesser gives egress and regress to the *Arteria venosa*, or to the air and fuliginous vapors. And because it was convenient that the matters should be admitted into their proper ventricles by these orifices, by the *Diastole*, to wit, into the right ventricle by the greater orifice, and into the left by the lesser; and because on the contrary it was fit that the matters should be expelled by the *Systole* from their ventricles, by the fore-mentioned orifices;

The Valves.

Therefore nature to all these orifices hath put cleaven valves, that is to say, six in the right ventricle, that there might be three to each orifice; five in the left, that the greater orifice might have three, and the lesser two, for the reason we will presently give.

How they differ.
Action.
Site.
Figure.
Substance.

These valves differ many ways: First, in action; for some of them carry in matter to the heart, others hinder that which is gone out, that it come not back again. Secondly, they differ in site, for those which bring in, have membranes without, looking in; those which carry out, have them within looking out. Thirdly, in figure, for those which carry in, have a pyramidall figure, but those which hinder the coming back again, are made in the shape of the Roman letter C. Fourthly, in substance, for the former for the most part are fleshy, or woven with fleshy fibers into certain fleshy knots ending towards the point of the heart; The latter are wholly membranous.

Number.

Fifthly, they differ in number, for there be only five which bring in, three in the right ventricle at the greater orifice, and two in the left at the lesser orifice; those which prohibit the coming back, are six in each ventricle, three at each orifice. Lastly, they differ in motion; for the fleshy ones are opened in the *diastole*, for the bringing in of blood and spirit, and contrariwise are shut in the *systole*, that they may contain all or the greater part of that they brought in. The membranous on the contrary are opened in the *systole* to give passage forth to the blood and spirits over all the body, but shut in the *diastole*, that that which is excluded might not flow back into the Heart. But you shall observe that nature hath placed only two valves at the orifice of the *Arteria venosa*, because it was needfull that this Orifice should be always open, either wholly or certainly a third part thereof; that the air might continually be drawn into the heart by this orifice in inspiration, and sent forth by expiration in the contraction of the heart. Whereby we may gather this, that there is but one third part of that air we draw into the heart in breathing, sent forth again in the form of vapor in expiration, because nature would have but one third part of the orifice to lye open for its passage out. Therefore the expiration or breathing out, and the *systole* of the heart and arteries, is shorter than the inspiration, so that we may truly say, that the inspiration, or drawing the breath in, is equally so long as the expiration is together with the rest, which is in the midst between the two motions.

Why there be only two Valves that *Arteria venosa*.

CHAP. XII.

Of the distribution of the *Vena arteriosa*, and the *Arteria venosa*.

Having hitherto shewed the originall of each of the vessels of the Heart, we must now speak of their distribution. The *Vena arteriosa*, or the Arterious vein; and the *Arteria venosa*, or the Veinous artery, each proceeding out of his proper ventricle, that is, the right and left, are divided into two large branches; one of which goes to the right and the other to the left hand, the one lying cross-ways over the other, the vein always riding over the artery, as you may understand better by the sight of your eyes, than by reading of books. These branches at their entrance of the lungs are divided into two other large branches, and each of them go to his peculiar Lobe of the lungs; and these again run almost into infinit other branches, dispersed in three places over the Lungs.

The artery always lyes under the vein.

A twofold reason why the Vein was made arterious or like an artery.

These vessels have acquired their names by reason of that transmutation of consistence, whereby the composition of a vein degenerates into an artery, and that of an artery into a vein, for the commodity of life. For this is a miracle of prudent Nature to change the coats of the vessels of the lungs; producing a vein which in its body should imitate an artery, and an artery which should represent a vein: for if the *vena arteriosa* should have retained its proper consistence, the arterious blood which is carried by it from the heart to nourish the lungs, might by reason of its subtilty penetrate through, and flow away by reason of the rarity of the veinous texture: and so nature should never have attained her con-

ceived

ceived end, that is, to nourish the Lungs, by reason of the continuall motion of their contraction and dilatation.

For nourishment cannot be assimilated to the part, unless it be put and cleave to it. Wherefore it was fit, that nature should make the body of this vein solid, that it might be immoveable, unshaken and stubborn (in respect of a vein which by its softness would have been too obsequious and yeilding to the agitation of the Lungs) that so it might have nourishment, which might be diffused into all parts thereof, and which might neither be drawn by its *diastole*, nor driven back into the heart by its *systole*. But the artery hath the consistence of a vein, that by that veinous softness according to the necessity of nature it might be the more readily contracted and dilated, to bring the air in and carry the vapours forth of the heart. Here we meet with a difficulty, which is, by what way the blood is carried out of the right into the left ventricle of the heart.

Galen thinks that there be certain holes in the partition made for that purpose; and verily there are such, but they are not perforated. Wherefore *Columbus* hath found out a new way, which is, that the blood is carryed to the lungs by the *Vena arteriosa*, and there attenuated; and carried from thence together with the air by the *Arteria venosa* to the left ventricle of the heart; this he writes truly very probably. *Botallus* in his treatise de *Catarrho* hath found out a third way, to wit, a vein, which he calls *Arteriarum nutritrix*, that is, The nurse of the arteries, which creeps a little above the Coronall to the right ear of the Heart, and then goes into the left ear thereof. But yet I am very much afraid, that this vein observed by *Botallus*, is that vessel observed by *Fallopious*, whereby the *Vena arterialis* is joyned to the *Aorta*, and by which all the vitall blood is carried for the forming and nourishment of the lungs whilst the infant is yet in the womb. Of which also *Galen* makes mention, but it had lain hid from his time to this day, but that *Fallopious* raised up the memory of it again.

Why the Artery was made like a Vein.

By what way blood may pass out of the right into the left ventricle.

The vein called the nurse of the arteries.

Fallop. initio obsar. Arteriarum. Gal. lib. 1. §. de usu part. cap. 6.

CHAP. XIII.

The distribution of the ascendent Hollow vein.

The Hollow vein rising out of the gibbous part of the Liver, and resembling (according to *Galen*) the body of a tree, is divided into two notable branches, but not of a like bigness. For the greater, by the hind part of the Liver upon the back bone & by the way, receives certain other branches from the substance of the Liver which entred not into the great trunk with the rest. You may often see this descendent branch even to the back bone upon which it lies in this its descent, covered with the substance of the liver, so that it may seem that branch proceeds not from that common trunk together with the ascendent, although indeed it alwayes doth. But the lesser branch ascends to the upper parts, and is distributed after this manner following. For first arising into the midriffe it bestows two small veins upon it, on each side one, which from that part are called *Phrenicæ*. But from thence when it arrives at the right Ear of the Heart, it makes the *Coronales*, the Coronall or Crown veins, which compass the *basis* of the heart in manner of a Crown. Thirdly, entring somewhat more deeply into its right Ear, in its greater part it produces the *vena arteriosa*. Fourthly, lifted up above the heart, on the right side it produces the vein *Azygos* or *sine pari* (that is, without a fellow) which descending to the fourth rib, (reckoning from above downwards) nourisheth the intercostall muscles and also the membranes of the eight lower ribs, on both sides, sending a branch into each of the muscles at the lower part of the rib, which may be sufficient for their nourishment. Besides also oftentimes, especially in little men, this vein *Azygos* nourishes all the spaces between all the ribs by the like branches, which it sends in the same manner to the four upper ribs. Moreover also this *Azygos* sometimes, though but seldome, is found double; that is, on each side one. Here you must chiefly observe, that this vein after it hath nourished the spaces between the lower ribs, in its remainder descends under the *Diaphragma* and is joyned on the left side to the Emulgent vein; by which it is manifest how an Abscess may be critically evacuated by the urine, in a plurisie. But this same *Azygos* is more depressed on the right side, and meets with the *Vena lumbares*, but especially with one of them, which goes down to the thigh, whereby *Fallopious* gathers that it is very convenient in the beginnings of Plurisies to open the *vena poplitis*, the vein of the Ham. Fifthly above the *Azygos* (when it is wanting there) it sends forth the branch called *Intercostalis* to the other spaces between the upper ribs; although this is sometimes seen to come from the *Axillares*, which *Sylvius* calls the *subclavia*. Sixthly, it brings forth the *Mammariæ*, so called, because in their greater part they run to the dugs between the fourth and fifth ribs, for the uses formerly mentioned; men and women have on each side one of these coming from the *Subclavia*. They are sometimes found to proceed by a certain common orifice from the hollow vein, before it be divided into the *Subclavian* branches, but it is rather in beasts than in men; these veins descending by the sides of the *sternon* yeild nourishment to the two inner muscles of the chest, to the seven intercostall muscles of the true ribs, to the *sternon* it self and

Mammariæ.

to its ligaments and gristles, as also to the *Mediastinum* & the upper part of the right muscles, and the adjacent parts. Seavently, it produces the *Cervicalis*, which on both sides through the holes of the productions of the *Vertebra's* of the neck, ascends to the head, sending many small branches into the spinall marrow through the holes by which the nerves pass, and also into the membranes, ligaments, gristles, bones, and neighbouring muscles. Eightly, the *Musculoſa* or musculous, which also arising out of the *Subclavie* is divided into two other branches, the one whereof goeth upon the breast to the paps nourishing the foremost muscles; wherefore in a bastard plurisie cupping-glasses may be fitly applied in this place.

The other branch descends to the upper muscles of the chest, but specially to that which is called *Latissimus*. The tenth is the *Axillaris*. The eleventh the *Humeralis*, of which we will treat in their place. The twelfth and last is the *Jugularis* properly so called, which is twofold, the internall and externall. The internall being the lesser doth presently on both sides from this very beginning ascend by the sides of the *Aspera Arteria* or weazon even to the mouth and skull, yeilding nourishment to the parts by which it passes, as to the next membranes and nerves. But when it comes to the *basis* of the *Cranium* it is divided into two branches, the greater whereof going back along the *basis* of the *Cranium* to the hind part thereof, sending a branch to the long muscle situate upon the *oesophagus*, it enters the *Cranium* with the small *Carotides* through the hole of the nerves of the sixth conjugation, where they become one common vessell. The lesser sending a slip to the organ of hearing by the hole called *Cæcum* (or the blind) also enters the *Cranium* and is spent in the thicker *meninx* near to the hole of the third and fourth conjugation of nerves. The externall Jugular vein being greater and fairer, most commonly simple, yet sometimes double, either presently at his beginning, or a little after, ascends superficially on both sides of the neck, between the broad muscle, or fleshy pannicle, being there easie to be discerned, and other muscles situate at the sides of the neck, into which as also into the skin it sends certain branches for nourishment.

The Figure of the hollow vein whole and freed from the rest of the body.

A, The trunk of the hollow vein. The lower *AA*, At this place of the Liver, is seated the left part of the vein, and distributeth branches to the left side.

B. Sheweth how the trunk of the hollow vein in the chest (to give way to the heart) is curved or bowed to the right hand.

Betwixt A. and B. that part of the hollow vein which is betwixt the gibbous side of the Liver and the Midriffe.

C. The left midriffe vein called *Phrenica sinistra*, from which surcles do run in a man unto the purfs of the heart, for the midriffe and it do grow together.

D. The orifice of the hollow vein which groweth unto the heart.

E. the crown-vein called *coronaria*, which like a crown compasseth the basis of the heart, and sprinkleth his surcles on the outside thereof as far as to the cone or point.

FF. The trunk of the vein *Azygos* or *non parill*, descending along the right side of the rack-bones unto the loins.

GG. the lower intercostal veins, to the branches of the vein *Azygos*, which go unto the distances

ces betwixt the ribs, and afford furcles unto the muscles which lie upon the ribs and the rack-bones, and the membranes of the chest. *H.* the division of the hollow vein into two subclavian trunks near the Jugulum under the breast-bone. *II.* the subclavian branch tending on either side unto the arm; called by some *Axillaris*. *K.* the upper intercostall vein which commonly sendeth three slips unto the distances of the upper ribs, unto which the first intercostall vein sent no branches. *LL.* the descending mammary vein: this descendeth under the breast-bone unto the right muscles of the *Abdomen*, and affordeth furcles to the distances of the gristles of the true ribs, to the *Mediaſtinum*, the muscles that lye upon the breast and the skin of the *Abdomen*. *M.* the conjunction of the mammary with the Epigaſtrick vein ascending about the navill under the right muscles. *N.* the vein of the neck called *Cervicalis*, ascending towards the skull, which alloweth furcles to those muscles that lie upon the neck. *O.* the vein called *Muscula*, which is propagated with many furcles into the muscles that occupie the lower parts of the neck and the upper parts of the chest. *P.* *Thoracica superior*, the upper chest vein which goeth to the muscles lying upon the chest, to the skin of that place and to the dugs. *Q.* the double *Scapularis* distributed into the hollow part of the shoulderblade and the neighbour muscles: so also betwixt *P.* and *R.* sometimes small veins do reach unto the glandules that are in the arm-holes. *R.* *Thoracica inferior* running downward along the sides of the chest, and especially distributed into the muscle of the arm called *Latissimus*. *S.* the inner Jugular vein which entreth into the Scull after it hath bestowed some furcles upon the rough artery. *T.* the externall Jugular vein. *V.* the division of this vein under the root of the ear *X.* a branch of the externall Jugular which goeth into the inside of the mouth, and is diversly divided into the parts therein contained. *Y.* the exterior branch distributed near the *Fauces* into the muscles of the chops and the hole skin of the head. *Z.* a portion of the branch. *y.* reaching unto the face. *a. a.* the vein of the forehead. *a.* a portion of it creeping through the temples. *e. ** a propagation that goeth unto the skin of the Nowl or *Occiput*. *a. a.* the vein called *Cephalica*, or the externall vein of the arm which others call *Humeraria*. *b.* *Muscula superior*, a propagation of the *Cephalica* vein which goeth unto the backward muscles of the neck. Betwixt *b.* and *d.* on the backside issueth a branch from the *Cephalica* which passeth unto the outside of the blade, and a portion thereof runneth betwixt the flesh and the skin. *d. d.* a vein from the *Cephalica* which attaineth unto the top of the shoulder, and is consumed into the muscle that elevateth or lifteth up the arm, and into his skin. *e. e.* a small vein from the *Cephalica* dispersed through the skin and the muscles of the arm. *f.* the division of the *Cephalica* into three parts. *g.* the first branch runneth deep unto the muscles which arise out of the externall protuberation of the arm. *h.* the second branch which goeth to make the *median* vein. *i. i.* the third branch running obliquely above the wand and the outside of the arm. *k.* from this branch certain circles are divided into the skin, the chief whereof is marked with *k.* *l.* the third branch at the wrist which is joyned at *l.* with the branch of the *Basilica* marked with *x. m.* the *Basilica* which on the right hand is called *Hepatica*, on the left hand *Lienaris*. *n. o.* a branch of the *Basilica* going to the heads of the muscles of the cubit at *n.* and to the muscles themselves at *o. p.* a notable branch of the *Basilica* running obliquely, and bestowing furcles upon the muscles that issue from the externall protuberation. This branch descendeth together with the fourth nerve. *q.* division of the *Basilica* into two branches and that is noted with *q.* is ever accompanied with an artery. *f.* a branch of this vein bestowed upon the skin of the arm. *t.* a branch of the *Basilica* which together with the branch of the *Cephalica* marked with *b.* makes the *mediana* or middle vein marked with *a. u.* a branch of the *Basilica* going to the inner head of the arm; *xx.* a branch issuing out of the former that creepeth along unto the wrist and toward the little finger conjoyning it self with a branch of the *Cephalica*. *y.* A vein running out unto the skin at the outside of the cubit. Upper *z.* a propagation issuing out of a branch of the *Basilica* marked with *t.* lower *z.* a branch of the *Basilica*. *x.* going to the inside of the Arm. *a.* the *Median* or common vein. *β.* the partition of the Median vein above the wrist: This division should have been made above *z.* the Externall branch of the partition which goeth to the outside of the head. *δ.* from which issueth a small branch to the inside. *ε.* the internall branch under *ε.* which toward the middle and the ring finger is especially disposed. *ζ.* the vein of the thumb dispersed into the mountenet or hillock, which is conjoyned with the branch noted with *δ.* *ζ.* the trunk of the hollow vein from which issue branches unto the parts seated under the liver. *η.* the fatty vein called *Adiposa sinistra*, which goeth unto the fat of the kidneys. *θ.* the two Emulgents which lead wheyey blood unto the kidneys. *λ.* the two spermaticall veins leading the matter of the seed unto the testicles. *V.* the beginning of the bodden vessell called *vas varicosam*. *κ.* the veins of the loins called *Lumbares*, which are sent in the knots or knees to the rackbones, to the marrow of the back, to the muscles that lie upon the loins, and to the *Peritonæum*. *ι.* the bifurcation of the hollow vein into the Iliack branches, which bifurcation is not unlike. *λ.* *Muscula superior*, a transverse branch going to the muscles of the *Abdomen*, and to the *Peritonæum*. *π.* the division of the left Iliack vein, into an inner branch at *π.* and an utter at *π.* *Muscula media* the utter propagation of the branch *π.* distributed through the muscles of the *coxa* and the skin of the buttocks, *ρ.* an inner propagation of the same branch.

branch ρ which goeth unto the holes of the holy bone. σ the vein called *Sacra*, which goeth to the upper holes of the holy bone. χ ψ the vein *Hypogastrica* distributed to the bladder, to the muscles of the fundament, and the neck of the womb. ϕ a vein arising from the utter branch marked with σ , which is joyned with some branches of the internall vein, near the holes or perforations of the share-bone. 3 1. a vein which when it hath passed the share-bone distributeth one branch into the cup of the *coxendix* and to the muscles of that place. κ , another small branch which runneth under the skin at the inside of the thigh. λ the congress or meeting of the foresaid vein, with a branch marked with char. 2. and distributed into the leg. 1, the *Epigastrick* vein, a propagation of the utter branch σ , perforating the *Peritonæum*, whereto as also the muscles of the *Abdomen*, and the skin it offereth branches, the chief branch of this vein is joyned with the descending mammary above the navill at *M*. Δ *Pudenda* an inner propagation of the branch. ϵ running overthwart unto the privities. Θ *Saphæna* or the ancle vein or the inner branch of the crurall trunk, which creepeth through the inside of the leg under the skin unto the tops of the toes. Λ the first interior propagation of the *Saphæna* offered to the groin. Ξ , the utter propagation thereof divided to the foreside or outside of the thigh. Π , the second propagation of the *Saphæna* going to the first muscle of the leg. Σ , the third propagation of the *Saphæna* going to the skin of the whirle-bone, and unto the hand. Φ the fourth propagation of the *Saphæna* dispersing his muscles forward and backward. Ψ branches from this unto the foreside of the inward ankle, to the upper part of the foot, and to all the toes. Ω , *Ischias minor*, called also *Muscula interior* the utter branch of the crurall trunk divided into the muscles of the *coxendix*, and to the skin of that place. 1, 2, and this also may be called *muscula*. 3, the exterior and lesser which passeth into some muscles of the leg. 2, the interior greater and deeper unto the muscles of the thigh. 3, 4, the vein called *Poplitea*, made of two crurall veins divided under the knee. 5, From this a surcle is reached upward unto the skin of the thigh. 6, but the greater part runs by the bent of the knee under the skin as far as the heel. 7, also to the skin of the outward ankle. 8, the vein called *Suralis* or calf vein, because it runneth unto the muscles that make the calf of the leg. 9, The division of the *Surall* vein into an exterior trunk 9, and an interior 14. 10, 11, the division of the exterior trunk under the knee into an externall branch, which along the brace attaineth unto the muscles of the foot. 11, and an internall. 12, 13, 12, 13, which descending along the outside of the leg to the upper part of the foot is cloven into divers branches, and in the back of the foot mixeth it self with *Poplitea*, or the ham vein. 20. 14. the interior branch of the *Surall* vein which runneth into the backside of the leg. 15, a branch hereof descending to the inside of the heel and the great toe, and is divided into divers surcles. 17, *Ischias major* issuing out of the internall trunk at 14, and running through the muscles of the calf. 18, a propagation hereof derived unto the upper part of the foot, and affording two surcles to every toe. 19, the remainder of the inner trunk. 14. behind the inner ankle, approacheth to the bottom of the foot and is consumed into all the toes. 20, the commixion of the vein *Poplitea* with the small or calf-branch at 13.

Where the externall jugular vein may be fitly opened in inflammations of the parts of the mouth.

Venæ cæcæ

Vena pupis

But when it arrives to the basis of the lower part of the head, it is divided into more branches, one whereof is carried to the muscles of the bone *Hyois*, the *Larinx*, the tongue and the lower part of the tongue (in which place it is commonly opened in the squinances, and other inflammations of the mouth) and to the coat of the nose. Another is carried to the *Dura mater*, passing on both sides through a hole situate under the bone *mastoides*, and besides, ascending to the bone of the back part of the skull, it comes obliquely to the upper part of the suture *lambdoides*, where these branches meeting together, pass into the reduplication of the *Dura mater*, dividing the fore-part of the brain, that so joined and united, they may make the *torcular*; the third ascendent is distributed upon the back-part and basis of the lower jaw, to the lips, the sides of the nose, and the muscles thereof; and in like manner to the greater corner of the eyes, to the fore-head and other parts of the face, and at length by meeting together of many branches, it makes in the forehead the vein which is called *vena recta* or *vena frontis*, that is, the forehead vein. The fourth ascending by the glandules behind the ears, after it hath sent forth many branches to them, is divided into two others, one whereof passing before, and the other behind the ear, are at length spent in the skin of the head. The fifth and last wandring over all the lower part of the head, going to the back part thereof, makes the *vena pupis*, which extended the length of the head by the sagittal suture, at length goeth so far, that it meets with the *vena frontis*, which meeting is the cause, that a vein opened in the forehead, is good in griefs of the hinder part of the head, and so on the contrary. But we must observe that in the *Cranium* of some, the *vena pupis* by one or more manifest passages sends some portion thereof to the inner part of head, so that the *vena pupis* being opened may make revulsion of the matter which causeth the internall pains of the head.

CHAP. XIII.

The distribution of the Nerves, or sinews of the sixth conjugation.

Because the distribution of the arteries cannot be well shewed, unless we violate those nerves which are carryed over the Chest, therefore before we shew the distribution of the arteries, we will as briefly as we can, prosecute the distribution of these nerves.

Now the sixth conjugation brings forth three pair of nerves; for, passing out of the skull, as it comes down to the Chest, it by the way sends forth some branches to certain muscles of the neck, and to the three ascending muscles of the *Larinx* on each side of the *Sternum* and upon the clavicles. Then the remainder descending into the Chest, is divided on each side into these three pair. The first pair makes the *Ramus costalis*. The second, the *Ramus recurrens*. The third pair, the *Ramus stomachicus*. The *Ramus costalis*, or costall branch is so called, because descending by the roots of the ribs, even to the holy bone, and joining themselves to these which proceed from each of the *Vertebra's* of the spine, they are carryed to all the naturall parts.

The *Recurrens*, or recurrent is also called, because as it were starting up from the chest, it runs upward again, but these two Recurrent nerves do not run back from the same place; but the right from below the artery, called by some the axillary, by others Subclavian, and the left from beneath the great artery, descending to the naturall parts. But each of them on each side ascending along by the weazon, even to the *Larinx*, and then they insinuate themselves by the wings of *Cartilago scutiformis*, and *Thyroides* into the proper muscles, which open and shut the *Larinx*.

By how much the nerves are nearer the original, to wit, the brain, or spinall marrow; they are by so much the softer. On the contrary, by how much they are further absent from their original, they are so much the harder and stronger, which is the reason that Nature would have these recurrent nerves to run back again upwards, that so they might be the stronger to perform the motions of the muscles of the *Larinx*. But the *Stomachicus* or stomach-branch is so called, because it descends to the stomach or ventricle. For this branch descending on both sides by the sides of the gullet, sends many branches from it into the inner substance of the lungs, into the coat thereof, into the *Pericardium* and heart; and then coming into the upper orifice of the stomach, it is spent in many branches, which folded after divers manners and wayes, chiefly makes that mouth or stomach, which is the seat of the Animall appetite (as they term it) and hunger, and the judger of things convenient or hurtfull for the stomach. But from thence they are diversly disseminated over all the body of the ventricle.

Moreover the same branch sends forth some small branches to the liver and bladder of the gall, giving each part by the way, so much sense as should be sufficiently necessary for it. Here you must note, the stomach branch descends on each side one, knit to the gullet, and by the way they divide themselves into two branches, each of which goes to the opposite side, that it may there join it self to the nerve of that side. To which purpose the right is carried above the gullet, the left below it, so that these two stomatick become four, and again these four presently become two.

Three pair of nerves of the sixth conjugation.

Ramus Costalis

Recurrens.

An anatomical Axiome.

Why nature would have the vocall nerves recurrent.
Ramus stomachicus

CHAP. XV.

The Division of the Arteries.

The Artery arising forth of the left ventricle of the heart, is presently (the two Coronall Arteries being first spread over the substance of the heart) divided into two unequal branches. The greater whereof descends to the lower parts, being distributed, as we formerly mentioned in the third book, and 22. Chapter. The lesser ascending to the upper parts, is again divided into two other unequal branches, the lesser of which ascending towards the left side, sends forth no artery from it, untill it arrive at the rib of the Chest, where it produces the subclavian artery, which is distributed after the manner following.

First, it produces the intercostall, and by it imparts life to the three intercostall muscles of the four upper ribs, and to the neighbouring places.

Secondly, it brings forth the Mammillary branch, which is distributed as the Mammillary vein is.

Thirdly, the *Cervicalis*, which ascends along the neck by the transverse productions to the *Dura mater*, being distributed as the *Vena Cervicalis* is.

Fourthly, passing out of the Chest, from the back part of the Chest, it sends forth the *musculosa*, whereby it gives life to the hind muscles of the neck, even to the back part of the head.

Fifthly,

The left branch of the ascending artery is less than the right. The distribution of the left subclavian artery into the;

ries.

Their division.
The distributi-
on of the inter-
nall branch of
the sleepey
arteries.

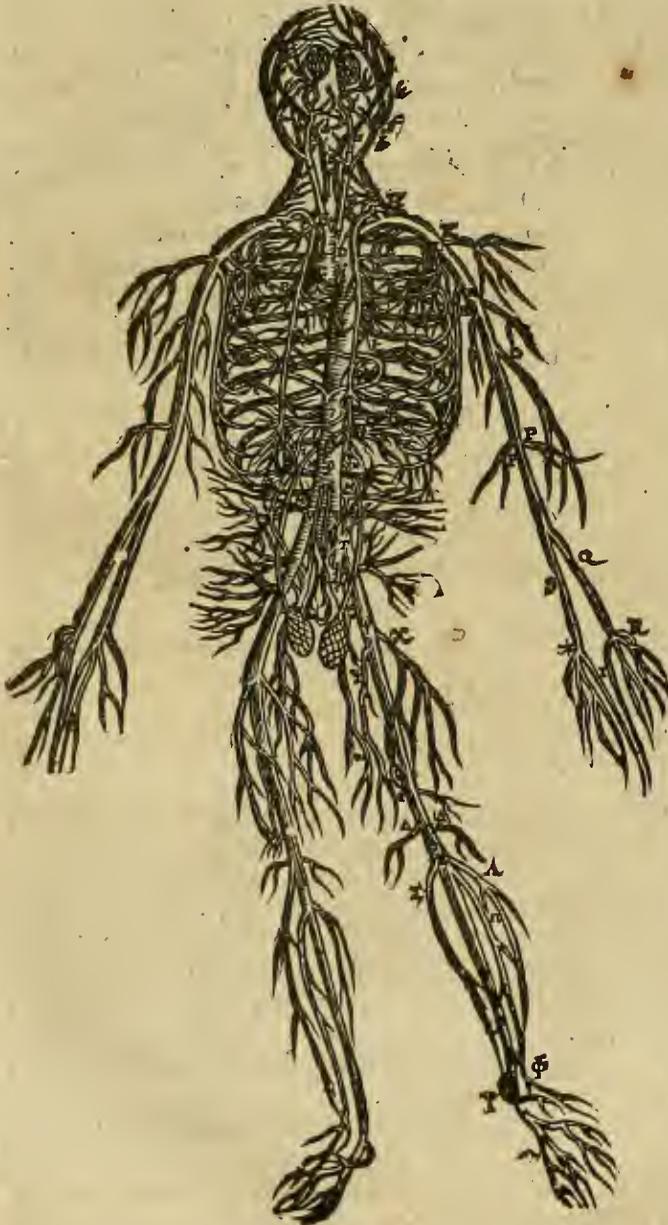

To what parts
the extremall
branch of the
sleepey artery
arrives.

Fiftly, having wholly left the Chest, it sends forth the two *Humeraria*, or shoulder arteries, the one whereof goes to the muscles of the hollow part of the shoulder blade, the other to the joynt of the arm and the muscles situate there, and the gibbous part of the shoulder blade.

Sixthly and lastly, it produces the *Thoracica*, which also is twofold, for the one goes to the fore muscles of the Chest, the other to the *Latissimus*, as we said of the vein, the remnant of it makes the *Axillaris* of that side.

The other greater branch likewise ascending by the right side, even to the first rib of the Chest, makes also the subclavian of that side, which besides those divisions it makes on this side, like those of the left side, hath also another which makes the right and left *Carotides* or sleepey arteries; which ascending undivided with a nerve of the sixth conjugation and the internall jugular vein, by the sides of the *Aspera Arteria* or windpipe, when they come to the *Pharinx*, they are divided on each side into two branches, the one internall, the other externall. The internall and greater is sent to the *Pharinx*, *Larinx*, and tongue; then entering into the head by the long hole and the back part of the upper jaw, it sends many branches to the nose, eyes, the inside of the temporal muscles and to the *Crassa meninx*, or *Dura mater*: the remainder of this branch going by the side holes of the same, that it might there make the *Plexus admirabilis* as we see. And then it is spent upon the basis of the brain abundantly diffused over the *tenuis meninx* or *Pia mater*, & then the membrane or *Plexus Choroides*. The external or lesser branch of the sleepey arteries goes to the cheeks, the temples, & behind the ears; lastly, it sends a branch into the long muscle of the neck, with which the internal Jugular vein insinuates it self into the *Dura mater*, entering by the hole of the nerves of the sixth conjugation.

The Figure of the Arteries.

- A. The orifice of the great Artery, or the beginning thereof, where it issueth out of the heart.
- B. *Coronaria*, so called, because like a crown it compasseth the basis of the heart.
- C. The division of the great artery into two trunks, V. i.
- D. The left subclavian climbing obliquely upward unto the ribs.
- E. the upper intercostall artery, or a branch which bestoweth four propagations unto the distances of the lower rib.
- F. The neck artery which through the transverse processes of the rackbones of the neck, attaineth to the scull, bestowing furcles unto the marrow and his neighbour muscles.
- G. The left Mammary artery running under the brest-bone, and to the navill. It distributeth furcles to the *Mediastinum*, the muscles of the brest, and of the *Abdomen*.
- H. *Muscula*, or a branch attaining to the backward muscles of the neck.
- I. The *Scapular* arteries which go unto the hollowness of the blade, and of the muscles that lie thereon.
- K. *Humeraria* which climbeth over the top of the shoulder
- L. *Thoracica superior*, sprinkled unto the forward muscles of the Chest. M. *Thoracica inferior*, which passing along the sides
- of the Chest, attaineth to the *broad* muscles of the arm. N. the axillarie artery running out into the arm and affording branches unto the muscles thereof. O. A branch reaching to

to the outside of the cubit lying deep. PP. Branches to the joint of the cubit with the arm. Q. The upper branch of the artery running along the *Radius* and offering furcles to the thumb, the fore-finger, and the middle finger. k. A furcle creeping unto the outside of the hand, and led betwixt the first bone of the thumb and that of the after-wrist, supporteth the fore-finger where we use to feel the pulse. S. the lower branch of the artery running along the *Vlna* and communicating furcles to the little finger, the ring finger, and the middle finger. * A little branch unto the muscles about the little finger. T. the distribution of the upper and lower branches into the hand and the fingers. V. the trunk of the great artery ascending to the *Jugulum*, and the division thereof in that place into X, Y, Z. X. the left *Carotis* or sleepey artery. Y. *Subclavian dextra* is divided into branches, as the right is divided. Z. *Carotis dextra*, called also *Apoplectica* and *Dithargica*. a. the division of the left *Carotis* in the chops. b. the exterior branch of that division going into the face, the temples, and behind the ears. c. the inner branch going to the throttle, the chops, and the tongue. d. the division hereof at the basis of the skull, into two branches which enter the *sinus* of the *Dura mater*. e. a propagation of the branch b. unto the muscles of the face. f. the distribution of the branch b. under the root of the ear. g. the fore-branch hereof creeping up the temples. h. the back branch running on the backside of the ear under the skin. i. the trunk of the great artery, descending unto the spondells of the back. kkk. the lower *Intercostal* arteries which go unto the distances of the eight lower ribs, from which are offered furcles to the marrow, and to the muscles that grow to the back and to the Chest. l. the artery of the midriffe called *Phronica* or *Diaphragmatica*. ζ, *Mesenterica Superior*, but you must note that above ζ, the trunk of the *Celiacall* artery is taken away, lest the multitude of letters in so small a Table should breed obscurity. η, θ, the right and left *emulgents* running from the *Aorta* or great arterie unto the kidneys. ι, κκ, the spermaticall arteries on either side going to the testicles. λ, the lower *Mesentericall* artery on the left below μ, running especially into the Colick gut on that side. μμ, the arteries called *Lumbares*, which run overthwart and like knees, affording furcles to the muscles that grow to the loins, and to the *Peritoneum*. μ. the lower; *Muscula superior* running into the sides of the *Abdomen* and the muscles. νν. the bifurcation of the great artery into two *iliack* trunks, and at the sides, but somewhat inward are branches which make those that are called *Sacra*. T. the division of the left *Iliack* trunk into an inner branch at ξ and an utter at φ. ξ. the inner *Iliack* branch. ο, *Muscula inferior*, the utter propagation of the inner branch going unto the muscles which cover the branch bone and the *Coxendix*. π. *Hypogastrica*, the inner propagation of the inner branch going to the bladder, the yard and the neck of the womb. ς. the umbilicall artery. ς. the remainder of the branch ξ, assuming an addition from the utter branch near φ, and so falling through the hole of the share-bone into the leg. τ. *Epigastrica*, it ascendeth upward unto the right muscle of the *Abdomen*, and about the navell is joyned with the mammary artery. υ. *Pudenda*, it creepeth overthwart the share-bone. φ. the *Crurall* trunk without the *Peritoneum*. χ. *Muscula cruralis exterior*, going into the fore muscles of the thigh. ψ. *Muscula cruralis interior*, going unto the muscles of the inside of the thigh. ω. The conjunction of this artery with the branches. ρ. *Poplitea*, going to the muscles on the backside of the thigh. ΔΔ. which communicateth small branches to the joint of the knee, and the muscles that make the calfe of the leg. Θ. the division of the *Crurall* artery under the ham into three branches. Λ. *Tibiaa exterior*, it accompanieth the brace-bone, and is consumed into the muscles. Ζ. the chief part of the *crurall* artery. Ζ. the upper and backer *Tibiaa*. Πφ. the lower and backer *Tibiaa* running unto the upper side of the foot at φ. ψ. a propagation of the *crurall* artery going to the inner and upper side of the foot, and sprinkling a branch unto the ankle. Ω. a propagation unto the lower part of the foot which affordeth furcles to each toe.

But we must note that there be more veins in a mans body, than arteries, and besides that the veins are far thicker. For there is no need for preserving the native heat in the parts themselves, either of so many, or so large instruments of that kind. Therefore you may often find veins without arteries, but never arteries without veins.

But we understand that an artery is a companion to a vein, not only when it touches it, or adheres to it by common membranes, as usually it happens; but also when it is appointed together with the vein for the use of the same part.

C H A P. XVI.

of the Thymus.

he *Thymus* is a glandule, of a soft, rare, and spongiouse substance, of large bignesse, situate in the furthest and highest part of the Chest, amongst the divisions of the subclavian or Jugular veins and arteries, as yet contained in the Chest, for this use; that it might serve these vessels for a defence against the bony hardnesse of the Chest, and besides, that as it were by this prop or stay, the distributions of these vessels

What the Thymus is.

The use.

The magni-
tude.

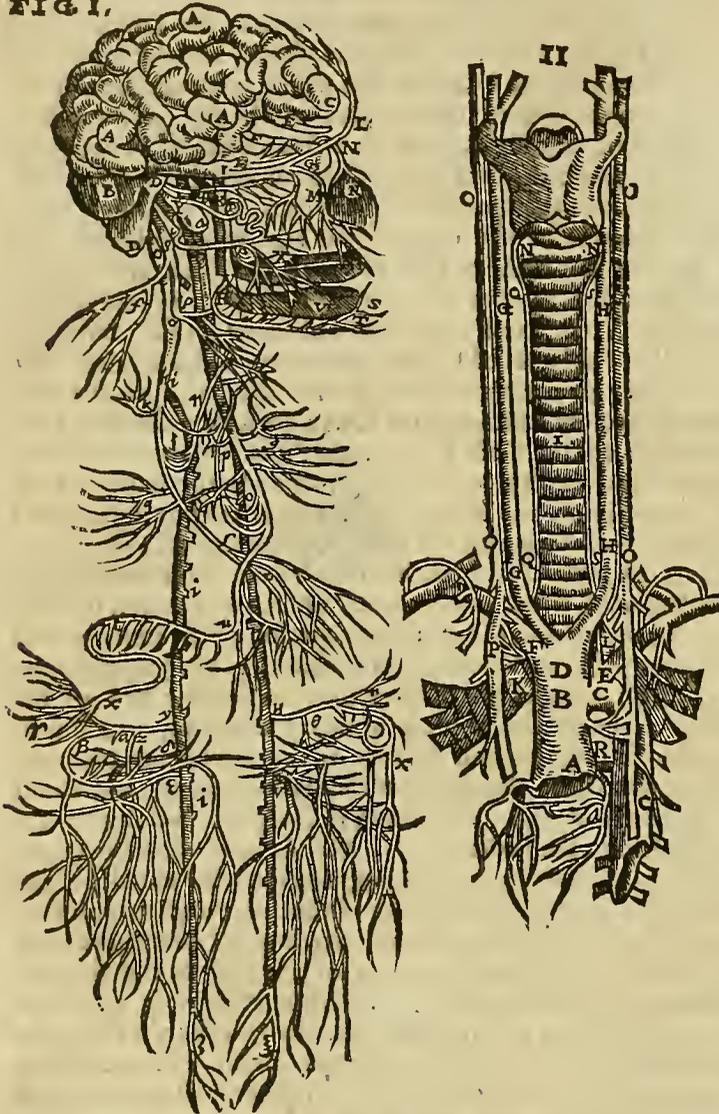

vessels might become the stronger ; for so we see that nature hath provided for others, especially such as are the more noble and worthy. This glandule appears very large in beasts and young men, but in such as have attained to full growth it is much less, and scarce to be seen.

- M. the head of the Rough Artery called the *Larinx* or *Throttle*.
- N. N. Certain Glandules or Kernells at the root of it.
- OO. the right and left nerves of the sixth and seaventh conjugation.
- P. A revolution of small branches of the right nerve to the right *Axillary* Artery.
- QQ. The right *Recurrent* Nerve.

R. A revolution of small branches of the left Nerve unto the descending trunk of the great Artery. SS. The left recurrent Nerve.

The substance.

The *Aspera Arteria* or Weazon seeing it is the instrument of voice and respiration, is of a gristly, ligamentous, and wholly various substance. For if it had been one rough, and continued body with the *Larinx* or *throttle*, it could not be neither dilated, nor compressed; opened, nor shut, neither could it order the voice according to our desire.

Composure.

It is composed of veins from the internall Jugular, of arteries arising from the *Carotides*, and of nerves proceeding from the *Recurrent* branch, of a double membrane, of which the externall comes from the *Peritoneum*; the internall, which is the stronger and woven with right fibers, from the inner coat of the mouth, the which is common with the inner coat of the *oesophagus* or gullet. And also it consists of round gristles, yet not drawn into a perfect circle, composed in manner of a channell, and mutually joyned together in order, by the ligaments that proceed from their sides and ends.

Why the back part of the Weazon is ligamentous,

These same ligaments perfect the remnant of the circle of this *Aspera Arteria*, on that part next the gullet; which is thought to be done to this end; that that softness of a ligament, might then give place, when we swallow harder and greater gobbets of meat. Of the two sorts of ligaments which are annexed to the gristles of the weazon, some tie and fasten together the rings or circles, which give means both to it, and these circles

to be drawn in length; other some bring these gristles into a perfect circle, which also yeeld them means of dilatation. These ligaments cover the inner superficies, but the gristles are placed without, to resist the incurſion of externall injuries. But we must note, that by this communion of the inner coats of the weazon and gullet, we reap this benefit in the commodiouness of the action, that one of these parts being depressed, the other is lifted up, like a rope running in a wheel or pully. For thus whilst the gullet is deprest to swallow any thing, the weazon is lifted up; and on the contrary when the stomach rises up in vomiting, the weazon is deprest. It is only one, and that seated between the *Larinx* (from which it takes its beginning) and the lungs in which it ends; first dividing it self into two large branches, the right and the left, and besides each of these entering into the substance of the lungs, is again divided into two others; to each of the Lobes one; and to conclude, these be subdivided into infinite others, through the substance of the Lobes.

All these branches are gristley even to the ends. They are situate between the ends of the *Artera venosa*, and the *Vena arteriosa*, that the entrance of the air into the heart by the *arteria venosa* might be speedier, as also the passage out of the vapour, by the *vena arteriosa*. Thus it hath connexion with these in the ends, or utmost parts thereof, but by the other parts compassing it, with the members from whence it takes them. The temperament thereof is cold and dry. The action is to carry the air to, and vapours from the lungs; that by dilating, but this by pressing the gristles together.

Why the fore-part is gristley.

The number and size. The division of the weazon through the Lobes of the Lungs.

The temper and action.

CHAP. XVIII.

Of the Gullet.

The *Oesophagus*, or Gullet, which is the passage of the meat and drink, is of a middle substance between the flesh and sinews, because it consists of one nervous membrane and another fleshy. The nervous is placed the innermost, and is continued to the inner coat of the mouth even to the Lips, (whereby it comes to pass,) that the Lips tremble in diseases which are ready to be judged by a criticall vomiting, and to the inner part of the *Aspera Arteria*; it consists of right Fibers for the attraction of the meat, which we see is sometimes so quick and forcible in hungry people, that they have scarce time to chew it, before they find it, to be pluckt down, as it were with a hand. The fleshy Coat placed without is woven with transverse fibers, to hasten the going of the meat into the stomach, and for expulsion in vomiting and breaking of wind. These two coats are continued with the two coats of the stomach, and have the like site. Besides, the Gullet hath these parts composing it, as a vein from the Gate and Hollow ascendent vein; a nerve from the sixth conjugation, an Artery from that which creeps alongst the bottome of the stomach with the *vena Gastrica*, or else from the Arteries ascending the hollow part thereof; but also besides all these vessels it may have a third coat from the membrane investing the Ribs, or *Pleura*. The magnitude of the Gullet is large enough, yet some be bigger, some less, according to the variety of bodies. The figure of it is round, that so it might be more large to swallow meat, and less subject to offence. It is placed between the back bone and weazon from the roots of the tongue even to the stomach. But as it descends alongst the back bone, when it comes to the fourth *Vertebra* of the Chest, it turns to the right side, to give way to the great Artery *Aorta* and the descendent Artery, then it turns to the left side to the stomach, or mouth of the ventricle. Nature hath fastened it to the *Diaphragma* with strong membranous ties, lest that if it had lain upon the Artery it should have hindred the passage of the vitall spirit to the lower parts. It is only one and that tyed to the forementioned parts, both by its vessels and membranes. It is of temper rather cold than hot, as all those parts, which are more nervous than fleshy, are. The Action thereof is to draw and carry down the meat, and to cast forth such things by vomit as trouble the stomach. Here must note, that whilst we swallow down, the Gullet is drawn downwards, and the weazon upwards, which is the cause that we cannot sup and blow, swallow and breath together at the same instant; which we must think to happen by Gods singular providence; to whose name be glory for everlasting, Amen.

The End of the fourth Book.

The Fifth Book,

Of the Animall parts contained in the HEAD.

C H A P. I.

A Generall description of the Head.

Having hitherto declared two generall parts of mans body, that is, the Naturall and Vital, it is now fit to betake our selves to the last, that is, the Animall, beginning with the Head.

Wherefore we will first define the head, then divide it into its parts; thirdly, describe each of these parts; fourthly, demonstrate them after the order they offer themselves to our sight in dissection.

The head therefore is the seat of the senses, the Palace and habitation of reason and wisdom, from whence as from a fountain infinite actions and commodities arise. It is seated above the rest of the

body, that the Animall spirit from thence, as from a tower, may govern and moderate the whole body, and perform all actions according to the præscript of nature. By the head we understand all that which is contained from the Crown of the head to the first *vertebra* of the neck.

The best figure of the head is round, lightly flatted on each side, *extuberating* something to the fore and hind part thereof. For from hence is taken an argument of the goodness of the senses; on the contrary, those which are exactly round, or acuminated, and sharp towards the top, are not thought good. The head is divided into the face, forehead, temples, the forepart, the crown and hind part.

By the face we understand, whatsoever is contained between the Eye-brows and the lower part of the chin. By the forehead, all the space from the eye-brows even to the Coronall Suture. By the temples, whatsoever is hollowed from the lesser corner of the eye, even to the ears. By the forepart of the head, whatsoever runs in length from the top of the forehead, or the Coronall Suture, even to the Suture *Lambdoides*, and on each side to the *Ossa petrosa*, the stony bones, or scaly Sutures. By the Crown we signifie a certain point exquisitely in the midst of the Sagittall Suture, which is sufficiently known. By the *Occiput* or hind part of the head, that which is terminated by the Suture *lambdoides*, and the first *vertebra* of the neck.

Of all these parts there be some simple, some compound, besides some are containing, some contained. Of the containing some are common to all the parts of the head, as the skin, the fleshy pannicle and *pericranium*; others are proper to certain parts, as the fleshy pannicle to the neck, face, forehead, and skin covering the *Cranium*, the common coat of the muscles to the fat and face; the skull and both the *Meninges* to the brain.

The parts contained are the substance of the brain, the four ventricles, and the bodies contained in them, the nerves, the mamillary processes; the *Plexus Choroides* or *Rete Admirabile*, the *Glandula Basilaris*, and others of which we will speak hereafter.

We must now speak of the containing parts beginning with the skin; for the order of teaching requires that we take our *Exordium* from the more simple, but first we will say something of the hair.

The hair is nothing else than an excrement generated and formed of the more gross and terrene portion of the superfluities of the third concoction, which could not be wasted by insensible transpiration. The benefit of it is, that consuming the gross and fuliginous or footy excrements of the brain it becomes a cover and ornament for the head.

This hair of the head and eye-browes have their originall from the first conformation of the infant in the womb, the rest of the hairs of the body arise and grow forth as the body grows and becomes more dry, of which sort are the hairs which cover the chin, armpoles, groins, and other parts of our bodies.

What the head is.
Why seated in the highest place.

The figure.

The parts contained.

What the hair is.
The use thereof.

CHAP. II.

Of the musculous skin of the Head, (commonly called the hairy scalp) and of the Pericranium.

THe skin which covers the skull, and is covered with the hair, is far more fleshy, thick, hard and dry than any other part of the body, especially which wants hair. The skin hath almost the like condition of quality as those parts have, which it doth simply cover, but is as it were lost in them, or grown into one with them, as in the lips and forehead with the fleshy pannicle, wherefore it is there called musculous; in other places it adheres to the gristles, as on the sides of the nostrills and corners of the Eyes, whereupon it is there called gristely.

It hath connexion with the *Pericranium*, because joyned to it, it receives nerves from the first and second *Vertebra* of the neck, and from the third conjugation of the brain which are disseminated through all its substance, whereby it comes to pass, that the wounds, contusions, and imposthumes, that happen in or upon this skin, are not to be neglected.

The * *Pericranium*, (but I suppose it should be the *Periosteum*) is a most thin membrane, which next and immediately covers all the bones of the body, and this on the head is called by a peculiar name the *Pericranium* by reason of the excellency of the *Cranium* or skull; in other bones it is termed the *Periosteum*: And as the *Pericranium* takes its originall from the *Crassa meninx* propagating it self by certain strings or threds sent forth by the futures and holes of the skull, so all other membranes of the body have their originall either from this *Pericranium*, or *Crassa meninx*, sending forth their productions, as well by the holes or passages of the head, as by these of the spinall marrow or back bone it self, even to the Holy bone.

Of which this is an argument, for in what part soever of the body a membrane is hurt, presently the hurt or sense thereof comes to the *Crassa meninx*. For so those who have but their little Toe hurt when they sneeze, or cough, perceive an increase of their pain, by the passage thereof to the brain.

The use of this *Pericranium* is to cover the skull; and to give notice of things hurtfull, by the power of the quick sense which it is endued withall, and the *Periosteum* doth the like in other bones. Besides it sustaines and fastens by the futures the *Crassa meninx* to the skull; lest it should fall by reason of its weight upon the *Pia mater*, and so hurt it, and hinder the pulsation of the brain and arteries that are plenteously spread through both the *Meninges*. Wherefore the *Pericranium* hath most strait connexion with the *Crassa meninx*, because it takes the originall from thence.

We must think the same of the other membranes of the body, which thing is very notable in the solution of the continuity of the membranes.

CHAP. III.

Of the Sutures.

THe Sutures do sew or fasten together the bones of the skull; these be five in number. Three are true and legitimate, two false and spurious. The Coronall, the first of the true Sutures, is seated in the forepart of the head, descending downwards overthwart the forepart of the head to the midst of the temples; it is so called, because *Corolle*, that is, wreaths, crowns, or garlands, are set upon that place.

The second is called the *Sagittalis*, or right future, as that which running through the crown divides the head into two equall parts, as with a straight line, running the length of it from the Coronall to the *Lambdoides* or hind Suture.

But this third Suture *Lambdoides*, is so called because it represents this Capitall greek letter Lambda Λ . You must understand this description of the Sutures, not as alwayes but as for the greater part to be thus. For there be some skulls that want the foremost Suture, or other some the hind, and sometimes such as have none of the true Sutures, but only the false and spurious. But also you shall sometimes find the *Sagittal* to run to the nose.

And oft times there be three or four Sutures in the back part of the head, so that indeed the number of the Sutures is not certain. Which also we find observed by *Cornelius Celsus*; where he writes, that *Hippocrates* was deceived by the Sutures by chance, for that he conjectured that the bones of the back part of the head, were broken; because his Probe thrust to the roughnes of the second suture *Lambdoides*, staid as at a cleft made in the bone by a stroak.

The other two are called the false, stony and scaly Sutures, by reason they are made by a scaly conjunction of the bones, but not by a toothed saw or comb-like connexion. But if any ask, why the head consists not of one bone, that so it might be the stronger: I answer

What the hairy scalp is.

Its connexion * Our Author with *Fallopins* and *Laurentius* confounds the *pericranium* and *periosteum*; but *Vesalius*, *Baubinus* and *Bartolinus* distinguish them making the *pericranium* thin and soft, and the *periosteum* most thin and nervous, and of most exquisite sense.

Why the wounds thereof must not be neglected.

The *Pericranium* and *periosteum* of the same nature.

Whence all the membranes proceed.

Why when any membranous part is hurt in any part of the body, the head is affected be consent.

The use of the *Pericranium*.

Their use and number.

Some skulls want Sutures.

Cels. lib. 8, cap. 49.

Why the skull
consists of di-
vers bones.

it is, that so it might be the safer both from internall and externall injuries. For the skull being as it were the tunnel of the chimney of this humane fabrick, to which all the smoky vapours of the whole body ascend, if it had been composed of one bone, these vapours should have had no passage forth.

In what bodies
and by what
means the *Vena*
pupis some-
times enters
into the parts
within the
skull.

Wherefore the grosser vapours pass away by the Sutures, but the more subtil by the pores of the skull; some have their Sutures very open, but others on the contrary very close.

Therefore nature hath otherwise compendiously provided for such as want Sutures; For it hath made one or two holes, some two finger's breadth from the *Lambdoides*, through which the *Vena pupis* enters into the skull, and they are of that largeness that you may put a points tag into them, that so the vapours may have free passage forth, otherwise there would be danger of death; thus nature hath been careful to provide for man against internall injuries; and in like manner against externall, for it hath made the head to consist of divers bones, that when one bone is broken the other may be safe, the violence of the stroke being stayed in the division of the bones.

In what men
one part of the
being head
stricken, the
opposite is
broken;

Whereby you may know, that if the skull chance to be broken in the opposite side to that which received the blow, that it happens either by reason of the defect of sutures, or else because they are imperfect, & too firmly closed; otherwise it is impossible such fractures should happen by reason of the separation of the bones, which breaks the violence of the blow that it can go no further.

Why we must
not apply a
Trepán to the
Sutures.

And certainly, as it is rare to find a skull without Sutures, so it is rare to find such kind of fractures. Therefore Chirurgeons must diligently observe the Sutures and site of them, lest they be deceived and take them for fractures, or unawares apply a Trepán to them, whence by breaking the veins, arteries and nervous fibers by which the internall parts communicate with the externall; there may ensue increase of pain, a violent defluxion of blood upon the *Crassa meningæ*, and the falling thereof upon the brain, (the fibers being broken by which it stuck to the *Pericranium*) and so consequently a deadly interception of the pulsion of the Brain.

CHAP. IIII.

Of the Cranium, or Skull.

What the *Cra-*
nium or skull is.

The *Cranium*, or Skull covering the brain like an Helmet, is composed and consists of seven bones, of which some are more dense, thick and hard than other some.

Why the nowl
bone is harder
than the rest.
* My Author
means by the
Os Basilare in
this place the
wedg bone: but
some Anato-
mists make it a
Synonyma of
this *Os occipi-*
tis.

The first is the *Os occipitis*, or Nowl bone seated in the back part of the head, more hard and thick than the rest, because we want hands and eyes behind, where- by we may keep or save our selves from falling.

The forehead
bone, next to
the nowl bone
is harder than
the rest.

A Cavity to be
observed in the
forehead bone.

This bone is circumscribed, or bounded by the suture *Lambdoides*, and the * *Os basilare*. The eminencies and as it were heads of this bone are received into the first *Vertebra*; for upon this the head is turned forwards and backwards, by the force of fourteen muscles and strong ligaments, which firmly tie these heads of the Nowl bone in the cavities of this first *vertebra*.

The second bone of the skull is in the forepart, and is called the *Os coronale* or *Os frontis* the forehead bone, it hath the second place in strength and thickness. It is bounded by the Coronall suture; and the ends of the wedgbone: in this forehead bone there is often found a great cavity under the upper part of the eyebrows, filled with a glutinous, gross, viscid and white matter or substance, which is thought to help to elaborate the air for the sense of smelling.

Chirurgeons must take special notice of this cavity, because when the head chanceth to be broken in that place, it may happen, that the fracture exceeds not the first table; wherefore being ignorant of this cavity, and moved with a false persuasion that they see the brain, they may think the bone wholly broken, and to press the *Meninges*, whereupon they will dilate the womb, and apply a Trepán and other instruments to lift up the second table of the bone, without any need at all, and with the manifest danger of the life of the patient.

Ossa parietalia
& *Bregmatis*.

The third and fourth bones of the skull are the *Ossa parietalia*, or *Bregmatis*, having the third place of density and thickness; although this density and thickness be different in divers places of them. For on the upper part of the head, or crown, (where that substance turns not to a bone in children untill they have all their teeth, so that it feels soft in touching, & through it you may feel the beating of the brain) these bones are very tender, so that oft times, they are no thicker than ones nail, that so the moist and vaporous excrements of the brain, shut up where the greater portion of the brain resides, may have a freer passage by the Brains *diastole* and *systole*. These two square bones are bounded above with the Sagittall suture, below with the scaly, on the forepart with the coronall, and on the hind part with the *Lambdoides*.

Ossa petrosa, or
the scaly bones.

The fifth and sixth bone of the skull are the two *Ossa petrosa* stony or scaly bones, which are

are next to the former in strength. They are bounded with the false or bastard Suture, and with part of the *Lambdoides*, and wedgbone.

The seventh is the *Os sphenoides*, *basilare*, or *Cuneiforme*, that is, the wedgbone. It is called *Basilare*, because it is (as it were) the basis of the head. To this the rest of the bones of the head are fitly fastned in their places. This bone is bounded on each side with the bones of the forehead, the stony bones, and bones of the Nosi and Palat. The figure represents a Bat, and its procces her wings.

There is besides these another bone at the basis of the forehead bone, into which the mamillary procces end, the Greeks call it *σφαιροειδης* the Latins *Cribrosum* and *Spongiosum*, the spongy bone, because it hath many holes in it not perforated in a direct passage, as in a sine, but winding and anfractuons, that the air should not by the force of attraction, presently leap or ascend into the brain, and affect it with its qualities, before it be elaborated by its lingring in the way. There are besides also, six other little bones, lying hid in the stony bones at the hole or auditory passage; on each side three, that is to say, the *Incus* or Anvill, the *Malleolus* or Hammer, and the *Stapes* or stirrop, because in their figure they represent these three things; the use of these we will declare hereafter.

But also in some skulls there are found some divisions of bones, as it were collected fragments, to the bigness almost of ones thumb, furnished and distinguished by their proper commissures, or sutures, which thing is very fit to be known to a Chirurgeon in the use of a Trepan.

Verily he may give a conjecture hereof, whilst he separates the *pericranium* from the skull, for the *pericranium* is with greater difficulty pluckt away from the sutures, because the *Crassa meninx* hath straiter connexion therewith by his nervous fibers sent forth in such places. The skulls in women are softer and thinner than in men, and in children more than in women, and in young men more than in men of a middle age. Also the *Æthiopians* or Blackmoors, as also all the people inhabiting to the South, have their skulls more hard and composed with fewer sutures.

Therefore as it is written by *Hippocrates*, such as have their Skulls the softer, the symptoms in fractures are more dangerous and to be feared in them. But the Skull by how much the softer it is, by so much it more easily and readily yeelds to the perforating Trepan. Moreover in some skulls, there be bunches standing out besides nature, made either round or cornered, which the Chirurgeon must observe for two causes; the first is for the better consideration of a blow or fracture. For in these bunches or knots, the solution of the continuity cannot be, if it seem to be stretched in length, but that the wound must penetrate to the inner parts. For in a round body there can be no long wound, but it must be deep, by the weapon forced the deeper, because as a round body touches a plain but only *in puncto* in a prick or point: so whatsoever falls only lightly or superficially upon it, only touches a point thereof. But on the contrary, a long wound must be upon a plain surface, which may be but only superficial.

Another cause is, because such bunches change the figure and site of the Sutures. And the Chirurgeon must note that the skull hath two tables, in the midst whereof the *Diploe* is; which is a spongy substance into which many veins and arteries, and a certain fleshiness are inserted, that the skull should not be so heavie, and that it might have within it self provision for the life thereof; and lastly that there might be freer passage out for the fuliginous vapors of the brain.

The upper table is thicker, denser, stronger and smoother than the lower. For this as it is the slenderer, so it is the more unequal, that it may give place to the internal veins and arteries, (which make a manifest impression into the second table on the inside thereof) from which branches enter into the skull by the holes which contain the eyes. Which thing fastens the *Crassa meninx* to the skull, and is therefore very worthy to be observed.

For in great contusions when no fracture or fissure appears in the skull by reason of the great concussion or shaking of the brain, these vessels are often broken, whence happens a flux of blood between the skull and membranes, and lastly death. But it is fit the Chirurgeon take good heed to the tender and soft substance of the *Diploe*, that when he comes to it, having passed the first table, he may carefully use his Trepan, lest by leaning too hard, it run in too violently, and hurt the membranes lying underneath it, whence convulsion and death would follow. To which danger I have found a remedy, by the happy invention of a Trepan, as I wil hereafter more at large declare in handling the wounds of the head.

Os sphenoides,
or the wedg-
bone.

Os Ethmoides,
or *cribrosum*.

The three
bones of the
auditory
passage.

By what means
a Chirurgeon
may conjecture
that there are
extraordinary
Sutures in
certain places
of the skull.

The skulls of
such as inhabit
the Southern
countreys, are
more hard and
dense.

We must
observe the
extuberancies
besides nature,
which are in
some skulls.

The site and
substance of
the *Diploe*.

There may be
a deadly rup-
ture of the
vessels of the
brain without
any fracture of
the skull.
Caution to be
had in the use
of the Trepan.

C H A P. V.

Of the Meninges, that is, the two membranes called
Dura Mater and Pia Mater.

Why the bone
Ethmoides is
perforated.

The *Crassa meninx* is one of the first and principall membranes of the body; it goes forth by the futures and the holes of the nerves that proceed out of the skull; and it passes forth by the bone *Ethmoides* perforated for that purpose, to carry smells to the brain, and purge it of excrementitious humors. This same *Crassa meninx* invests the inner coat of the Nose; also it passes forth of the great hole through which the spinall marrow passes, vested with this *Crassa meninx*, with all the nerves and membranes. For which cause if any membrane in the whole body be hurt, by reason of that continuation which it hath with the *Meninges*, it straight communicates the hurt to the head by consent.

The confi-
sience of the
Crassa meninx.
The use.

The *Crassa meninx* is thicker and harder than all other membranes in the body; whereupon it hath got the name of the *Dura mater*, besides also it begirts, produces, and defends the other membranes.

What the
Torcular is.

The use of it is to involve all the brain, and to keep it when it is dilated, that it be not hurt by the hardness of the skull. For the course of nature is such, that it always places some third thing of a middle nature, betwixt two contraries. Also the *Crassa meninx* yeelds another commodity, which is, that it carries the veins and arteries entering the skull for a long space. For they insinuate themselves into that part, where the duplicated or folded *Meninges* separate the brain from the *Cerebellum*, and so from thence they are led by the sides of the *Cerebellum*, untill they come (as it were) to the top thereof; where being united, they insinuate themselves into that other part of the *Crassa meninx*, where in like manner being duplicated and doubled, it parts the brain at the top into the right and left. These united veins run in a direct passage even to the forehead, after the manner of the Sagittall future; They have called this passage of the mutually infolded veins, the *Torcular* or *Press*, because the blood which nourishes the brain is pressed and drops from thence by the infinite mouths of these small veins. Therefore also here is another use of the *Crassa meninx*, to distinguish the brain by its duplication, being it thrusts it self deep into its body, into two parts, the fore and hind, and presently to separate the same into the right and left; that one part being hurt, the other may remain safe and sound, performing its duty to the creature, as we see in some that have the *Palsiey*. *Columbus* observed that this *Meninx* was double, and verily I have found it true by my own sight.

One part of
the brain being
hurt the other
keeps the
creature alive.
The confi-
sience of the
Pia mater.

The other *Meninx* or membrane of the brain, called *Pia mater*, is most slender interchanged with divers veins and arteries, for its own and the brains nourishment and life. This doth not only involve the brain, as the *Crassa meninx* doth, but also more deeply penetrates into the anfractuons passages thereof, that it may every where joyn and bind it to it self, not easily to be drawn from thence, by many small fibers whereby it descends even to the cavities of the ventricles thereof. Wherefore you must see it absolutely in the site as we have mentioned, and not pluck it away unless with the substance of the Brain.

The sense of
the *Meninges*.

These membranes when they are hurt or afflicted, cause grievous and most bitter torment and pain; wherefore I dare say, that these membranes are rather the authors of sense, than the brain it self, because in diseases of the Brain, as in the *Lethargy*, the party affected is troubled with little or no sense of pain.

C H A P. VI.

Of the Brain.

What the
brain is.

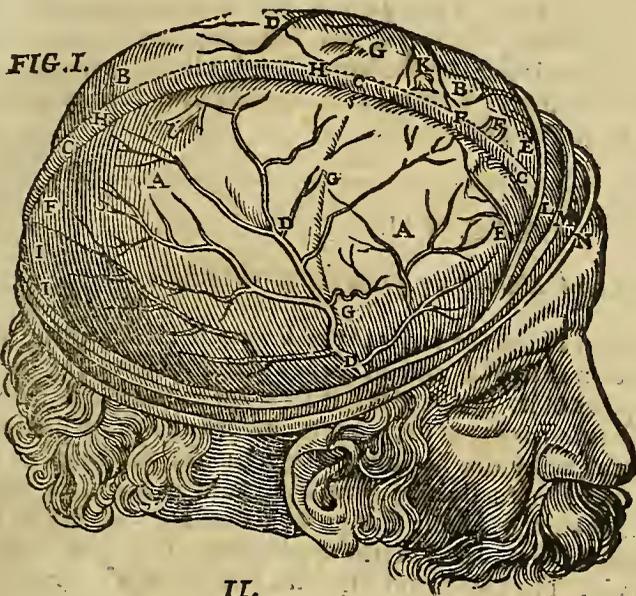

The quantity.

Temper.

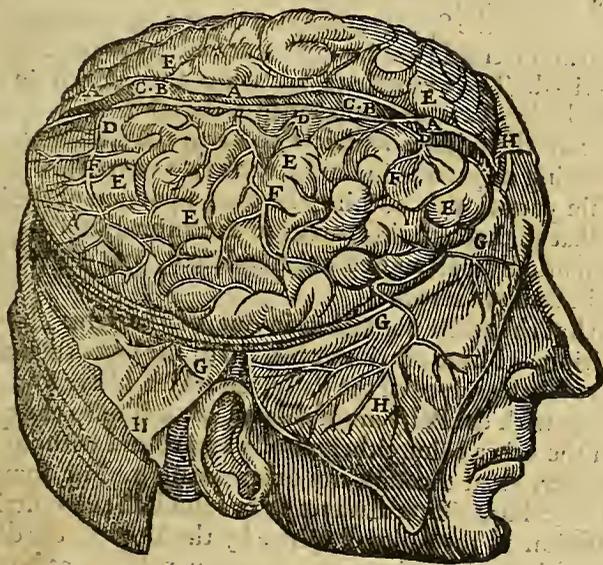

Now followeth the Brain, the beginning of the nerves and voluntary motion, the instrument of the first and principall faculty of the Soul, that is, the Animall and Rationall. Man hath this part in greater plenty then any other Creature, for it almost fills the whole skull. But if it should have filled it all, the Brain could not be moved, that is, dilated and contracted in the skull. It is of a cold and moist Temperature. The laudable temper of the Brain is known by the integrity and perfection of the internall and externall senses, the indifferency of sleep and waking, the maturity or ripeness of judgment, and constancy of opinions, from which, unless it meet with better and more probable, it is not easie to be moved.

The first figure of the Head, as it appears when the skull is taken away.
The second figure shewing the Brain, the skull and Dura mater being taken off.

II.

AA, BB. The Dura meninx or thick membrane.

CCC. The third Sinus of this membrane.

DD. The course of the veins as they run through the membrane or the second vein of the brain.

EE. The first vein of the brain.

FFF. Certain small veins which perforate the skull and reach to the pericranium or skull-skin.

GGG. Fibers of the Dura meninx passing through the Coronall Suture, which fibers make the Pericranium.

HH. fibers passing through the sagittal Suture.

II. Others passing through the Lambdall Suture.

K. A knob which useth to grow to the Sinus of the Skull.

L. A cavity in the forehead bone.

M. The skull.

N. The Pericranium of skull-skin.

Fig. 2.

AAA. A part of the Crasse meninx dividing the brain. BB. the third Sinus of the same Crasse membrane opened.

CC. the beginning of the vessels out of the third Sinus into the Pia mater.

DDD. the propagation or branches of these vessels. EEE. the Pia mater or thin meninx immediately compassing the brain. FFF. Certain vessels running through the convolutions or branches of the brain. GGG. Certain branches of veins running through the sides of the dura meninx. HHH. The thick membrane reflected downward.

You shall know the brain is more hot, by the quickness of the senses and motions of the body, by shortness of sleep, the suddain conceiving of opinions and change of them, by the slippery and failing memory, and lastly, by easily receiving hurt from hot things, as the Sun and Fire. Such as have a cold brain, are slow to learning, and to conceive other things; but they do not easily put away their once conceived opinions. They have slow motion to action, and are sleepy. Those who have a dry brain, are also slow to learn; for you shall not easily imprint any thing in dry bodies, but they are most constant retainers of those things they have once learned; also the motions of their bodies are quick and nimble. Those who have a moist brain do easily learn, but have an ill memory, for with like facility as they admit the species of things and imprint them in their minds, do they suffer them to slide and slip out of it again. So clay doth easily admit what Character or impression soever you will, but the parts of this clay which easily gave way to this impression, going together again, mixes, obliterates and confounds the same. Therefore the senses proceeding from a cold brain are dull, the motions slow, the sleep profound.

The action of the brain is to elaborate the Animall Spirit and necessary sense serving the whole body, and to subject it self as an instrument to the principall faculties, as to reason. The brain is twofold, the fore and hind. The hind by reason of its smallness is

The Action;
Number,
call

called the *Cerebellum*, (the little or After-brain). But the fore by reason of its magnitude hath retained the absolute name of the brain. Again this fore-brain is twofold, the right and left, parted by that depression, which we formerly mentioned, of the *Meninges* into the body of the brain. But this division is not to be here so absolutely taken, as though the Brain were exactly divided and separated into so many parts, but in the sense as we say the Liver and Lungs are divided a pretty way, whereas at their Basis they have one continued body. The outward surface of the Brain is soft, but the inward hard, callous & very smooth; when on the contrary, the outward appears indented and unequal with many windings, and crested as it were with many wormlike foldings.

CHAP. VII.

Of the Ventricles and Mamillary processes of the Brain.

The substance of the brain is porous and sweats forth blood.

The four ventricles thereof.

The magnitude of the upper ventricles of the brain.

The *Septum Lucidum*.

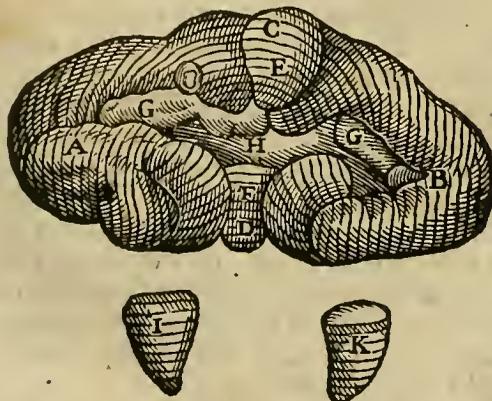

Why the Palsy of one side is not presently communicated to the other.

FOR the easie demonstration of the ventricles of the brain, it is convenient you cut away a large portion thereof, and in your cutting observe the blood sweating out of the pores of it. But besides, it is fit you consider the spongy substance by which the excrements of the brain are heaped up, to be presently strained out, and sent away by the hollow passage. In the substance of the brain you must observe four ventricles, mutually conjoynd by certain passages, by which the spirits endued with the *species* of things sensible may go from one into another. The first and two greater, one on each side are placed in the upper brain. The third is under them in the middle part of the brain. The fourth and last at the fore side of the *Cerebellum*, towards the beginning of the spinall marrow. The two formost are extended the length way of the brain in the form of a semicircle, whose horns look or bend outwards. They are spacious and large, because it was meet the Spirits contained there together with their excrements, should be there purified and clesed; but in other ventricles, the pure and already elaborate spirits are only received. These ventricles are white and smooth in their inner superficies; but that on each side they have an extuberancy at the midst of the semicircle, situate at the basis of the Pillar of the middle ventricle towards the nose under the *Septum lucidum* or cleer partition, severing or parting in sunder these two ventricles.

This *Septum lucidum*, or cleer or thin partition, is nothing else than a portion of the brain indifferently solid, but very clear, that so through this partition the animall spirits contained in these two ventricles may mutually pass and be communicated, and yet no other grosser substance may pierce the thin density thereof.

Wherefore it is not to be feared, that the water contained in one of the ventricles may pass to the other through this partition, as I have oft times observed to the great admiration of the spectators in the dead bodies of such as dyed of the Palsy, in which I have found the ventricle of that side which was taken with the Palsy much dilated; according to the quantity of the water contained therein, the other being either wholly empty and without any; or certainly no fuller than in any other, dead through any other occasion. For some affirm that there is a certain kind of waterish moisture alwayes to be found in the ventricles, which may be made by the condensation of the Animall spirits by the force of the deadly cold. But these two first ventricles of the brain go into one common passage, as both the bellows of a fornace, whereby the spirit instructed with the species of things goes into the under, or middle ventricle from the former. In these same first ventricles the *Plexus Choroides* is to be considered, and in like manner the passage by which the grosser excrements are driven or sent into the pituitary Glandule.

The third Figure represents the *Cerebellum* with the wormy processes separated from it.

AB. The right and left part of the After-brain.

CD. The anterior and posterior regions of the middle part of the After-brain.

E. The anterior wormy process.

F. The posterior wormy process.

GG. In this place the After-brain did grow to the spinall marrow.

H. The cavity in the spinall marrow maketh the

fourth ventricle. IK. The anterior and posterior processes of the brain, called *vermi-formes* or

This *Plexus Choroides* is nothing else, but a production of the *Pia mater* diversly folded with the mutuall implication of veins and arteries woven in the form of a net. These vessels are of magnitude and capacity sufficient, both to yeild life and nourishment to that particle to which they are fastened; as also for the generation of the Animall spirits, as which take fit matter from the veins stretched forth into the same *Plexus*, the hind artery and vein *Torcular*; and also from the air entring into the brain by the mamillary proecesses. But the mamillary proecesses are certain common wayes for conveyance of the air and smells into the brain, and carrying of excrements from the brain.

The *Plexus Choroides*.

The *Proecessus Mamillares*.

For thus in them who have the *Catarrhe* and *Coryza* or pose, neither the air, nor smells can penetrate into the brain; whence frequent sneezings ensue, the brain strongly moving it self to the expulsion of that which is troublesome to it. But of the excrements of the brain, whether bred there, or proceeding from some other part, some are of a fumid and vaporous nature, which breath insensibly through the Sutures of the skull; Others are gross and viscid, of which a great part is expelled by both these productions, or through each of them. For thus in the Pose you may see some who have one of their nostrils stoppt, the other running, and some who have both obstructed. The most proper benefit of the two first ventricles of the brain is to entertain the Phantase as in a convenient seat and habitation, seeing the mind there estimates and disposes in order the species of things brought in from the externall senses, that so it may receive a true judgment of them from reason which resides in the middle ventricle.

The use of the upper ventricles of the Brain.

The third ventricle is seated between the hindermost extremities of the former ventricles, and the last ventricle of the *Cerebellum*. In this six parts present themselves to our consideration, that is, the *Psalloides* or Arch, the *Conarium*, or pine Glandule, the Buttocks, wormlike productions, the Bafon and passage which is from this middle into the last & hindmost ventricle. The *Psalloides* or Arch is nothing else, but the cover of the middle ventricle, resembling a roof borne up with three staves or pillars, the one whereof is extended to the nose under the *Septum lucidum*, the two other on each side one, look towards the back part of the brain. This is the reason of this figure which is outwardly convexe and inwardly concave, to wit, that there might be free space for that motion which the Animall spirit inwardly produces, and besides that it might more easily sustain the burden of the brain lying upon it. For an arched figure is the most convenient of all other to sustain a weight.

The seat of the third ventricle of the brain. The parts to be considered in it.

What the *For-nix* or Arch is; and the use thereof.

The *Conarium* or Pine glandule, is a small Glandule of the same substance with the brain, round and somewhat long, like a Pine Apple, from whence it hath the name; this Glandule is seated over against a small hole which descends to the lowest ventricle. It hath this use, to strengthen the division of the vessels led thither with the production of the *Pia mater* for the generation of the Animall spirits, and the life and nourishment of the brain.

What the *Conarium* or pine Glandule is.

The *Nates* or Buttocks are subjected or placed under this Glandule, that is, bodies of a solid and white substance drawn out in length like a childs buttocks, especially in beasts, and chiefly in a sheep. These buttocks have such a solid substance, that so they may keep open and free the passage, or channell that runs down from the middle to the lower ventricle, by means of which the Brain participates with the *Cerebellum*.

What the *Nates* or Buttocks are.

The worm is a production of the *Cerebellum* or After-brain, to wit, a portion of the same being in the top or beginning and as it were in the entrance thereof, being like many little circles or wheels mutually knit together by slender membranes; and it is so called because it resembles those thick white worms which are found in rotten wood. It doth as it were perform the office of a porter to the formerly mentioned passage, that it may give way and entrance into the *Cerebellum*, to a necessary quantity of spirits, when need requires; lest that, if they should rush with a sodain violence into the *Cerebellum*, they might confound the imprinted notions of things to be remembred.

What the worm is.

The *Pelvis* or Bafon is a passage appointed for the carrying away of the gross excrements by the palate, and is so called because it hath the similitude and use of a Bafon or Tunnell: it descends from the third ventricle into the Glandule which is seated between the proecesses of the wedg-bone called the saddle thereof, as you may perceive by putting in a spathern. Now there remains the last of the six parts proposed to our consideration in the third ventricle, that is, the Channell or passage running from this third ventricle into the fourth, for the use formerly mentioned.

Here the *Pelvis* or Bafon is confounded with the Tunnell.

This Channell descending in its original from the Bafon, goes from thence under the buttocks into the last ventricle, the *Meninges* being perforated; which that you may shew, it is fit you put the end of a spathern through it. The benefit of a third ventricle is, that it may be as a Tribunall or Judgment-seat, to the Reasoning faculty, when the mind will draw conclusions from things seen.

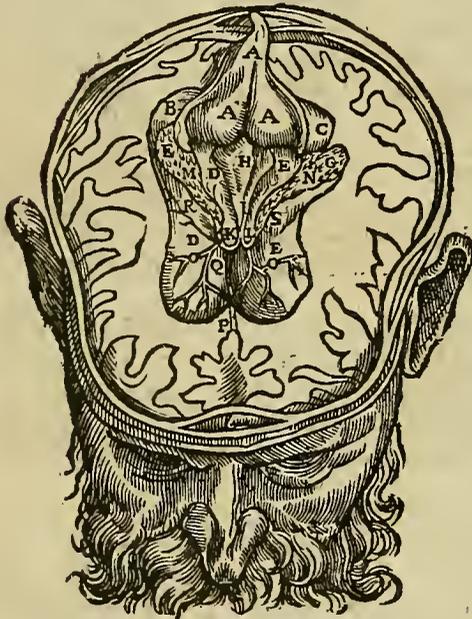

The Channell from the third into the fourth ventricle.

Figure 12. A. The Glandule. B. The *Bason* or *Tunnell* called *Pelvis* or *Infundibulum*. CDEF. The four holes through which the phlegmatick excrement issueth.

The fourth ventricle is seated in the place we formerly mentioned; it is less than the rest, but more solid; less as that which was not to receive the spirit before it was purified, and cleansed from all impurities; but more solid, that it might contain it the safer. The use thereof is, to be as a treasury and store-house of the opinion, and judgments which reason shall decree, that when need requires, we may fetch and draw them from thence as laid up in store. I know *Galen* and the Greek Physicians have not so distinguished in places the three fore-mentioned faculties; but have written that they all are all over confused through the whole substance of the brain, which opinion also *Fernelius* in his *Pathologia* hath renewed. Yet I had rather follow this opinion, as commonly received and celebrated by the *Arabian* Physicians.

The Mamillary processes are the instruments and passages of smelling being of the same substance with the brain, and like nerves, which run out from the hind horns of the upper or foremost ventricles of the brain to the *Ethmoides* and spongy bones of the nose, that hence they may receive the divers kinds of smells, and carry them into the Brain. But although they be like nerves, yet they are not accounted nerves because they go not out of the skull.

The fourth ventricle of the brain.

The use of the Mamillary processes.

CHAP. VIII.

Of the seven conjugations of the Nerves of the Brain; so called, because they always shew the Nerves conjugated and doubled, that is, on each side one.

He nerves are the ways and instruments of the Animall spirit and faculty, as of which those spirits are vehicles, as long as they are contained in the brain; they consist of the only and simple marrowey substance of the brain, or spinall marrow. But passing forth of the brain, they have another membranous substance which involves them joyned with them from the two membranes of the brain; and according to the opinion of some Anatomists, they have also a third from the ligaments drawn as well from divers others, as from these by which they are tyed to the *Vertebra's*; Yet this opinion seems absurd to me, seeing such a membrane, as that which is insensible, wholly repugnes the condition of a nerve, which is to give sense to the parts to which it is inserted.

The magnitude of the nerves is different, according to the divers necessity of sense incident to the parts into which they are inserted. Their figure is round, and long, like to a conduit pipe to carry water in; the membranes of the brain, with which the nerves are covered, being dilated and stretched over them, after the same manner that the processes of the *Peritonæum* involves the spermatick vessels, with which they go down to the Testicles, and take life and nourishment by the capillary veins and arteries, which descend to them with the membranes. They are made for this use, that they may impart sense to the sensitive parts, and motion to these that are fit to be moved. All the nerves descend from the brain either mediately or immediately; their Number is seven and thirty pair, or conjugations, whereof seven have their originall immediately from the brain, the other thirty from the spinall marrow.

The first conjugation of the nerves of the brain is thicker than all the rest, and goes to the eyes, to carry the visive spirit to them. These arising from divers parts of the brain, in the middle way before they go out of the skull meet together crosswise like the Iron of a Mill (which is fastened in the upper stone) going into one common passage with their cavities not visible to the eye; that so the spirits brought by those two nerves may be communicated, and they are mutually joyned and meet together so, that being driven back from one eye they may flie back into the other. An argument whereof may be drawn from such as aim at any thing, who shutting one of their eyes see more accurately; because the force of the neighbouring spirits united into one eye, is more strong than when it is dispersed into both. This conjugation when it comes into the glassie humor, is spent in the structure of the net-like coat which contains this humor on the back part.

The second conjugation goes into many parts, at its passing forth of the skull; and in the bottom of the circle of the eye it is distributed into the seven muscles moving the eyes.

The third is twofold, in the passage out of the skull it is likewise divided into many branches, of which some are carryed to the temporall muscles, into the *Masseteres* or grinding muscles into the skin of the face, forehead and nose; Other some are sent into the upper part of the cheek, and the parts belonging to it, as into the teeth, gums and the muscles of the upper lip; and those which are called the round which incompass the mouth on the inside; the last are wasted in the coat of the tongue, to bestow upon it the sense of tasting.

The fourth conjugation is much smaller, and is almost wholly wasted upon the coat of the Palat of the mouth, to endue it also with the sense of tasting.

The fifth at its originall and having not as yet passed forth of the skull, is divided into two,

and sends, the greater portion thereof to the hole of the ear, or passage of hearing, that it may support the auditory faculty; and it sends forth the other lesser portion thereof to the temporall muscles by the passage next to it; by which the second conjugation passes forth.

The sixth being the greatest next to the first, passing entire forth of the skull, imparts some small branches to certain muscles of the neck and throttle, and then descending into the chest, it makes the recurrent nerves, and dispersed over all the parts of the two lower bellies, it passes even to the bladder and testicles, as we shewed in the former book.

The seventh is inserted and spent upon the muscles of the bone *Hyoid*, the tongue, and some of the throttle, to give them motion; it passes forth of the skull by the hole of the nowl bone at the extuberancies thereof.

The seventh figure shewing the eighth conjugation of the Nerves of the Brain.

Surcles from the seventh conjugation to the muscles of the tongue, the bone *Hyoid* and the Larinx. op q 1. three holes; through the hole o the phlegm issueth out of the third ventricle of the brain to the Tunnell, and at pq. is the passage of the *Soporary* arteries to the ventricles of the Brain.

CHAP. IX.

Of the Rete Mirabile, or wonderfull Net, and of the Wedg-bone.

THe Animall spirit is made of the vitall, sent from the heart by the internall sleepey Arteries to the brain. For it was requisite that it should be the more elaborate, because the action of the Animall is more excellent than that of the vitall; nature hath framed a texture of Arteries in many places running cross one another, in the form of a Net divers times doubled; (whereupon it had the name of the wonderfull Net) that so the spirit by longer delay in these Labyrinthian or maze-like turnings, might be perfectly concocted and elaborate, and attain to a greater fitness to perform the Animall functions.

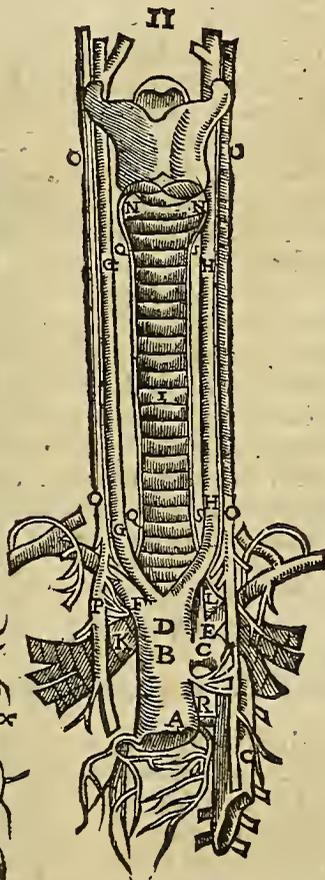

This wonderfull Net situate at the sides of the *Apophyses clinoides* or productions of the wedg-bone, is twofold; that is, divided by the pituitary Glandule which is situate between the said *Apophyses Clinoides*, having the wedgbone lying under them, next to the *Crassa Membrana*, being perforated on the right and left side, next to which lye bones as rare as a sponge even to the Palat, by which the Phlegme is purged by the mouth and nose; and therefore, I think, that spittle flows, which such as have a moist brain, continually spit out of their mouth.

The existence of the Animall spirit. What the Rete Mirabile is.

The site and number.

The Eight Figure of the brain.

FIG. I.

- A, The brain.
- B, the *Cerebellum* or after-brain.
- C, a process of the brain, but not that which is called *Mamillaris*.
- DD. The marrow of the back as it is yet within the skull.
- E, the *Mamillary* process or instrument of smelling.
- F, the optick nerve.
- G, the coat of the eye into which the optick nerve is spread.
- H, the nerve that moveth the eye or the second pair.
- I, the third conjugation, or the harder and lesser branch of the nerves of the third conjugation brought forward.
- K, the fourth conjugation of the greater and thicker nerve of the third pair bending downward.
- L, a branch of the nerve marked with I, which goeth to the fore head.
- M, another branch of the nerve I, reaching to the upper jaw. NN, a nerve proceeding from the branch I, inixed or woven with the coat of the nose. O, the nerve of the temporall muscle issuing from the branch I. P, a nerve contorted of the nerves K and b. Q, a nerve proceeding from the branch K, to the sockets of the upper teeth.
- R, a nerve creeping from the nerve K to the lower jaw. S, a fucile of the branch R, offered to the lower lip. TT, other fuciles from the branch R, attaining to the lower teeth. VV, a branch of the nerve K, diffused into the coat of the tongue. XX, the fourth pair of sinews which go into the coat of the palat. Y, the fifth pair of sinews which are the nerves of

hearing. a, the membrane of the ear, unto which that fifth nerve goeth. bc, two small branches of the fifth conjugation uniting themselves with the nerve P. d, the eighth conjugation or a nerve of the fifth pair attaining unto the face. ee, the sixth pair of nerves. f, a branch from the nerve e, reaching to the muscles of the neck. g, small branches detived unto the throtle or *larinx*. h, the bifurcation of the nerve into two branches. iii, an inner branch hanging to the rackbones, and strengthening the *intercostall* nerves, and is therefore called *intercostallid*. kk, Surcles of the outer branch going to the heads of the muscles, to the breast-bone and to the collar-bones. lm, branches of the right nerve l, making the right *Recurrent* nerve. mn, the insertion of the recurrent sinews into the muscles of the *larinx*. op, branches of the left nerve making the left recurrent sinew p. qq, branches from the first conjugation going to the coat of the lungs. r, small nerves of the heart and of the purse thereof called the *Pericardium*, as also some approaching to the coats of the lungs. s, nerves on either side sent to the stomach. t, the right stomach nerve going to the left orifice of the stomach. uu, the left stomach nerve going to the right orifice of the stomach. x, a nerve from the branch u, passing into the hollownes of the liver. y, the nerve belonging to the right side of the kell. z, the nerve belonging to the colick gut. a, a nerve creeping to the gut called *duodenum* and the

the beginning of the *jejunum* or empty gut. *β*, a nerve implanted in the right side of the bottom of the stomach. *γ*, a nerve belonging to the liver & bladder of gall. *δ*, a nerve reaching unto the right kidney. *ε*, a branch reaching the *Mesenterium* and the guts. *ζ*, a branch sprinkled to the right part of the bladder. *η*, a branch going through the left part of the kel. *θ*, furcles derived to the colick gut and the kel. *κ*, small branches inserted into the spleen. *λ*, a nerve approaching to the left side of the bottom of the stomach. *μ*, a branch belonging to the left side of the *Mesenterium* and the guts. *ν*, a branch which attaineth to the left kidney. *ξ*, small nerves creeping through the left side of the bladder. *ο*, the seven pair of sinews. *π*, a branch derived from the sixth conjugation to the muscles which arise from the process called *Styloides*. *ρ*, a branch of the seventh conjugation which goeth to the muscles of the tongue, of the bone *hyois*, and of the throttle or *larinx*. *ς*, a conjunction or coition of the 6. and 7. pair into one Nerve.

What the *Apophyses Clinoides* are.

Whether the *Rese mirabilis* differ from the *Plexus Chorooides*.

These *Apophyses clinoides* are certain productions of the *Os basillare* or wedg-bone, (called the Saddle thereof,) between which, as I said, the pituitary glandule lies with part of the wonderfull net. There is a great controversie amongst anatomists concerning this part; for *Vesalius* denies that it is in man, *Columbus* admits it, yet he seems to confound it with the *Plexus Choroides*. Truly I have observed it alwayes after the manner, as *Sylvius* alleges against *Vesalius*. It remains, that we recite the perforations of the skull, because the knowledg of these much conduces to the understanding of the insertions of the veins, arteries and nerves.

CHAP. X.

Of the holes of the inner Basis of the skull.

IN the first place are reckoned the holes of the bone *Ethmoides*; then those of the optick nerves. Thirdly, of the nerves moving the eyes. Fourthly, of that portion, of the nerves of the fourth conjugation which go to the temporall muscles. Fifthly are reckoned, these holes scarce visible, situate under the pituitary glandule, by which the spittle is evacuated. Sixthly, that hole which is in the wedg-bone made for the entrance of the internall sleepy Arteries, composing the wonderfull Net, and then passing into the brain by a great slit. That perforation which we reckon in the seventh place is commonly double, made for the entrance of one of the branches of the internall Jugular vein. The eighth hole is somewhat long, of an ovall figure, by which, part of the third conjugation and all the fourth conjugation passes forth. The ninth are the auditory passages. The tenth are very small holes, and give way to the vein and artery going to the auditory passage, above the *foramen cæcum*. In the eleventh place are reckoned the perforations which yeeld passage forth to the sixth pair of nerves, to part of the sleepy Arteries, and of the internall Jugular. In the twelfth those which yeeld a way out to the seventh conjugation. The great hole of the Nowl-bone through which the spinall marrow passes, is reckoned the thirteenth. The fourteenth is that, which most commonly is behind that great hole, by which the Cervicall veins and arteries enter in.

CHAP. XI.

Of the perforations of the externall Basis of the Brain.

HERE is a hole on each side at the Eye-brows, by which passes a small nerve from the third conjugation coming out of the cavity of the Orb of the eye, and going by the forehead bone to the eye-brows, that it may give motion to the two muscles of the upper eye-brow and forehead. Yet oftentimes the hole is but to be seen on one side, oft times there is a cleft in stead thereof, otherwhiles it is not perforated nor cleft at all. The second, is the perforation of the greater corner of the ey, by which a portion of the nerves of the third conjugation descends to the coat of the nose; in this hole the *Glandula Lachrymalis* is seated. The third is seated under the eye, that it may give way to the other portion of the nerves of the third conjugation going to the partt of the face, and the teeth of the upper jaw. The fourth is at the beginning of the palat, amongst the cutting or shearing teeth, through which a vein, an artery and the coat of the palat passes out. In the fifth order are reckoned the perforations of the palat, by which the nerves descend from the fourth conjugation, to give, or cause the taste. In the sixth order are ranked the holes of the palat serving for the respiration, and the flegm falling from the brain by the nostrils. And there is a cleft under the yolk bone ascending into the Orb of the eye, by which there is a way, as wel for the nerves of the third conjugation to the temporall muscles, as also for certain veins and arteries. But also there is noted another hole at the manillary process, which is not perforated in the judgment of the sense. Besides there is thought to be another at the hind root of the same process, by which a certain small vein passes from the Jugular to the *Tercular*. But I have only noted these three passages by the way, because there is so much variety in them, that nothing can be certainly said of them. ¶

CHAP. XII.

Of the Spinall Marrow, or Pith of the Back.

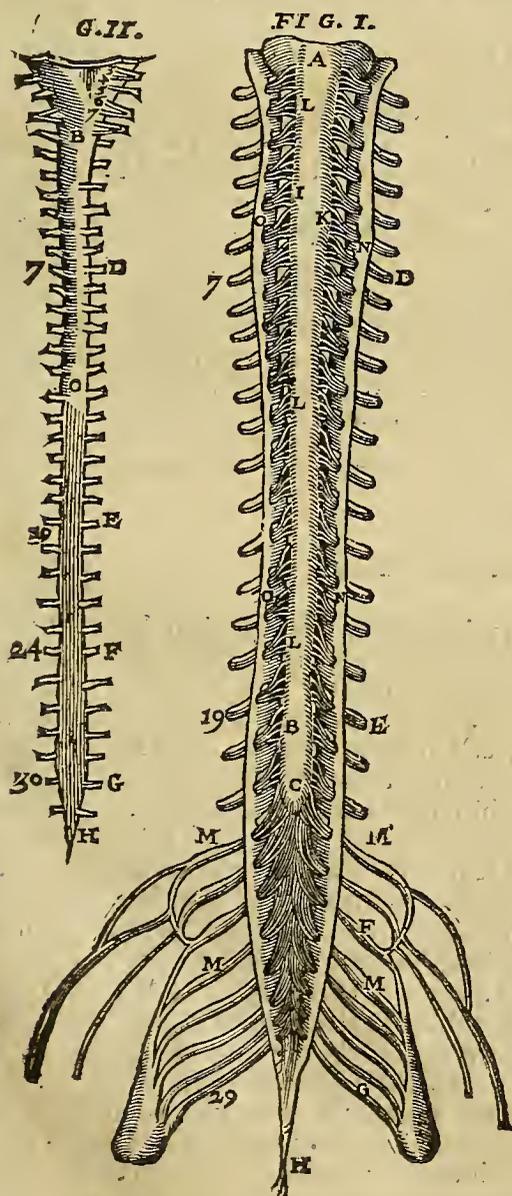

The Spinall Marrow is like a River running from the fountain of the brain. This sends nerves for sense and motion to all the neighbouring parts under the head, spreading its branches as from the body of a tree. These branches, as we shall hereafter shew, are on each side thirty. This same spinall marrow is covered with the two membranes investing the brain, distinguished by no distance of place, as in the brain. But also it hath another membrane added to these, being very hard and dense, which keeps it from being broken and violated by the violent bending of the body forwards and about. The diseases of this marrow do almost cause the like Symptoms, as the diseases of the brain; For they hurt the sense and motion of all the parts lying beneath them: as for example; If any of the *vertebra's* of the back bone, be moved out of their place, there follows a distortion or wresting aside of the Marrow; but then especially if it happen that one of the *vertebra's* be strained, so sharp and bitter a compression urges the marrow by reason of the bony body of the *vertebra*, that it will either rend it, or certainly hinder the passage of the spirit by it. But by these same holes of the *vertebra's* the veins and arteries go to the spinall marrow for to give life and nourishment to it, as the nerves by them pass forth into all the lower parts of the body.

Figure 1. sheweth the form of the spinall marrow properly so called, with its membranes, and the nerves proceeding from it.

Figure 2. the spinall marrow naked and bare, together with its nerves, as most part of Anatomists have described it.

The tenth Figure of the spinall marrow.

- A. The beginning of the spinall marrow where it falls out of the skull.
 B. The thickness thereof in the spondels or rack bones of the loins.
 C. The division thereof into strings, or hairy threds.
 D. The seven nerves of the neck.
 From D. to E. or from 7. to 19. shew the nerves of the back.
 From E. to F. the nerves of the loins.
 From F. to G. the nerves of the *Os sacrum* or holy bone.
 H. The end of the marrow.
 IKL. Do shew how the nerves do issue from the marrow in strings.
 MM. The knots of the sinews made of the conjunction of those strings.
 NO. The membranes that invest the marrow.

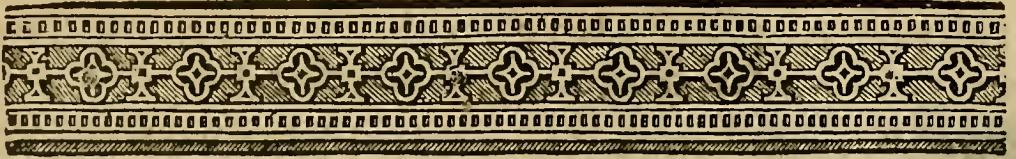

Figure 2.

- A. The beginning of the spinall marrow in the skull.
 3, 4, 5, 6, 7. these Characters shew (according to *Vesalius* opinion) how the conjugations of the nerves of the brain do take their originall from the marrow remaining yet within the skull.
 B. The egress of the spinall marrow out of the skull.
 C. The cords or strings whereinto it is divided.
 D 7. The marrow of the neck and seven pair of sinews. E 19. Twelve pair or conjugations of nerves proceeding from the marrow of the Chest.
 F 24. The marrow of the loins and 5. pair of sinews. G 30. the marrow of the holy bone and 6. pair of sinews.
 H. The extremity or end of the spinall marrow.

What the Spinall marrow is:

The coats of the spinall marrow.

The diseases from the hurting of the spinall marrow.

The Sixth Book,

Treating of the *Muscles and Bones*, and the other *Extreme parts of the BODY.*

The Preface.

Eraventure some may wonder that I have ended my fifth book of Anatomy, before I have fully described all the parts of the head, the which seemed as it were only appointed for that purpose. Therefore I must yeeld a reason of this my intention. I have a desire in one Treatise and as it were at one breath, to prosecute the Anatomy of the Muscles. Wherefore because the parts of the head not yet described, principally consist of the Muscles, therefore I desired to comprehend them together with this same description of the extreme parts of the body; beginning at the upper part of the face; to wit,

The description of the bones being unknown, it must necessarily follow that the original and insertion of the muscles must be so also.

The endowments of the face. The countenance is the bewrayer of the will,

the eyes: but having first described the bones of the face, without the knowledg of which it is impossible to shew the original and insertion of the Muscles. We have formerly noted, that by the face is meant whatsoever lyes from the Eye-browes even to the Chin. In which there is such admirable industry of nature, that of the infinite multitude of men you cannot find two so like, but that they may be distinguished by some unlikenesse in their faces; also it hath adorned this part with such exquisite beauty, that many have dyed by longing to enjoy the beauty desired by them. This same face albeit it little exceeds halfe a foot, yet it indicates and plainly intimates by the sodain changes thereof, what affections and passions of hope, fear, sorrow and delight possesse our minds; and what state our bodies are in, sound, sick, or neither. Wherefore seeing the face is of so much moment, let us return to the Anatomical description thereof, which that wee may easily and plainly perform we will begin with the bones thereof, whereby, as we formerly said, the original and insertion of the Muscles may be more certain and manifest to us.

CHAP. I.

Of the bones of the Face.

Bones in each orb of the Eye.

What the Zygoma is, and what use it hath.

The Ægylops. The two bones of the nose. The two inner bones of the palat.

He bones of the face are 16, or 17. in number. And first, there be reckoned 6. about the orbs of the eyes, that is 3. to each orb, of which one is the bigger, another lesser, and the third between both; each of these touch the forehead bone in their upper part. Besides, the greater is joyned with a suture to the proceſſe of the stony bone, and so makes the *Zygoma*, that is, the *Os Jugale* or yoaik bone, framed by nature for preservation of the temporall muscle. The lesser is seated at the greater corner of the eye, in which there is a hole perforated to the nose, and in this is the glandule in which the Ægylops doth breed. The middle is in the bottom, or inner part of the orb, very slender and as it were of a membranous thinnesse: then follow the two bones of the nose which are joined to the forehead bone by a suture, but on the foreside between themselves by harmony. But on the back or hind part with two other bones, on each side one, which descending from the bone of the forehead (to which also they are joined by a suture) receive all the teeth. These two in *Galens* opinion are seldome found separated. But these are the thickest of all the bones of the face hitherto mentioned, knit by a suture with the greatest bone of the orb, on the back part with the wedg-bone, on the inner side with the two little inner bones of the palat, which on the inside make the extremity thereof, whereby it comes to passe, that we may call these bones the hinder, or inner bones of the palat. They reckon one of these bones the eleventh and the other the twelfth bone of the head; these two little bones on their sides next to the winged productions of the wedg-bone, receive on each side one of the nerves of the fourth

fourth conjugation, which in the former book, we said were spent upon the membrane of the palat.

And in *Galens* opinion there be other two in the lower Jaw, joined at the middle of the chin; although some think it but one bone, because by the judgement of sense there appears no division or separation therein. But you may see in children how true this their supposition is, for in men of perfect growth it appears but one bone; these two are reckoned for the thirteenth and fourteenth bones. Now these two bones making the lower Jaw, have in their back part on each side two productions, as they lye to the upper Jaw, the one of which represents the point of a sword, and is called the *Corone*; the other is obtuse and round; which is inserted into the cavity seated at the root of the proësse of the stony bone, neer to the passage of the ear.

This may be strained to the forepart by violent gaping, by retraction of the muscles arising from the wing-like proësses, and ending at the lower angles of the broader part of the same Jaw.

This Jaw is hollow as also the upper, especially in the back-part, being filled with a white and glutinous humour, conducing to the growth of the teeth. This humour hath its matter from the blood brought thither by the vessels, veins, arteries and nerves from the third conjugation entring in here by a passage large enough. Whereby it comes to passe, that this part is not only nourished and lives, but also the teeth receive sense by the benefit of the nerves entring thither with the vein and artery, by smal holes to be seen at the lower roots of the teeth; and thence it is that a beating pain may be perceived in the tooth-ach, because the defluxion may be by the arteries; or rather because the humour flowing to the roots of the teeth, may presse the artery in that place; beside also you may see some appearance of a nervous substance in the root of a tooth newly pluckt out.

But also you must consider, that this Jaw from its inner capacity produces at the sides of the chin two nerves of a sufficient magnitude, over against the lower dog-teeth, and the first of the smaller grinding teeth, as I have noted in the description of the nerves of the third conjugation. I have thought good to put thee in mind of these, that when thou shalt have occasion to make incision in these places, thou maist warily and discreetly handle the matter, that these parts receive no harme.

There remains another bone seated above the palat, from which the gristly partition of the nose arises, being omitted of all the Anatomists, for as much as I know. Now therefore that you may the better remember the number of the bones of the face, I will here make a repetition of them.

There are six of the orbs of the eyes, at each three. The seventh and eight wee may call the Nasall, or nose bones. The ninth and tenth the Jaw-bones. The eleventh and twelfth are called the innce bones of the palat. The thirteenth and fourteenth the bones of the lower Jaw. The partition of the nose may be reckoned the fiftenth.

Now it remains having spoken of these bones, that wee treat of the teeth, the Eyebrowes, the skin, the fleshy pannicle, the Muscles, and lastly, the other parts of the face.

CHAP. II.

Of the Teeth.

The teeth are of the number of the bones, and those which have the most have thirty two, that is, sixteen above, and so many below; of which in the forepart of the mouth there are four above and as many beneath, which are called *Incisorii* cutting or shearing teeth, to cut in sunder the meat, and they have but one root. To these are joynd two in each Jaw, that is, on each side of the other one, which are called *Canini dentes*, Dog-teeth, because they are sharp and strong like dogs-teeth; these also have but one root, but that is far longer then the other have.

Then follow the *Molares* or Grinders, on each side five, that is, ten above, and as many below, that they may grind, chew, and break the meat, that so it may be the sooner concocted in the stomach; for so they vulgarly think, that meat well chewed is halfe concocted; those grinders which are fastened in the upper Jaw, have most commonly three roots, and oft-times four. But these which are fastened in the lower, have only two roots, and sometimes three, because this lower jaw is harder than the upper so that it cannot be so easily hollowed, or else because these teeth being fixed and firmly seated, needed not so many staves as the upper, which as it were hang out of their seats. The shearing teeth cut the meat because they are broad and sharp; the dog-teeth break it, because they are sharp pointed and firm; but the grinders being hard, broad and sharp, chew and grind it afunder. But if the grinders had been smooth, they could not fitly have performed their duty, for all things are chewed and broken afunder more easily by that which is rough and unequal.

Wherefore they sharpen their Millstones when they are smoother than they should be,

The two bones of the Jaw.

Two productions on each side of the lower Jaw.

The Luxation of the lower Jaw.

The lower Jaw filled with a marrowy humour.

How the teeth feel.

Why the teeth have a beating pain.

The nerves of the lower Jaw must be observed.

The bone of the nose above the palat, or the partition of the nose.

The teeth are bones.

The shearing teeth. The Dogteeth.

The Grinding teeth.

Why the upper grinding teeth have more roots. The use of the teeth.

The teeth are fastened in the jaws by *Gomphosis*.

The fastening of the teeth in the jaws is to be observed.

Wherein the teeth differ from the other bones.

For what use the teeth have sense.

The fore-teeth help for the articulation of the voice.

by picking them with a sharp Iron. The teeth are fastened in the jaws by *Gomphosis*, that is, as a stake or nail, so are they fixed into the holes of their jaws; for they adhere so firmly thereto in some, that when they are pluckt out, part thereof follows together with the tooth; which I have often observed to have been also with great effusion of blood. This adhesion of the teeth fastened in their jaws, is besides strengthened with a ligament, which applies it selfe to their roots together with the nerve and vessels. The teeth differ from the other bones, because they have action whilst they chew the meat; because being lost they may be regenerated, and for that they grow as long as the party lives, for otherwise by the continuall use of chawing they would be worn and wasted away by one another. You may perceive this by any that have lost one of their teeth, for that which is opposite to it becomes longer than the rest, because it is not worn by its opposite. Besides also they are more hard and solid than the rest of the bones, and indued with a quick sense by reason of the nerves of the third conjugation which insert themselves into their roots; for if you rub, or grind a tooth newly pluckt out, you may see the remains of the nerve; they have such quick sense, that with the tongue they might judg of tastes. But how feel the teeth, seeing they may be filed without pain? *Fallopius* answers, that the teeth feel not in their upper or exterior part, but only by a membrane which they have within. And the teeth have another use, especially the fore-teeth, which is, they serve for distinct and articulate pronuntiation; for those that want them fault in speaking, as also such as have them too short, or too long, or ill ranked. Besides, children speak not distinctly before they have their fore-teeth. And you must note that the infant as yet shut up in its mothers womb hath solid and bony teeth; which you may perceive by dissecting it presently after it is born.

But even as there are two large cavities in the forehead bone at the eye-browes, filled with a viscous humor, serving for the smelling; and in like manner, the air shut up in the mamillary processes is for hearing; so in the jaws there be two cavities furnished with a viscid humour for the nourishment of the teeth.

CHAP. III.

Of the Broad Muscle.

Now we should prosecute the containing parts of the face; to wit, the skin, the fleshy pannicle and fat; but because they have been spoken of sufficiently before, I will only describe the fleshy pannicle, before I come to the dissection of the eye, that wee may the more easily understand all the motions performed by it, whether in the face or forehead.

First, that you may more easily see it, you must curiously separate the skin in some part of the face. For unlesse you take good heed, you will pluck away the fleshy pannicle together with the skin, as also this broad muscle to which it immediately adheres, and in some places so closely and firmly, as in the lips, eye-lids and the whole forehead, that it cannot be separated from it, Nature hath given motion, or a moving force; to this broad muscle, that whilst it extends, or contracts it self, it might serve to shut and open the eye. It will be convenient to separate the muscle thus freed from the skin, beginning from the forepart of the clavicles even to the chin, ascending in a right line, and then turning back as far as you can; for thus you shall shew how it mixes it self with the skin and the muscles of the lips.

When thou shalt come to the eyes, thou shalt teach how the eye is shut and opened by this one muscle, because it is composed of the three sorts of fibers; although by the opinion of all who have hitherto written of Anatomy, those actions are said to be performed by the power of two muscles appointed for that purpose; one of which is at the greater corner on the upper part, the other resembling a semicircle at the lesser corner, from whence extending it self to the middle of the gristle *Tarsus*, it meets with the former ending there, but they are in part extended over all the eye-lid, whereby it commeth to passe that it also in some sort becomnieth movable. But although in publike dissections these two muscles are commonly wont to be solemnly shewed, after the manner I have related; yet I think, that those which shew them know no more of them than I do. I have grounded my opinion from this, that there appears no other musculous flesh in these places, to those which separate the fleshy pannicle, or broad muscle, than that which is of the pannicle it self, whether you draw your incision knife from the forehead downwards, or from the cheek upwards.

Besides, when there is occasion to make incision on the eye-browes, we are forbidden to doe it transverse, lest this broad muscle falling upon the eye, make the upper eye-lid unmoveable: but if such a cut be received accidentally, we are commanded presently to stich it up; which is a great argument that the motion of the upper eye-lid is not performed by its proper muscles, but wholly depends and is performed by the broad muscle. Now if these same proper muscles which we have described should be in the upper eye-lid, it should

There are no particular muscles appointed to open and shut the eye, for that is the work of the broad muscle only. Divers reasons to that purpose.

Why you must take heed of making a transverse incision upon the eye-browes.

be meet, (because when one of the muscles is in action, the other which is its opposite or Antagonist, rests or keeps holyday) that when that which is said to open the eye is employed, the opposite thereof resting, the upper eye-lid should be drawn towards its original, as we see it happens in convulsions: because the operation of a muscle is the collection of the part which it moves towards its original.

Therefore seeing such a motion or collection appears not any where in the eye-lid, I think it therefore manifest that all the motion of this upper eye-lid depends upon this broad muscle, and that it alone is the author of the motion thereof.

The original of this broad muscle is from the upper part of the *Sternum*, the clavicles, the shoulder blades, and all the spines of the *vertebra's* of the neck: but it is inserted into all these parts of the head which want hair, and the whole face, having divers fibers from so various an original, by benefit of which it performs such manifold motions in the face (for it so spreads it self over the face, that it covers it like a vizard) by reason of the variety of the original and the production of the divers fibers of this muscle. But I have not in the description of this muscle prosecuted those nine conditions, which in the first book of my Anatomy I required in every part, because I may seem to have sufficiently declared them in the description of the muscles of the *Epigastrium*. Wherefore hence forward you must expect nothing from me in the description of muscles besides their original, insertion, action, composition, and the designation of their vessels.

The action of a muscle.

The original of the broad muscle.

The insertion and reason why we expresse so many motions with the face.

CHAP. IV.

Of the Eye-lids and Eye-browes.

Because we have saide into mention of the eye-lids, and eye-browes, and because the order of dissection also requires it, we must tell you what they are, of what they consist, and how and for what use they were framed by nature. Therefore the eye-browes are nothing else, than a rank of hairs set in a semi-circular form upon the upper part of the orb of the eye, from the greater to the lesser corner thereof, to serve for an ornament of the body, and a defence of the eyes against the acrimony of the sweat falling from the forehead.

What the eye-browes are.

Their use.

But the eye-lids on each side two, one above and another below, are nothing else than as it were certain shuttings appointed and made to close and open the eyes when need requires, and to contain them in their orbs. Their composure is of a musculous skin, a gristle and haire set like a pale at the sides of them to preserve the eyes when they are open, chiefly against the injuries of small bodies, as motes, dust and such like. These hairs are alwaies of equall and like bignesse, implanted at the edges of the gristly part, that they might alwaies stand streight and stiffe out. They are not thick, for so they should darken the eye. The gristle in which they are fastned is encompassed with the *pericranium* stretched so far before it produce the *Conjunctiva*. It was placed there, that when any part thereof, should be drawn upwards or downwards by the force of the broad muscle or of the two proper muscles, it might follow entirely and wholly by reason of its hardnesse. They call this same gristle, especially the upper, *Tarsus*. The upper and lower eye-lid differ in nothing, but that the upper hath a more manifest motion, and the lower a more obscure: for otherwise nature should have in vain encompassed it with a musculous substance.

What the eye-lids are.

Their composure and use.

What the *Tarsus* is.

CHAP. V.

Of the Eyes.

The Eyes are the instruments of the faculty of seeing, brought thither by the visive spirit of the optick nerves, as in an aqua-duct. They are of a soft substance, of a large quantity, being bigger or lesser according to the bignesse of the body. They are seated in the head, that they might overlook the rest of the body, to perceive and shun such things as might endanger, or endamage the body; for the action of the eyes is most quick, as that which is performed in a monent, which is granted to none of the other senses. Wherefore this is the most excellent sense of them all. For by this we behold the fabrick and beauty of the heavens and earth, distinguish the infinite varieties of colours, we perceive and know the magnitude, figure, number, proportion, site, motion and rest of all bodies. The eyes have a pyramidall figure whose basis is without, but the Cone or point within at the optick nerves. Nature would have them contained in a hollow circle, that so by the profundity and solidity of the place they might be free from the incursions of bruising and hurtfull things.

What the eyes are.

Their site.

The quicknes and excellency of their action.

Figure.

They are composed of six muscles, five coats, three humours, and a most bright spirit; (of which there is a perpetual afflux from the brain) two nerves, a double vein, and one artery,

Composition.

tery,

Glandula Lachrymalis.

Fistula Lachrymalis.

Why fat is placed about the eyes.

tery, besides much fat, and lastly, a Glandule seated at the greater angle thereof, upon that large hole which on both sides goes to the nose, and that, lest that the humors falling from the brain should flow by the nose into the eyes, as we see it fares with those whole eyes perpetually weep, or water, by reason of the eating away of this glandule, whence that affect is called, the *Fistula lachrymalis*, or weeping Fistula.

But there is much fat put between the muscles of the eye, partly that the motion of the eyes might be more quick, in that slipperiness of the fat, as also that the temper and complexion of the eyes, and chiefly of their nervous parts, might be more constant and lasting, which otherwise by their continuall and perpetuall motion would be subject to excellent dryness. For nature, for the same reason hath placed Glandules flowing with a certain moisture, neer those parts which have perpetuall agitation.

C H A P. VI.

Of the Muscles, Coats and humors of the Eye.

The number, site and action of the muscles.

Here are six muscles in the eye, of which four perform the four direct motions of the eye: they arise from the bottom of the orb, and end in the midst of the eye encompassing the optick nerve. When they are all moved with one endeavour, they draw the eye inwards. But if the upper only use its action, it draws the eye upwards; if the lower, downwards; if the right, to the right side; if the left, to the left side.

The two other muscles turn the eye about; the first of which being the longer and slenderer, arises almost from the same place, from which that muscle arises, which draws the eye to the right side to the greater corner. But when it comes to the utmost part of the inner angle, where the *Glandula lachrymalis* is seated, it ends in a slender Tendon, there piercing through the middle membrane which is there, as through a ring; from whence it presently going back is spent in a right angle towards the upper part of the eye, betwixt the insertions of those two muscles, of the which one draws the eye upwards, the other directly to the outward corner, as it is observed by *Fallopius*, or rather, which I remember I have alwaies observed, they turn between the muscles which move the eye upwards, and to the inner corner.

This fifth muscle when it is drawn in towards its beginning, so draws the eye with its circular tendon, that it carries it to the greater corner.

The sixth muscle is contrary to that; for it hath its originall from the lower part of the orb at a small hole, by which a nerve of the third conjugation passes forth; and being that it is most slender, whilst it ascends transversely to the outward corner, it involves the eye so also, that it is inserted in it by a small Tendon, so that the Tendons of them both are oftentimes taken but for one. That thou mayst truly and accurately observe this anatomicall description of the eye, the eye must not be pluckt out of its orb, but rather the orb it self must be broken and separated.

For thus thou shalt certainly and plainly see the forementioned original of the muscles. For the five coats, the first which is first met with in dissection, comes from the *Pericranium*, and is extended over all the white of the eye, even to the *Iris* or Rain-bow. The duty of it is to strengthen, bind and contain the eye in its orb, wherefore it had the name *Conjunctiva*, others called it *Adnata*, or *Epiphephycos*.

The second is called the *Cornea*, because it resembles a horn in colour and consistence; this coat differs and varies from it self, for in the forepart, as far as the *Iris* goes, it is clear and perspicuous, but thick and obscure in the hind part, by reason of the diverse polishing. On the fore-part it is dense, that it may preserve and contain the Crystalline and waterish humor, but withall transparent, so to give the object a freer passage to the Crystalline. It hath its originall from the *Crassa meninx*, proceeding forth from the inner holes of the orb of the eye, for it compasses the eye on every side.

The third is called the *Vvea* or Grapy coat, because in the exterior part it represents the colour of a black grape; it arises from the *Pia mater*, and encompasses all the eye, except the *pupilla* or apple of the eye, for here being perforated, it adheres to the horny coat by the veins and arteries which it communicates to it for life and nourishment. But when it arrives at the *Iris*, then forsaking the *Cornea*, it descends deep into the eye, and in some sort is turned about the Crystalline humour, to which also it most firmly adheres, so bounding the waterish humour, and also prohibiting that the Albugineous humor do not overwhelm the Crystalline. This grapy coat is as it were dyed on the inside with divers colours, as black, brown, blew, or green like a rain-bow; and that for these ensuing benefits.

The first is, if that it had been tinctured with one colour, all objects would have appeared of the same colour, as it comes to passe when we look through green or red glasse. But it must be coloured, that so it may collect the spirits dissipated by the Sun and seeing.

to the horny. *mm* 4, 5. The impression of the grapy coat where it recedeth or departeth from the horny coat. *nn* 4, 5, 6, 7. The *pupilla* or apple of the eye. *oo* 7. The Ciliar or hairy proceses. *p* 7. The beginning of the grapy coat made of a thin membrane dilated, but *p* in the 17. figure sheweth the Ciliar proceses sprinkled through the fore part of the glassie humor. *r* 9. The bosome or depression of the glassie humor receiving the Crystalline. *s* 12, 15. The bredth of the coat of the Crystalline. *t* 12, 13, 14, 16. The posterior part of the Crystalline humor, which is sphericall or round. *u* 11, 14, 20. The fore part of the same Crystalline depressed. *x* 10, 20. The amplitude of the glassie humor. *y* 10, 16, 19. The amplitude of the watry humor. *z* 19. The place where the glassie humour is distinguished from the watry by the interposition of the *Hyaloides* or coat of the glassy humor. *a* 10, 16. The place where the grapy coat swimmeth in the watry humor. *b* 18. The cavity or depression of the glassie humor which remaineth when the Crystalline is exempted or taken from it. *d* 19. the cavity or depression of the watry humor made by the same means.

Thirdly, it was convenient it should be painted with infinite variety of colours for the preservation of the sight. For as the extreame colours corrupt and weaken the sight, so the middle refresh and preserve it, more or lesse as they are neerer, or further remote from the extremes. It was fit it should be soft, that so it might not hurt the Crystalline humor upon whose circumference it ends; and perforated in the part objected to it, lest by its obscurity it should hinder the passage of the objects to the Crystalline, but rather that it might collect by its blacknesse as a contrary, the great and as it were diffused variety of colours, no otherwise than we see the heat is strengthned, by the opposition of cold; some call this coat *Choroides*, because it is woven with many veins and arteries, like the coat *Chorion* which involves the infant in the womb.

Amphiblestroides or *Retiformis*, Net-like coat.

Now follows the fourth coat called *Amphiblestroides* or *Retiformis*, the Net-like coat, because proceeding from the optick nerve dilated into a coat, it is woven like a net with veins and arteries which it receives from the grapy coat, both for the life and nourishment both of it self, as also of the glassie humor which it encompasses on the back part. The principall commodity of this coat is, to perceive when the Crystalline humor shall be changed by objects, and to lead the visive spirit instructed or furnished with the faculty of seeing, by the mediation of the glassie humour, even to the Crystalline being the principall instrument of seeing. It is softer than any other coat, lest the touch of it should offend that humor. Wherein thou wilt admire the singular order of nature, which as in other things it passes not from one extreme to another unlesse by a *Medium*, so here it hath not fitted the hard horny coat to the soft humors, but by interposition of divers *media* of a middle consistence. For thus after the harder coats *Adnata* and *Cornea* it hath placed the grapy coat, by so much softer then these two, as the Net-like coat is softer then it, that thus it might passe from extreme to extreme as it were by these degrees of hardnes and softnes.

An Anatomical Axiome.

Arachnoides, five *Araneosa*, the Cobweb-coat.

The fifth and last coat is called *Arachnoides*, because it is of the consistence of a spiders web. And we may well resemble this coat, to that skin of an union which exceeds the other in clearnes, whiteness, and thinness. This *Araneosa* or Cobweb-like coat encompasses the Crystalline humor on the fore side, peradventure that so it might defend it, as the chief instrument of seeing, if the other humors should at any time be hurt. It hath its originall from the excrementitious humidity of the Crystalline humor, hardned into that coat by the coldnes of the adjacent part; absolutely like the thin skin which encompasses the white of an Egg.

The 3 humors of the eye.

Aqueus, or watery.

The first humor of the eye is called the *Aqueus* or waterish, from the similitude of water; it is seated between the transparent part of the horny coat, the portion of the Crystalline humor lying towards the apple of the eye; and that reflection of the grapy coat which comes from the *Iris* to the circumference of the Crystalline humor, that filling the empty space it may distend the *Cornea*, and so hinder the falling thereof upon the Crystalline which would spoil the sight; as also that by its moisture it might hinder the drying of the Crystalline humor. Peradventure it is made of the whayish humor sweating out of the vessels of the coats, having their orifices for the most part in that place, where this waterish humor resides. The second humor and middlemost in situation is called the Crystalline, because it imitates Crystall in the brightness and colour; if so be that we may attribute any colour to it. For indeed it was fit that none of the three humors should be tintured with any colour, as those which would be the instruments of sight, lest they might beguile us in seeing, as red and green spectacles do; for that is true which we have red written by the Philosopher; That the subject or matter appointed for the reception of any form should want all impression thereof. Hence nature hath created a formless matter, the humors of the eyes without colours, wax without any figure, the mind without any particular knowledg of any thing, that so they might be able to receive all manner of forms. The figure of the Crystalline humor is round, yet somewhat flatted on the fore side, but yet more flatted behind, that so the objects might be the better retained in that, as it were, plane figure, and that they might not fly back as from a Globe, or round body, in which they could make but short stay; lest it might be easily moved from its place by the force of any thing

2 *Crystallinus*, *Crystalline*.

A Philosophical Axiome.

thing falling or hitting against it, because that body which is exactly round touches not a plane body but only in a point or prick. Half this humor swims in the glassie humor, that so it may be nourished from it by transposition of matter; or rather (seeing it is encompassed on every side with the fitt coat, that the matter cannot easily be sent from the one into the other) by the benefit of the vessels produced even unto it as well by the Net-like coat as by the Grapy, but it is filled with a bright spirit on the forepart, which lyes next to the waterish humor, and the space of the Apple of the eye.

Of which thing this is an argument, that as long as a man remains alive, we see the eye every way full, and swoln, but lank and wrinkled when he is dead; besides also one of the eyes being shut, the *Pupilla* of the other is dilated by the spirit compelled to fly thither. And also for the same cause the horny coat is wrinkled in very old men, and the *Pupilla* is straitned by the wrinkles subsiding into themselves, which is the cause that they see little, or not at all; for by age and success of time the humor is consumed by little and little, the implanted spirit vanishes away, and smaller quantity of spirits flow from the brain, as from a fountain which is also exhausted. The horny coat at his original, that is, in the parts next the *Iris*, seemeth to be very nigh the Crystalline humor, because all the coats in that place mutually cohere as touching one another, but as it runs further out to the *Pupilla*, so it is further distant from the Crystalline. Which you may easily perceive by Anatomical dissection, and the operation of touching or taking away a Catarrhaet: for whereas a Catarrhaet is seated between the horny coat, and Crystalline humor, the needle thrust in, is carried about upwards, downwards, and on every side through a large and free space, neither touching the horny coat nor Crystalline humour, by reason these bodies are severed by a good distance filled with spirit and a thin humour. The use of it is, that it may be like a looking-glasse to the faculty of seeing carried thither with the visive spirit.

The third and last humor is the *Vitreus* the glassie, or rather Albugineous humor, called so, because it is like molten glasse, or the white of an Egg. It is seated in the hind part of the Crystalline humor, that so it may in some sort break the violence of the spirit flowing from the brain into the Crystalline humour, no otherwise than the watry humor is placed on the foreside of the Crystalline to hinder the violence of the light and colours entering that way. This glassie humor is nourished by the Net-like coat.

We have formerly spoken sufficiently of the nerves of the eye: Wherefore it remains that we speak of the veins. Some of these are internall, carried thither with the coats of the vessels of the brain; other some externall, stretched over the externall parts of the eye, as the Muscles, and coat *Adnata*; and by these veins inflammations and redness often happen in the externall parts of the eye: for which the *Vena pupis* must be opened, and cupping glasses and horns must be applied to the nape of the neck and shoulders: as in the internall inflammations of the eye, the cephalik vein must be opened to avert and evacuate the moribifick humor.

CHAP. VII.

Of the Nose.

THe Nose is called in Greek *Riz*, because the excrements of the Brain flow forth by this passage, thou maist understand it hath a divers substance by composition. The quantity, figure and site are sufficiently known to all. But it is composed of the skin and muscles, bones, gristles, a membrane or coat nerves, veins and arteries. The skin and bones both contained and containing, have formerly been explained, as also the nerves, veins and arteries. The gristles of the Nose are six in number; the first is double, separating both the nostrills in the top of the nose extended even to the bone *Ethmoides*. The second lyes under the former. The third and fourth are continued to the two outward bones of the nose. The fifth and sixth being very slender and descending on both sides of the nose, make the wings or moveable parts thereof. Therefore the use of these gristles is, that the nose moveable about the end thereof, should be lesse obnoxious to externall injuries, as fractures and bruises, and besides more fit for drawing the air in and expelling it forth in breathing. For nature for this purpose hath bestowed four muscles upon the nose, on each side two, one within, and another without.

The External taketh its original from the cheek, and descending obliquely from thence, and after some sort annexed to that which opens the upper lip, is terminated into the wing of the nose, which it dilates.

The internall going on the inner side from the jaw-bone, ends at the beginning of the gristles that make the wings, that so it may contract them. The coat which inwardly invests the nostrills and their passages, it produced by the five-like bones from the *Crassa meninx*, as the inner coat of the palat, throttle, weazon, gullet and inner ventricle, that it is no marvel, if the affects of such parts be quickly communicated with the brain. This same coat on each side receives a portion of a nerve from the third

The Gristles of the nose.

The muscles thereof.

The temper,
action and use.

conjugation, through the hole which descends to the nose by the great corner of the eye. The nose in all the parts thereof is of a cold and dry temper. The Action and profit thereof is to carry the air and oft-times smells to the mamillary processes, and from thence to the four ventricles of the brain, for the reasons formerly shewed. But because the mamillary processes being the passages of the air and smells are double, and for that one of these may be obstructed without the other, therefore nature hath also distinguished the passage of the nose with a gristly partition put between, that when the one is obstructed, the air by the other may enter into the brain for the generation and preservation of the animall spirit. The two holes of the nose first ascend upwards, and then downwards into the mouth, by a crooked passage, lest the cold air, or dust should be carried into the lungs. But the nose was parted into two passages as we see, not only for the forementioned cause, but also for helping the respiration and vindicating the smell from externall injuries; and lastly, for the ornament of the face.

Why the nose
was parted in
two.

CHAP. VIII.

Of the Muscles of the Face.

Their number.

Now we must describe the muscles of the face pertaining as well to the lips as to the lower jaw. These are 18. in number, on each side nine, that is, four of the lips, two of the upper, and as many of the lower. But there belong five to the lower jaw. The first of the upper lip being the longer, and narrower, arising from the yoke-bone descends by the corner of the mouth to the lower lip, that so it may bring it to the upper lip, and by that means shut the mouth. The other being shorter and broader, passing forth of the hollownes of the cheek, or upper jaw (by which a portion of the nerves of the third conjugation descends to these two muscles, and other parts of the face) ends in the upper part of the same upper lip, which it composes together with the fleshy pannicle and skin, and it opens it by turning up the exterior fibers towards the nose, and shuts it by drawing the internall inwards towards the teeth.

The first of the lower lip being the longer and slenderer, entering out of that region which is between the externall perforation of the upper jaw (through which on the inner part of the same, a nerve passeth forth to the same muscles) and the muscle *Masseter*, (of which hereafter) then ascending upwards by the corner of the the mouth, it ends in the upper lip, that so it may draw it to the lower.

The other broader and shorter begins at the lower part of the chin, and the hollownes thereof, and ends at the lower lip which it makes, opening it within and without by its internall and externall fibers, as we also said of its opposite. And that I may speak in a word, nature hath framed three sorts of muscles for the motion of the mouth, of which some open the mouth, others shut it, and othersome wrest it and draw it awry; but you must note that when the muscles of one kind jointly perform their functions (as the two upper which we described in the first place, on each side one, which draw the lower lip to the upper, and the muscles opposite to them) they make a right or streight motion; but when either of them moves severally, it moves obliquely, as when we draw our mouth aside. But these muscles are so fastned and fixed to the skin, that they cannot be separated; so that it is no great matter whether you call it a musculous skin, or a skinny muscle: (Which also takes place in the palms of the hands and soles of the feet) but these muscles move the lips the upper jaw being not moved at all.

CHAP. IX.

Of the Muscles of the lower Jaw.

Their number.

The Tempo-
rall muscle.

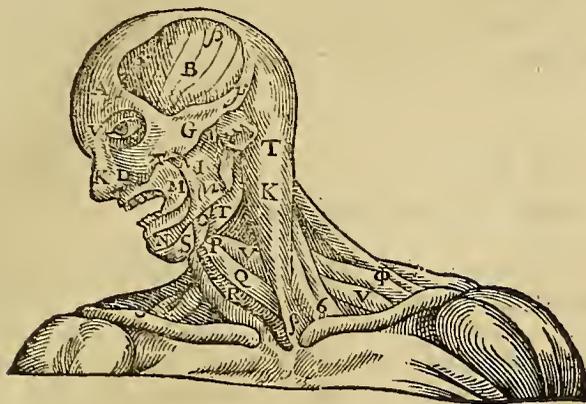

WE have said these muscles are five in number, that is, four which shut it, and one which opens it, and these are alike on both sides. The first and greater of these four muscles which shut the Jaw is called *Crotophita* or Temporall muscle; it arises from the sides of the forehead and *Bregma* bones, and adhering to the same and the stony bone, it descends under the yoke-bone, from whence it inserts it self to the proesse of the lower jaw which the Greeks call *Corone*, that it may draw it directly to the upper, so to shut the mouth.

Why the
wounds of the
temporall
Muscle are
deadly.

But you must note, that this muscle is tendinous even to his belly, and that it fills and makes both the temples. It is more subject to deadly wounds than the rest by reason of the multitude of nerves dispersed over the substance thereof, which because they are near their originall, that is, the brain, they infer danger of sodain death by a convulsion which usually follows the affects of this muscle, but also in like manner it causes a Fever, the Phrensy and *Coma*.

The figure of the chief muscles of the Face.

FIG. II.

- G. The yoaik-bone under which the temporall muscles passe.
- l. The Masseter, or Grinding muscle:
- K. The upper gristle of the nose.
- M. A muscle forming the cheeks:
- N. The muscle of the lower lip.
- O. A part of the fifth muscle of the lower Jaw called Digastricus, that is, double bellied.
- Q. R. The first muscle of the bone Hyoides growing unto the rough Artery.

- S. The second muscle of the bone Hyoides under the Chin.
- T. The third muscle of the bone Hyoides stretched to the Jaw.
- T. K. The seventh muscle of the head and his insertion at T.
- V. V. The two venters of the fourth muscle of the bone Hyoides.

φ. The place where the vessels passe which go to the head, and the nerves which are sent to the Arm.

Therefore that it should be lesse subject or obvious to externall injuries, Nature hath, as it were, made it a retiring place in the bone, and fortified it with a wall of bone raised somewhat higher about it. The other Muscle almost equall to the former in bigness, being called the *Masseter*, or grinding muscle, makes the Cheek; it descends from the lowest part of the greatest bone of the orb (which bends it self as it were back, that it may make part of the yoaik-bone) and inserts it self into the lower Jaw, from the corner thereof to the end of the root of the proceffe *Corone*, that so it may draw this Jaw forward and backward, and move it like a hand-mill.

The *Masseter* or grinding muscle.

Wherefore nature hath composed it of two sorts of fibers, of the which some from the neck (the cheek in that place under the eyes standing somewhat out like an apple arising from the concurrence of the greater bones of the orb and upper jaw) descend obliquely to the corner and hinder part of the lower jaw, that it may move it forwards. Other some arise from the lower part of the same yoaik-bone, and descending obliquely intersect the former fibers after the similitude of the letter X, and insert themselves into the same lower jaw at the roots of the proceffe *Corone*, that so they may draw it back: Truly by reason of these contrary motions it is likely this muscle was called the *Masseter* or grinder.

The third, which is the round muscle, arises from all the Gums of the upper jaw, and is inserted into all the gums of the lower, investing the sides of all the mouth with the coat, with which it is covered on the inside, being otherwise covered on the outside with more fat than any other muscle. The action thereof is, not only to draw the lower Jaw to the upper, but also as with a shovell to bring the meat dispersed over all the mouth under the teeth, no otherwise then the tongue draws it in.

The round muscle.

The fourth being shorter and lesse than the rest arising from all the hollowness of the winged proceffe of the *Wedge-bone*, is inserted within into the broadest part of the lower Jaw, that so in like manner it may draw the same to the upper. This is the muscle through whose occasion, we said this lower Jaw is sometimes dislocated.

The lesser muscle of the lower Jaw.

The fifth and last muscle.

The use of these mentioned muscles.

to draw this Jaw downwards from the upper in opening the mouth. This muscle is slender and tendinous in the midst, that so it might be the stronger, but it is fleshy at the ends. All these muscles were made by the singular providence of nature, and engrafted into this part for the performance of many uses and actions, as biting asunder, chewing, grinding and severing the meat into small particles, which the tongue by a various and harmless motion puts under the teeth. Thus much I thought good to say of the parts of the face, as well containing as contained.

CHAP. X.

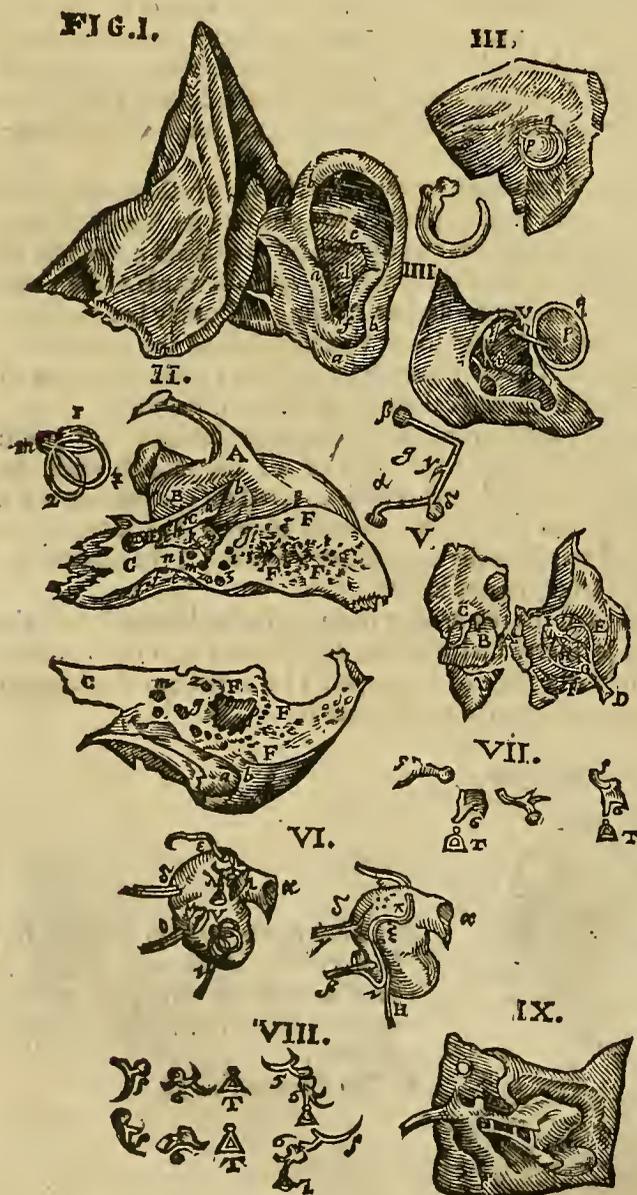

Of the Ears and Parotides or kernels of the Ears.

The nature and composition of the ears. What the Fibra and pinna are. The figure and the reason thereof.

The Ears are the Organs of the sense of hearing. They are composed of the skin, a little flesh, a gristle, veins, arteries and nerves. They may be bended or folded in without harm, because being gristly, they easily yeeld and give way; but they would not do so, if they should be bony, but would rather break. That lap at which they hang pendants and Jewels, is by the ancients called *Fibra*, but the upper part *pinna*. They have been framed by the providence of nature into two twining passages like a Snails shell, which as they come neerer to the *foramen cecum* or blind hole, are the more straitned, that so they might the better gather the air into them, and conceive the differences of sounds and voices, and by little and little lead them to the membrane.

The Figure of the ears and bones of the auditory passage.

Tab. 10. sheweth the ears and the divers internall parts thereof.

Fig. 1. sheweth the whole externall ear, with a part of the Temple bone.

Fig. 2. sheweth the left bone of the Temple divided in the midst by the instrument of hearing, whereabout on either side there are certain passages here particularly described.

Fig. 3, and 4. sheweth the three little Bones.

Fig. 5. sheweth a portion of the bone of the temples which is seen neer the hole of Hearing divided through the midst, whereby the Nerves, Bones and Membranes may appear, as Vesalius of them conceiveth.

Fig. 6. sheweth the Vessels, Membranes, Bones and holes of the Organ of hearing, as Platerus hath described them.

Fig. 7, and 8. sheweth the little bones of the hearing of a man and of a Calfe, both joined and separated.

Fig. 9. sheweth the Muscle found out by Aquapendens.

For the particular declaration see D. Crooks Anatomy. pag. 577.

This membrane which is indifferently hard hath grown up from the nerves of the fifth

fifth conjugation, which they call the auditory. But they were made thus into crooked windings, lest the sounds rushing in too violently should hurt the sense of hearing. Yet for all this we oft find it troubled and hurt by the noise of thunder, Guns and Bels. Otherwise also lest that the air too sodainly entring in should by its qualities, as cold, cause some harm: and also that little creeping things and other extraneous bodies, as fleas and the like, should be stayed in these windings and turnings of the waies, the glutinous thickness of the cholerick excrement or ear-wax hereunto also conducing, which the brain purges and sends forth into this part, that is, the auditory passage framed into these intricate Mæanders.

But that we may understand how the hearing is made, we must know the structure of the organ or instrument hereof. The membrane which we formerly mentioned to consist of the auditory nerve, is stretched in the inside over the auditory passage like as the head of a Drum. For it is stretched and extended with the air, or auditory spirit implanted there, and shut up in the cavity of the mamillary proceſſe and *foramen cæcum*, that smitten upon by the touch of the externall air entring in, it may receive the object, that is, the sound, which is nothing else then a certain quality arising from the air beaten or moved by the collision and conflict of one or more bodies.

Such a collision is spread over the air, as the water which by the gliding touch of a stone produces many circles and rings one as it were rising from another. So in rivelets running in a narrow channel, the water stricken, and as it were, beaten back in its course against broken, craggy and steep rocks, wheels about into many turnings: this collision of the beaten air flying back divers waies from arched and hollow roofed places, as Dens, Cisterns, Wells, thick Woods and the like, yeelds and produces a double sound, and this reduplication is called an Echo. Wherefore the hearing is thus made by the air, as a medium, but this air is twofold, that is, externall and internall.

The exterior is that which encompasses us, but the interior is that which is shut up in the cavity of the mamillary proceſſe and *foramen cæcum*, which truly is not pure and sole air, but tempered and mixed with the auditory spirit. Thence proceeds the noise or beating of the ears, when vapors are there mixed with the air instead of spirits, whereby their motion is perturbed and confused. But neither do these suffice for hearing, for nature for the more exact distinction of sounds hath also made the little bones, of which one is called the *Incus* or anvil, another the *Malleolus* or hammer, the third the *Stapes* or stirrop, because the shape thereof resembles a German stirrop. Also it may be called *Deltoides*, because it is made in the shape of the Greek letter Δ.

They are placed behind the membrane, wherefore the anvil and hammer moved by the force of the entrance of the externall air, and beating thereof against that membrane, they more distinctly expresse the difference of sounds, as strings stretched within under the head of a Drum; as for example, these bones being more gently moved represent a low sound to the common sense and faculty of hearing, but being moved more vehemently and violently, they present a quick and great sound; to conclude, according to their divers agitation, they produce divers and different sounds.

The Glandules should follow the Ears in the order of Anatomy, as well those which are called the emunctories of the brain, that is, the *Parotides*, (which are placed as it were at the lower part of the ears) as these which lye under the lower Jaw, the muscles of the bone *Hyoides* and the tongue, in which the *Scrophulæ* and other such cold abscesses breed. It shall here suffice to set down the use of all such like Glandules.

Therefore the *Parotides* are framed in that place by nature, to receive the virulent and malign matter sent forth by the strength of the brain, by the veins and arteries spread over that place. The rest serve to strengthen the division of the vessels, to moisten the ligaments and membranes of the Jaw, lest they should be dried by their continuall motion. Their other conditions and uses are formerly handled in our first book of Anatomy.

CHAP. XI.

Of the bone Hyoides, and the Muscles thereof.

The substance of the bone *Hyoides* is the same with that of other bones. The figure thereof imitates the greek letter υ from whence it took the name, (as also the name υμυλοειδης; and from the letter λ it is in like sort called λυμβοειδης; by some it is stiled *os Gutturis* and *os Linguae*, that is, the Throat-bone and Tongue bone. The composition thereof consists of many bones joined into one by the interposition of gristles.

This bone is bigger in beasts and composed of more bones, and that not only by the intercourse of gristles, but also of ligaments. It is seated with its basis (being gibbous on the

forepart for constancy, and arched on the inside that it might receive and contain the root of the tongue) upon the upper part of that gristle of the throtle which is called *scutiformis* or Shield-like, (for this seems to prop it up by the strength of two processes rising at the basis thereof) and the root of the tongue. From this basis it sends forth two horns to the sides of the tongue on each side one, which in men are tyed to the Appendix *styloides* by ligaments sent from it self. Contrary then it is in beasts, who have it of many bones united as we said, by the intercourse of ligaments even to the root of the *styloides*. Wherefore this bone hath connexion with the forementioned parts, and other hereafter to be mentioned. It hath the same temper as other bones have. The use of it is, to minister ligaments to certain muscles of the tongue, and insertion as well to the two foremost and upper muscles of the throtle, as to its own, of which we will now treat.

The temper and use.

The muscles of the bone *Hyoides*.

The muscles of the bone *Hyoides*, according to the opinion of some are eight, on each side four; of which there be two, one of which *Galen* refers to the common muscles of the *larinx* or throtle; and the other to those which move the shoulder-blade upwards. Howsoever it be, the first of the four before mentioned arises from the Appendix *Styloides*, and passing over the nervous substance of the muscle opening the lower jaw, is inserted into the horns of the bone *Hyoides*. This muscle is very thin, yet somewhat broad, the which in that respect may easily be cut, unless you have a care in separating the muscle which opens the lower Chap. The second ascends obliquely from the upper part of the shoulder-blade near the production thereof called *Coracoides*, to the beginnings of the horns of the said bone *Hyoides*. This is round and nervous in the midst that so it might be the stronger, as that is which we formerly said opens the lower jaw; and it is refer'd by *Galen* amongst those which move the shoulder-blade upwards. The third arises from the upper part of the *sternon*, and is inserted at the root and basis of the bone *Hyoides*; yet *Galen* refers it to the common muscles of the *Larinx*; whose opinion takes place rather in beasts, than in man, seeing in man this muscle cannot be found either to proceed, or be inserted into the throtle, as it is in beasts. The fourth and last descends within from the chin to the root of the bone *Hyoides*. The first of these muscles with its companion or partner moves the bone *Hyoides* upwards, the second downwards; the third backwards; and the fourth forwards. I would declare whence these muscles have their vessels, had I not abundantly satisfied that thing, when I treated of the distribution of the nerves, veins and arteries.

The action of these muscles.

CHAP. XII.

Of the Tongue.

What kind of flesh the tongue hath.

THE tongue is of a fleshy, rare, loose and soft substance; it enjoys flesh of a different kind from the rest of the flesh, as chiefly appears when you cut it from the first original of the muscles thereof; which thing hath moved some, that they have made a fourth kind of flesh proper to the tongue and different from the rest, viz. the fibrous, musculous, and that of the bowells. The quantity thereof is such that it may be contained in the mouth, and easily moved to each part thereof. The figure of it is triangular, which it rather expresses in the basis, which is at the root of the bone *Hyoides*, than in its point, or forepart, where from a triangle it becomes more dilated. It is composed of a membrane (which it hath from that which lines all the inside of the mouth) muscles 4. nerves two on each side, the one whereof is sent from the third conjugation, into the coat thereof; the other from the seventh is sent into the musculous substance even to the end thereof for motions sake; so that those sensifick nerves from the third conjugation only give to judg of tastes, compose the coat, and touch or enter not the flesh. Besides it is composed of veins and arteries on each side one, which it receives from the externall *Jugular* and *Carotides*, running manifestly to the end thereof on the lower side, that so they might be easily opened in the diseases of the mouth and throtle; they commonly term these the *Vene nigrae* or black veins.

The quantity. The figure.

Composure. The nerves.

The muscles of the tongue.

The muscles of the tongue, are absolutely ten, on each side five. The first narrow at the beginning and broader at the end, descends into the upper side of the tongue from the Appendix *Styloides*, and together with its copartner draws it upwards. The second hath its original within from the lower jaw, about the region of the grinding-teeth, and is inserted into the lower side of the tongue, the which with its partner draws it downward. The third proceeds from the inner part of the chin, and goes to the root of the tongue, that when need requires it may put it forth of the mouth. The fourth the greatest and broadest of them all, composed of all sorts of fibers, passes forth from the basis of the bone *Hyoides*, and ends at the lower part of the tongue, which with its companion plucks it back into the mouth. The fifth and last most usually arises from the upper part of the horns of the bone *Hyoides*, and goes to the roots of the tongue between the two first, that it may move it to the sides of the mouth.

mouth. The temper thereof, as of all other flesh, is hot and moist. The first action and commodity thereof is, to be the organ of the sense of tasting, wherefore it was made fungous and spongy, that by reason of the rarity of it, it might more easily admit the taste conjoined with the spittle, as a vehicle. Another to be an instrument to distinguish the voice by articulate speech, for which it was made movable into each part of the mouth. The third is to be a help to chew and swallow the meat. For which cause it is like a scoop or dish with which we throw back the corn into the mill, which hath escaped grinding. And because, when the tongue is dry, it is less nimble and quick to perform its motions, as appears by those which can scarce speak by reason of thirst or a burning Feaver: therefore nature hath placed very spongy glandules at the roots thereof, on each side one, which like sponges suck and receive, both from the brain and other places, a waterish and spittlely humor, with which they humect and make more glib, not only the tongue, but also the other parts of the mouth, as the throat and jawes; these glandules are called the *Tonsille*, or Almonds of the throat.

The temper, action, and manifold use of the tongue.

The use of the glandules placed at the roots of the tongue.

CHAP. III.

Of the Mouth.

The mouth is that capacity which bounded with the cheeks and lips contains within its precincts the teeth, tongue, and the beginnings of the throat and gullet. Therefore the use of the mouth is to contain the tongue, and serve it in the fitter performance of its actions; and although many parts hereof have been formerly handled, as the lips, teeth, jawes, tongue, almonds, and passages of the palat coming from the nose, yet it remains, that we declare what the palat, the *Gargareon*, or *Vvulva*, the *Pharinx*, and *fauces* or Chops are. The Palat (or as it is commonly called, the Roof of the mouth) is nothing else but the upper part of the mouth bounded with the teeth gums and upper Jaw. In which place the coat common to the whole mouth, is made rough with divers wrinkles, that the meats put up and down between the tongue and the Palat might be broken and chewed more easily by that inequality and roughness. If any would find the nerves, which descend into the palat from the fourth conjugation, let him separate that coat and cast it from the fore to the hind part of the mouth; for so he shall find them at the sides and hind parts of the bones of the Palat, which incompass the Palat, and at the beginning of the inner holes of the mouth, which descend from the nose, and region of the productions of the wedgbone called the Saddle. These holes or passages are open, that we may breath the better when we sleep, and that when the nose is not well, the excrements which seek their passage by it, may be easilier drawn away by the mouth. This same coat is woven with nervous fibers, that like the tongue it might judg of taste; these fibers compose a coat that hath a middle consistence betwixt soft and hard. For if it should have been any harder, like a bone or gristle, it would have been without sense, but if softer, hard, acrid and sharp meats would have hurt it.

What it is.

The use.

What the palat is.

The nerves thereof.

Why the holes of the palat are open.

What kind of coat the palat hath.

CHAP. XIII.

Of the Gargareon, or Vvulva.

By the *Gargareon* we understand a fleshy and spongy body, in shape like a pine apple, hanging directly down at the further end of the palat and basis of the bone *Ethmoides*, where the two holes of the palat come from the nose, above the entrance of the throtle. This little body is situate in this place to break the violence of the air drawn in by breathing, and that by delay it might in some sort temper and mitigate it by the warmth of the mouth. Besides, that it might be as it were the *Pleurum*, or quil of the voice, so to diffuse the fuliginous vapour sent forth in breathing, that it may be dispersed over all the mouth, that resounding from thence it may be articulate, and by the motion of the tongue distinguished and formed into a certain voice. Which use is not small, when we see by experience that such as have this particle cut away, or eaten, or corrupted by any accident, have not only their voyce vitiated and depraved, but speak ill-favouredly, and as they say, through the nose; and besides in process of time they fall into a consumption by reason of the cold air passing down before it be qualified. This same particle, is also a means to hinder the dust from flying down through the weazon into the Lungs. By the *Pharinx* and *fauces* is meant the inner and back part of the mouth, set or placed before the entrance of the Throtle and Gullet; being so called, because that place is narrow and strait, that as it were by these straits, the air drawn in by the mouth might be forced down by the Throtle, and the meat into the Gullet.

What the *Gargareon*, or *Vvulva* is.

The site and manifold use thereof.

The discomforts that ensue the loss of the *Vvulva*.

What the *Pharinx* and *fauces* are.

CHAP. XV.

Of the Larinx, or Throttle.

What is meant
by the *Larinx*.

First we must shew what is meant by the *Larinx* and Throttle, then prosecute the other conditions of it after our accustomed manner. Therefore by the *Larinx* we understand nothing else in this place, than the head & extremity of the rough artery, or weazon, which comes neerer to gristly substance, than to any other. The quantity thereof is sufficiently large, yet divers according to the diversity of bodies. It resembles in shape the head of a *Germane* pipe. The composition of it consists of 18. muscles, on each side nine, which as they are like in quantity, so also in strength and action; of three gristles, veins, arteries and nerves, as we shewed, when we spoke of the distribution of the vessels; as also of a double coat, the one externall, the other internall, as we shewed when we spoke of the weazon. These three gristles are joyned together by certain Ligaments and muscles; the foremost gristle, which also is the greater, is called by the Greeks *βυρροειδής*, in Latin commonly *Scutiformis*, that is shield-like, because it resembles a shield. The second being the hinder and middle in magnitude, wants a name, wherefore it is called the *innominata* or nameless gristle. The last and least, which notwithstanding may be parted into two, so lyes upon the edges of the other, that it resembles the mouth of an oyl pot, or a pitcher, whereupon the Greeks call it *Arytenoides*. These gristles thus fitted amongst themselves utter a distinct voice, by the benefit of the *Epiglottis*, or After-tongue; and also of the muscles opening and shutting, dilating and compressing them, whence proceed infinite varieties of voices. For thus when they are opened and dilated, they yeeld a heavy, or dull sound; when they are shut or drawn together, a quick, or sharp sound; and to conclude, they make it infinite wayes different according to the infinite variety of the dilatation, or constriction thereof. Therefore because it was fit these gristles should be moveable, especially the *Arytenoides*, and *Thyroides*, nature hath put to them on each side 9 muscles, of which three are common, and six proper. The first of the common lying hid under the third muscle of them that move the bone *Hyoides*, arises from the root of the same bone, and by an oblique descent inserts it self at the basis of the shield-like gristle, to dilate it upwards and downwards. The second ascends obliquely from the inner part of the *sternon* according to the length of the weazon (whence it is called *Bronchius*) to the bottom and sides of the same shield-like gristle, that it may open and dilate it with its wings. This muscle is seen from the first original thereof, even a great part of the way straitly to cohere with the third muscle of the bone *Hyoides*; therefore under each of the muscles, there is a glandulous body spread about the fore and upper part of the weazon, on that place where it applies it self to the throttle; this body although it resemble a fleshy substance, yet it is a glandule, which being pluckt away by a certain Emperick taking upon him to cure the kings evill, caused a defect of voice on one side, because he pulled away the recurrent nerve lying upon the glandule as it goes to the throttle, as *Galen* reports, *Lib. de locis affectis*. The third and last arises from the parts of the *Vertebra's* of the neck lying transversly upon the sides of the gullet, and ends at the wings and sides of the shield-like gristle, that it may tye it more straitly to the second gristle. But these three are called common muscles, because they take their original from some other place than the throttle, that so they may be inserted into some part thereof; for they are called the proper muscles which arise from the Throttle it self, which we have said to be six on each side: the first of which arising from the fore part of the second gristle, makes a circle under the basis of the shieldlike gristle; whilst ascending obliquely to the basis thereof, it is afterwards inserted in a part of it, so to strengthen and dilate it. The second in like manner arising from the second gristle, from that place where it adheres to the first, it runs obliquely crossing the first to the inner and forepart of the gristle *Thyroides* neer to the basis thereof, that it may joyn it to the second. The third from the hind basis of the second gristle ascends directly to the basis of the third gristle *Arytenoides*, that with the second muscle it may open and shut it. The fourth ascends from the sides of the second gristle, neer the originall of the second muscle, to the sides of the *Arytenoides*, that with the second muscle it may open and shut it. The fifth arises from the inner middle of the shield-gristle, and ends in the fore-part of the *Arytenoides* at the insertion of the fourth muscle, that so it may press down the said gristle.

ceed.

The muscles of
the *Larinx*.
Their number.

A notable
history.

And

Whence the
muscles of the
Throttle have
their nerves.

The sixth and last ascends by the hind basis of the *Arytenoides* to the fore basis of the same, to press it down. But you must note, that all such muscles as arise from below upwards, receive branches from the recurrent, but especially those who open and shut the gristle *Arytenoides*. But the site, temper, connexion, and use of the throttle may easily be known by that we have said before: Although it be a thing very full of difficulty to search out and demonstrate all the conditions of the organically parts, by reason of the diversity of their composition. Wherefore hence-forward concerning the substance, temper, and other circumstances of such parts as we shall omit, you may have recourse to those things which we have written in the Demonstration of the simple and similar parts, of which these organically

nicall are compos'd; as if any should ask of what temper the *Larinx* is, you shall answer, of a cold, dry, and hot, and moist, because it consists both of a gristly and fleshy substance. He which reckons up all the parts of the mouth, must not omit that gristly and membranous body which arises from the roots of the tongue, which that it might be more quick for motion, that is, whereby it might be more easily erected and depressed (for those things which are more soft do continually slide away, but those which are too hard cannot be bended) it was convenient it should be neither too hard nor too soft, that it might be erected whilst we breath, but depressed when we swallow. It is a principall instrument of the voice, for it cannot be well articulated unless the way were strait. Therefore it straitens that way, and the passage of the gristles of the throttle, but specially the *Arytenoides*; it is alwayes moist by a certain native, and inbred humidity; wherefore if it happen to be dried by a fever, or any other like accident, the speech is taken away. It is bound on both sides by the common membrane of the mouth to the sides of the *Arytenoides* even to the back part thereof, that so like a cover it may open and shut the orifice of the throttle, that none of the meat and drink in swallowing may fall into the weazon, in such abundance as may hinder the egress and regress of the air. For we most not think that this body doth so closely shut the orifice of the throttle, but that some small quantity of moisture alwayes runs down by the inner sides, as the walls thereof, to moisten the lungs; otherwise *Eclagma's* should be of no use in the diseases of the Chest. And because that this little body is partaker of voluntary motion, therefore according to the opinion of some there are four muscles bestowed upon it, two which may open it and two that shut it, on each side one. The opening muscles descend from the root of the bone *Hyoides*, and in their infertion growing into one they are terminated in the root of this body, that is, the *Epiglottis* in the back part thereof. The shutting muscles (in those creatures where they are found) arise on the inside between the coat and gristle thereof. Truly I could never observe and find these four muscles in a man, though I have diligently and earnestly sought for them, but I have alwayes observed them in beasts. Therefore some have boldly affirmed that this little body in swallowing lies not upon the orifice of the Throttle, unless when it is pressed down by the heaviness of such things as are to be swallowed; but that at all other times by reason of the continuall breathing it stands upright, the Throttle being open. There remain as yet to be considered, two small bosomes, or cavities, or rather fissures, which nature hath hollowed in the very throttle under the *Epiglottis*, on each side one, that if by chance any of the meat or drink should fall, or slip aside in the *Larinx*, it might be there stayed and retained. Beside that, the Air too violently entring, should be in some sort broken by these clefts, or chinks, no otherwise then the blood and spirit entring into the heart through the *Auricula* or Ears thereof.

The *Epiglottis*, or After-tongue.

CHAP. XVI.

Of the Neck and the parts thereof.

First we will define what the Neck is, then prosecute the parts thereof as well proper, as common, especially those of which we have not as yet treated. For it were superfluous to speak any more of the skin, the fleshy pannicle, the veins, arteries, nerves, gullet, weazon and muscles ascending and descending to the parts into which they are inserted amongst the neck; wherefore you must not expect that we should say any thing of the neck, more than to describe the *Vertebra* or rack bones, being the proper parts thereof, and the ligaments as well those proper to the neck, as those which it hath in common with the head; and lastly the muscles as well those it hath in common with the head and chest, as those of its own. Therefore the neck is nothing else, then a part of the head, which is contained between the nawl bone and the first *vertebra* of the back. First in the neck the *Vertebra's* must be considered, and we must shew what they have proper and peculiar, and what common amongst themselves, that we may the more easily shew the originall and infertion of the muscles growing out of them and ending in them. The neck consists of seven *Vertebrae* or Rack-bones, in which you must consider their proper body; and then the holes by which the spinall marrow passes; thirdly the *Apochyfes* or processes of the *Vertebrae*; fourthly the holes through which the nerves are disseminated into other parts from the spinall marrow, and besides the perforations of the transverse productions by which the veins, and arteries, which we call *Cervicales*, ascend amongst the neck, and lastly the connexion of these same *vertebrae* or Rack-bones. For the first, by the body of the *vertebra*, we understand the forepart thereof upon which the gullet lies. For the hole, that is not alwayes the largest in those *vertebrae* which are nighest the head; but it is alwayes encompassed with the body of the *vertebrae*, and besides with three sorts of processes, except in the first Rack-bone, that is right, transverse and oblique. By right we understand these extuberancies in the rack-bones of the neck which are hollowed directly in the upper part of them, and rise up crested on each side to sustain and receive the basis of the Rack-bone which is set upon it. By the oblique processes we understand the bunchings out

What the neck is.

What to be considered in the *vertebrae* of the neck.

Which be the right processes of the *vertebrae*. Which the oblique.

Which the transverse.

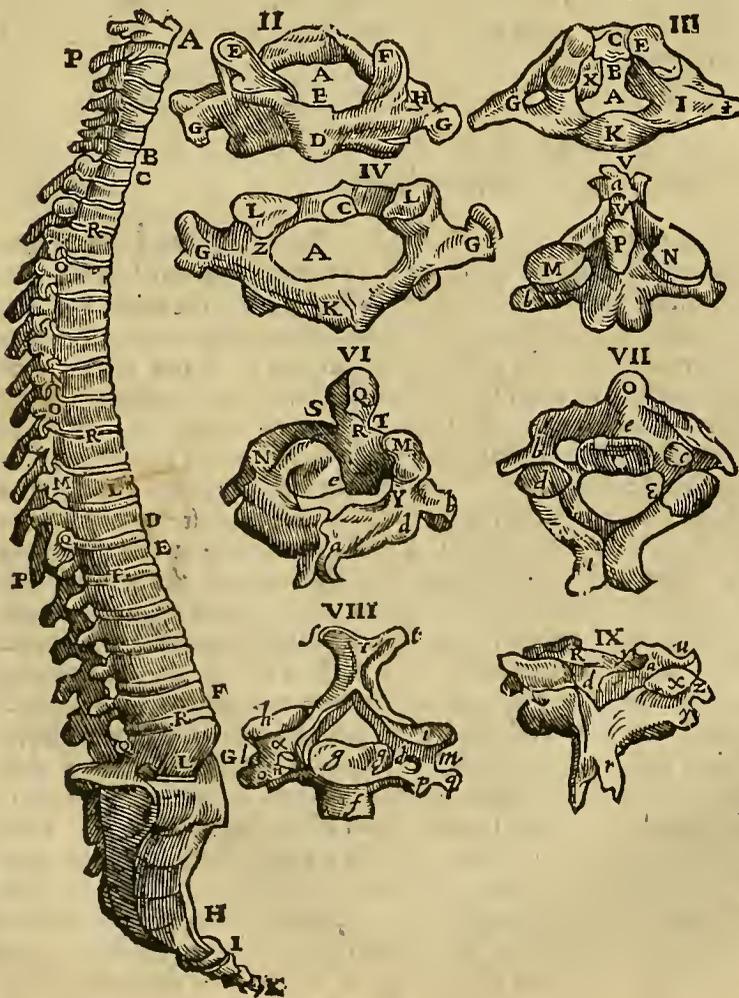

The connexions of the vertebra of the neck.

The process called the tooth.

out by which these Rack-bones are mutually knit together by *Ginglymos*; these are seated between the right and transverse processes. By the transverse we understand the protuberations next the body, which divide the *vertebra* or Rack-bone in a straight line. These processes are perforated that they may give way to the before described veins and arteries, which entering the Spinal marrow by the holes of the nerves nourish the Rack-bones and parts belonging to them. Besides you must note that the perforations of the Rack-bones of the neck, by which the nerves proceed from the spinal marrow to the outward parts, are under the transverse process, that is growing or made by the upper and lower *vertebra*, contrary to all the other which are in the rest of the Rack-bones. For the connexion of the Rack-bones, you must know that all the *vertebrae* of the spine have six connexions, two in their own bodies, & four in their oblique processes. By the two first connexions they are so mutually articulated in their own bodies that each are joyned with other both above and below. But by the four other by their oblique ascendent & descendent processes on each side two, they are so mutually inarticulate, that as the fourth Rack-bone of the neck by its oblique ascendent processes, is received of the descendent processes of the third rack-bone; so it receives the oblique ascendent processes of the first, by its oblique descendent, for alwayes the oblique ascendents are received, and the descendents receive. Yet we must except the first Rack-bone of the neck which is contained with four connexions by his lower oblique processes, and by its upper by which it receives the oblique processes both of the nowl-bone, and of the second Rack-bone. The second *vertebra* or Rack-bone must also be excepted which is holden by five connexions, that is to say, four by its oblique processes, and the fifth by its own body, by which it is knit to the body of the third *vertebra*. But we must note, that whereas nature hath not given a Spine to the first Rack-bone, yet it hath given it a certain bunch or extuberancy in stead thereof; in like manner, seeing it makes no common passage with the second *Vertebra* for the passing forth of the nerve, it is perforated at the sides of its body, and it is made very thin on the fore side, as if it were without body, that it might receive the fore process raised in the upper body of the second Rack-bone, which *Hippocrates* calls the tooth, to which the principall Ligament of the head is fastened, which descends within from the hind part of the head under the *Apophyses clinoides* or processes of the wedg-bone.

Table 20. Figure 1. Sheweth all the Rack-bones of the back knit together. Figure 2. Sheweth the fore and upper face of the neck, &c. See D. Crook, pag. 398.

FIG. I

From A, to B, the seven *vertebrae* of the neck.
 From C, to D, the twelve *vertebrae* of the chest.
 From E, to F, the five rack-bones of the Loines.
 From G, to H, the *Os sacrum*, or Holy-bone consisting, commonly of 6. *vertebrae*.
 From I, to K, the bone *Coccyx* or the rump-bone according to the late writers.
 LL, the bodies of the *vertebrae*.
 M, the transverse processes of the *vertebrae*.
 N, the descendent processes.
 OO, the ascendent processes.
 PP, the backward processes.
 QQ, the holes that are in the sides of the *vertebrae* through which the nerves are transmitted.
 RR, A gistly Ligament betwixt the *vertebrae*.
 A, 2, 3, 4, the hole whereout the marrow of the back issueth.
 B, 2, 3, The cavity which admiteth the root of the second rack-bone.
 C, 3, 4, a cavity or *Sinus* in the same place crusted over with a gristle.
 D, 2, a prominence in the outward region of this *Sinus*.
 EF, 2, 3, the *Sinus* or cavity of the first rack-bone which admiteth the 2. heads of the nowl-bone.
 GG, 2, 3, 4, the transverse process of the 1. *Vertebra*.
 H, 1, the hole of this transverse process.

L, 3, the *Sinus* which together with the cavity of the nowl-bone marked with E, maketh a common passage prepared for the nerves.

K, 3, 4, a rough place where the spine of the first rack is wanting.

LL, 4, two cavities of the first rack receiving the 2. bunches of the second rack marked with MN.

MN, 5, 6, the 2. bunches of the second rack which fall into the cavities of the first. O, 7, the appendix or root of the second rack. P, 5, a knob of this appendix crusted over with a gristle. Q, 6, the backside of the tooth.

R, 6, the *Sinus* or cavity of the same, about which a transverse Ligament is rowled containing the said tooth in the cavity of the first rack. ST, 6, Certain cavities at the sides of the tooth whence the roots issue of the fore-branch of the second pair of sinews. V, 5, the point of the tooth. X, 3, an asperity or roughness where is a hole but not thrilled through. Y, 6, a cavity of the second rack which together with the cavity marked with Z, maketh a hole through which the nerves do issue. Z, 4, the *Sinus* of the first rack. a, 5, 6, 7, the double spine of the second rack. b, 5, 6, 7, the transverse process of the second rack. c, 7, the hole of the said transverse process. d, 6, 7, the descending process of the second rack whose cavity is marked with d, in the 6. figure. e, 6, 7, the place where the body of the second rack descendeth downward. f, gg, 8, the lower side of the body of the third rack at f, the two eminent parts of the same at gg. h i, 8, the ascending processes. Im, 8, the two descending processes. n o p q, 8, the transverse processes. r, 8, 9, the spine or backward process. st, 8, the two tops of the spine. u, 9, the descending process of the third rack. x, 9, the ascending process. y, the transverse process of the third rack. a, 8, 9, the hole of this transverse process. β, 9, the upper hollowed part of the body of the third rack. β, 9, the *Sinus* or cavity which maketh the lower part of a hole through which the conjugations of the nerves are led. ε, 7, the upper part of the same hole.

And by this articulation the head is bended forwards and backwards, as it is moved to the sides by the articulation of the first Rack-bone with the second. That process is bound by two Ligaments, the first of which being greater and broader is external, comprehending in the compass thereof all the upper articulation, ascending from the rack-bones to the head, or rather descending from the head to them, as any other Ligament going from one bone to another; The other is the stronger and also incompasses the articulation mixing its self with the gristle, which by its interposition binds together all the Rack-bones, the first excepted, as you may see in pulling asunder the Rack-bones of a Swine; and the whole Spine or Back-bone is tyed together and composed throughout with such Ligaments.

The Holy bone is composed of 4. *Vertebrae* (or rather of five, or six, as in the figure following) besides the Rump-bone, it receives, and holds fast the *Ossa Ilium*, or Hanch-bones, and is as a Basis to all the Rack-bones placed above it, whereby it comes to pass that the Rack-bones from the Head to the Holy-bone grow still thicker, because that which supports ought to bigger than that which is supported. There is a certain moisture, tough and fatty, put between the Rack-bones, as also in other joynts, to make them glib and slippery, that so they may the better move. Whilst this motion is made, the Rack-bones part one from another.

The commodities or uses of the Spine are said to be four. The first is, that it is, as it were, the seat and foundation of the composure and construction of the whole body, as the Carcass is in a ship. The second, that it is a way or passage for the marrow. The third is, because it contains and preserves the same. The fourth is, that it serves for a wall or bulwark to the entrails, which lye and rest upon it on the inside. And because we have fallen into mention of Ligaments, it will not be amiss to insert in this place, that which ought to be known of them. First, therefore, we will declare what a Ligament is, then explain the divers acceptions thereof, and lastly prosecute their differences.

Therefore a Ligament is nothing else than a simple part of mans body, next to a bone and Gristle the most terrestriall, and which most usually arises from the one or other of them either mediately or immediately, and in the like manner ends in one of them, or in a Muscle, or in some other part; whereby it comes to pass that a Ligament is without blood, dry, hard, cold, and without sense, like the parts from whence it arises, although it resemble a Nerve in whiteness and consistence, but that it is somewhat harder.

A Ligament is taken either generally or more particularly; in general, for every part of the body, which ties one part to another, in which sense the skin may be called a Ligament, because it contains all the inner parts in one union. So the *Peritoneum* comprehending all the naturall parts, and binding them to the back-bone: so the membrane investing the Ribs, (that is, the *Pleura*) containing all the vitall parts; thus the membranes of the brain; the nerves, veins, arteries, muscles, membranes, and lastly all such parts of the body, which bind together and contain other, may be called Ligaments, because they bind one part to another; as the nerves annex the whole body to the brain, the Arteries fasten it to the heart, and the veins to the liver. But to conclude, the name of a Ligament more particularly taken, signifies the part of the body, which we have described a little before.

The differences of Ligaments are many, for some are membranous and thin; others broad, others some thick and round, some hard, some soft, some great, some little; some wholly gristly, others of a middle consistence between a bone and a gristle, according to the nature of the motion of the parts, which they bind together in quickness, vehemency and slowness. We will shew the other differences of Ligaments, as they shall present themselves in dissection.

By what articulation the head is bended backwards and forwards.

Why it is without sense?

What parts may be called Ligaments in a general signification?

The differences of Ligaments properly so called.

CHAP. XVII.

Of the Muscles of the Neck.

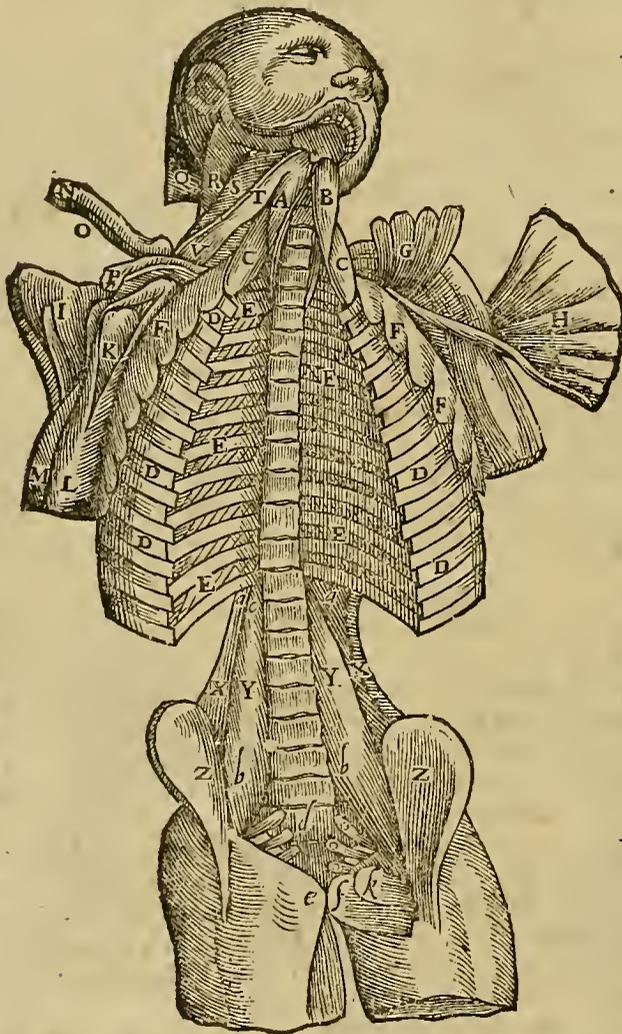

Their number.

The Muscles of the neck as well proper as common, are in number twenty, or else twenty two, that is, ten, or eleven on each side; of which, seven only move the head, or the first *vertebra* with the head; the other three or four, the neck it self.

Of the seven which move the head, and with the head the first *Vertebra*, some extend and erect it, others bend and decline it, others move it obliquely, but all of them together in a successive motion move it circularly, and the like judgment may be of the Muscles of the Neck.

The fourth Figure of the Muscles. This Figure sheweth the cavities of the middle and lower bellies, the bowels being taken out, but most part of the bones and muscles remaining.

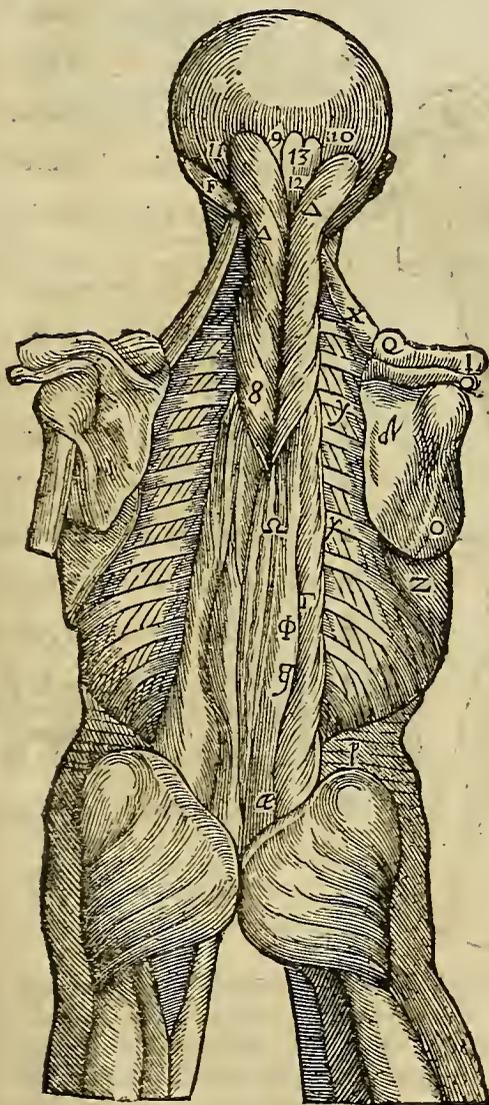

- AB. The first muscle bending the neck called *Longus*.
 CC. The second bender of the neck called *Scalenus*.
 DDDD. The outward *intercostal* muscles.
 E E E E, The inner *intercostal* muscles.
 F F F, The second muscle of the chest called *serratus maior*.
 G, The first muscle of the shoulder-blade called *serratus minor*, separated from his originall.
 H, The first muscle of the arm called *Pectoralis*, separated from his originall.
 I. The second muscle of the arm called *Deltoides*.
 K. The bone of the arm without flesh.
 L, The first muscle of the cubit called *Biceps*.
 M. The second muscle of the cubit called *Brachialis*.
 N. The clavicle or collar-bone bent backward.
 O. The first muscle of the chest called *subclavius*.
 P, The upper process of the shoulder-blade. Q. The first muscle of the head called *obliquus inferior*. R. The second muscle of the head called *Complexus*. S. The fourth muscle of the shoulder-blade called *Levator*. T V. The two bellies of the fourth muscle of the bone *Hyois*.
 X X. a a. The fift muscle of the back whose originall is at a a. Y Y. b b. c c. The sixt muscle of the thigh called *Psoe*, whose originall is at c c. and tendon at b b. Z Z. The seventh muscle of the thigh. d. the holy bone. o o o. The holes of the holy bone, out of which the nerves do issue. e. A portion of the fifth muscle of the thigh arising from the share-bone. f the share-bone bared. k. The ninth muscle of the thigh or the first *circumflexor*.

But before I can come to the description of their originall and insertion, I must admonish thee, that the 2 Muscles of the shouder-blade must first be taken away by dissection; that is, the *Trapezius*, or Table-muscle, and the *Rhomboides*, or square-muscle; whose originall and insertion that we may the better demonstrate, (or rather the action by which we seek that originall and insertion,) they must be pulled up, beginning at their insertion, which is at the shoulder-blade (as shall be shewed in the proper place) turning them up towards their originall, that is, to the Spine. Besides the less *Rhomboides*, the hinder, and upper (called also the *Dentatus* or toothed-muscle) must be raised from its originall, which is at the three lower Rack-bones of the Neck and the first of the back, and turned up to its insertion, which is at three spaces of the lower ribs

nigh to the hind, and upper angle of the Shoulder-blade, as shall be shewed in fit place hereafter. These muscles thus raised up, the 4 muscles which erect and extend the head must be taken away, and then those two which move it obliquely, and lastly one which bends, or declines, for thus anatomical order requires. Yet if you think good, you may, not hurting the other, first of all cut away that which is called the *Mastoides*, which declines or bends the head. For these 4, which lift up and extend the head, the first from the figure of the spleen is called the *Splenius*, it ascends from the 5, upper spines of the back and the 4, lower of the neck, and is obliquely inserted at the back part of the head and the mamillary process, whence you may raise it towards its originall. The second by reason of its compo sure is called *Complexus*; this passing from the third, fourth and fifth transverse process of the back and often from the first of the neck, ascends directly to the back part of the head, in compassing the lower and side part of the neck, you may easily take it up; if you begin at the spine, and so go forwards to the transverse processes and mamillary processes of the nowl-bone. This *Complexus* may be divided into two or three muscles, but that with some difficulty, by

The fifth Figure of the muscles in which some muscles of the Head, Chest, Arm, and shoulder-blade are described.

I. The process of the shoulder-blade, called the top of the shoulder.

O. The fourth muscle of the arm or the greater round muscle, to which Fallopius his right muscle is adjoined, which some call the lesser round muscle.

Q. Q. The sixth muscle of the arm or the upper bade-rider.

X. The second muscle of the shoulder-blade or the Levator or heaver.

Z. The second muscle of the chest or the greater Saw-muscle.

Y. The fifth muscle of the chest or muscle called Sacrolumbus.

αβ. His place wherein he cleaveth fast to the longest muscle of the back.

γγ. The tendons of the muscle obliquely inserted into the ribs.

ΔΔ. The first pair of the muscles of the head or the Splinters.

Ch. 8. 9. Their length whose beginning at 8 and insertion at 9.

10. 11. The sides of this muscle.

12. That distance where they depart one from the other.

13. The two muscles called *Complexi*, near their insertion.

φ. The second muscle of the back or the Longest muscle.

α. The fourth muscle of the back or the Semi-spinatus.

δ. The shoulder-blade bare.

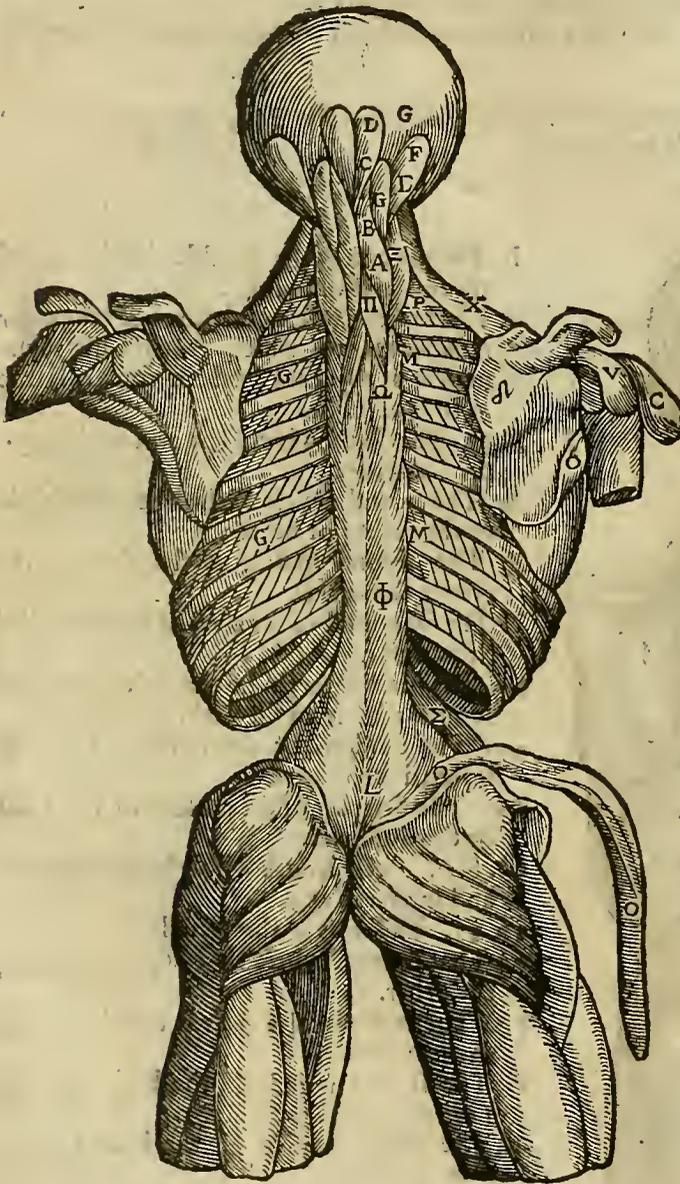

p. A part of the transverse muscle of the Abdomen.

reason of its folded texture. The third and fourth, which be two of the eight little muscles, being four on each side, do ascend somewhat obliquely, the first truly from the whole side of the second *Vertebra*. The second from the whole side of the process of the first *Vertebra*, which it hath in stead of a spine; they ascend to the back part of the head just against the spine; these two muscles by the consent of all Anatomists are called right, or direct muscles, only moving the head: these truly must not be pluckt from the places of their originall, nor insertion, but only bound by a string put under them, that so they may be the more easily shewed. On each side follow two oblique muscles, one whereof only moves the head; the other primarily the first *Vertebra*, but secondarily, and by accident

The Recti. or
2 right mus-
cles.

accident the head it self. For the first, contrary to the opinion of some, it arises from the transverse process of the first rack-bone, and then is inserted, above the insertion of the first right muscle: the which in like manner you must lift up, by something put underneath it, but not separate it. The other entering forth of the spine of the second *Vertebra*, is inserted at the process of the first, contrary to the original of the precedent, although some think otherwise. It will be convenient in the like manner only, to lift up this with a string, and not pluck him from his place, that so you may see how all these make a perfect triangle. The action of this muscle is contrary to the action of the precedent, as the contrariety of its original and insertion shew.

The sixth Figure of the muscles, shewing some of the muscles of the Head, Back, Chest, Shoulder-blade and Arm.

- A D.* the second pair of the muscles of the head, or the two *Complexi*, the first part is at *A D.*
BC. the second part *EF*, the third part rising up under *G* and inserted at *F.*
G. the fourth part of this muscle or the right muscle of the head according to *Fallopins*, which *Vesalius* made the 4 part of the 2.
GG. (Betwixt the ribs) the external *Intercostal* muscles.
L. the original of the 2. muscle of the back.
M. His tendons at the rack-bone of the neck.
O. the upper *O* the fourth muscle of the arm or the greater round muscle.
OO. the lower, the 6 muscle of the chest, or the *Sacrolumbus* hanging from his original.
Q. the sixth muscle of the arm or the upper *Bladerider* inverted.
V. the third ligament of the joint of the arm.
X. the fourth muscle of the shoulder-blade or the *heaver*.
Z. the second muscle of the Chest, or the greater *Saw* muscle.
Z. the three muscles of the neck called *Transversalis*.
Π. the 4. muscle of the neck called *Spinatus*.
Σ. the first muscle of the back, or the *Square* muscle.
Φ. the 2. muscle of the back or the *Longest*, whose original is at *L* and his tendons at the *Vertebrae* at *MM.*
Ω. the fourth muscle of the back called *Spinatus*.
δ. the back of the shoulder-blade stayed.

Which may be truly called the proper muscle of the neck. The two motions of the head.

Wherefore when the first oblique moves the head obliquely forwards, the second pulls it back by the first *Vertebra*, this with his associate of the other side, may be truly termed the proper muscles of the neck, because they belong to no other part; whereas it is contrary in other muscles. But we must note, that the head (according to *Galens* opinion) hath two motions, one directly forwards and backwards, as appears in beckning it forwards, and casting it backwards; the other circular.

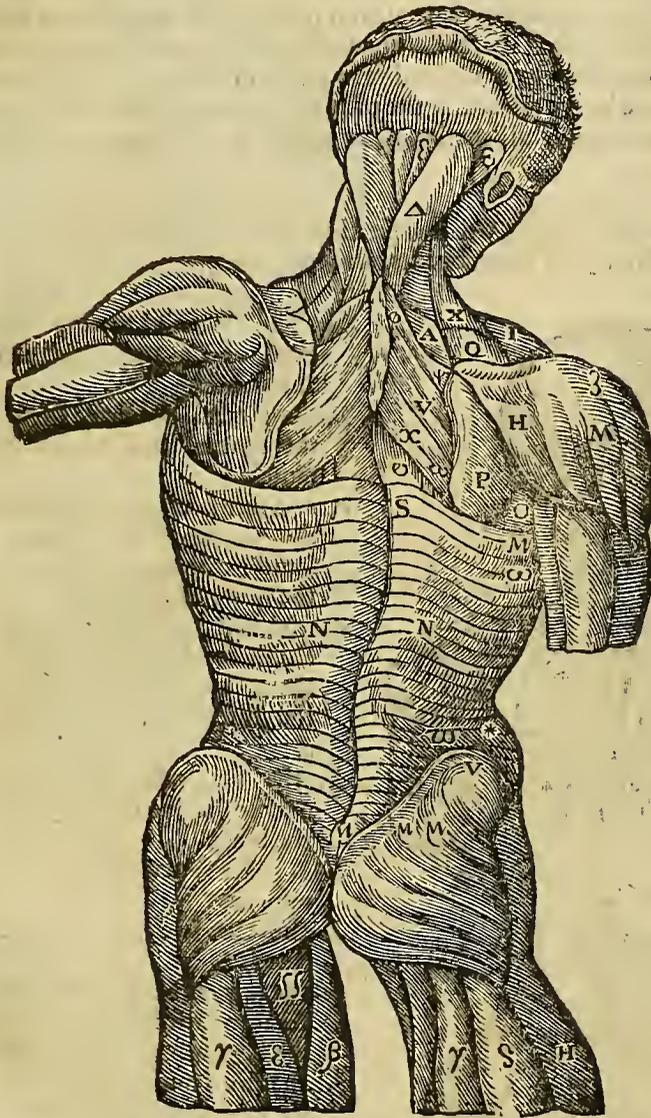

The first in *Galens* opinion is performed by the first *Vertebra* moved upon the second; the second by the head moved upon the first *Vertebra*; for which he is reproved by the latter Anatomists, who teach that the head cannot be turned round or circularly upon the first *Vertebra* without putting it out of joint.

For the last which bends the head, it ascends from the upper and side part of the *Sternum*, and the next part of the clavicle, obliquely to the *Apophysis Mastoides* or mamillary process of the hind part of the head, whence it is called the *Mastoides*. You may divide this by reason of its manifold original rather into two, than into three muscles. But it had been better that the head might have been moved every way, equally back-

The *Mastoides*?

backwards and to the right and left sides; but thus it would often have been strained to our great damage and danger of life; neither could there have been such facility of motion without a looseness of the joint. Therefore nature had rather bestow upon the head an harmless faculty of fewer motions, than one furnished with more variety, but with a great deal more uncertainty and danger. Wherefore it hath made this juncture not laxe or loose, but stiffe and strong.

laris Superior. S. the beginning of the third muscle of the arm called *Latissimus*. V. the third muscle of the blade called *Rhomboides*. phi X. his originall from the spines of the rackbones. J. his insertion into the basis of the shoulder-blade. chi. the fourth muscle of the blade called *Levator*. * a part of the oblique descendent muscle of the *Abdomen*.

After the shewing of these muscles, we must come to three or four of the neck, of which number two (which some reduce to one) extend, another bends, and the last moves side wayes, and all of them with a motion succeeding each other turn it about as we said of the muscles of the head. The first of these which extend, taking its originall from the six transverse processes of the six upper rack-bones of the back, or rather from the root of the oblique, ascends directly to the spine of the second vertebra of the neck, and the oblique process thereof; some call it the *Transversarius*; that is, the transverse-muscle. This, if you desire to take it away, it is best first to separate it from the spine, then to turn it upwards to the transverse processes; unless you had rather draw it a little from its partner and companion in that place where their originals are distinct, seeing it is the last and next to the bones.

Marvell not, if you find not this distinction of their originall, so plain and manifest, for it is commonly obscure. For the muscle *spinatus*, as it most commonly comes to pass, arising from the roots of the seven upper spines of the back, and the last of the neck, is inserted into other spines of the neck, so that it might easily be confounded with the former

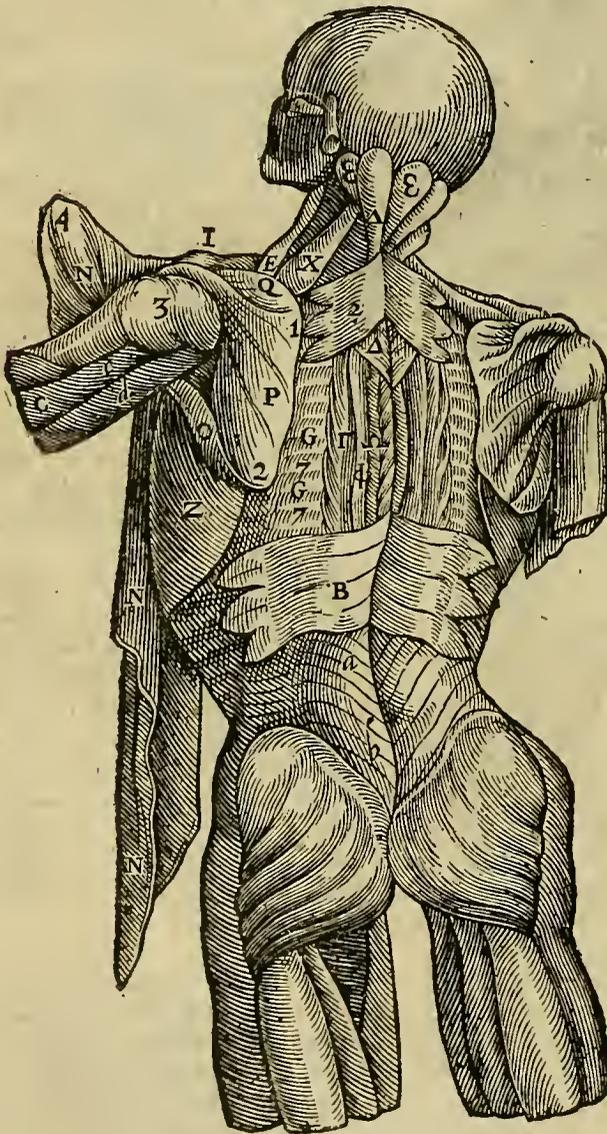

The *Transversarius*.

The *Spinatus*.

by Galen. The third bends the neck, and arising within from the body of the five upper *Vertebrae* of the back (though with a very obscure originall, specially in lean bodies) it ascends under the gullet alongst the neck, even to the nowl-bone, into whose inner part it is obscurely inserted. Wherefore it is likely that it helps not only to bend the neck, but also the head. This muscle is made of oblique fibers proceeding from the body of the *Vertebrae*, all the way it passes to the transverse processes of the other *Vertebra*. But it seems with its copartner which is opposite to it, to make a certain hollow path upon the bodies of the *Vertebrae*, to the gullet, and it is called the long muscle. The fourth and last, which we said moves the neck to one side, is called *Scalenus* from the figure thereof; it ascends from the hinder and upper part of the first rib of the Chest, inserting its self into all the transverse processes of the neck by its fibers, which as it were for the same purpose, it hath sufficiently long, that it may fasten it self from the furthest and lowest process of the neck into the first or highest thereof. The passage of the nerves through this to the arm makes this muscle seem double or divided into two. For the veins and arteries pertaining to the neck, they have been declared in the proper Chapters of the distributions of the vessels; it remains that you note, all these muscles receive nerves from the *Vertebrae* whence they arise.

CHAP. XVIII.

Of the Muscles of the Chest and Loins.

WE must now speak of the Muscles both of the Chest which serve for respiration, as also of the Loins. But first we must know that the hind part of the Chest called the *Metaphrenum*, or back, consists of twelve *Vertebrae*, the Loins of five, all which differ not from the *Vertebrae* of the neck, but that they are thicker in their bodies than these of the neck; neither are they lesser in holes, neither have they their transverse processes perforated or parted in two as the rackbones of the neck have. Besides each of these rack bones alone by it self, on each side in the lower part thereof makes a hole, through which a nerve hath passage from the spinall marrow to the adjacent parts, when on the contrary in the *Vertebrae* of the neck, such holes or passages are not made, but by meeting together of two of them.

Concerning the processes of the Rackbones of the Chest, whether transverse, right or oblique, they differ nothing from these of the neck (I mean even to the tenth) but that the transverse seeing they are not perforated, as we said before, do as it were sustain the ribs, being straitly bound to them with strong ligaments both proper and common; but after the tenth *Vertebra* of the back, the two other of the back, and all those of the loins are different, not only from those of the neck, but also from the ten first of the back, by reason of their oblique processes, because from the eleventh (which is received, as well by that which is above it, as by that under it, for the strength of the whole back, and the easier bending thereof without fear of fracture or dislocation) the above mentioned processes of the lower rack bones which were wont to receive, are received; as on the contrary they receive which were wont to be received. They differ besides from all the forementioned, by reason of their spines, because from the eleventh they begin by little and little to look upwards, contrary to the former.

But if any ask, how the tenth *vertebra* of the back may be termed the midst of the

In what the *Vertebrae* of the neck and loins agree and differ.

How the tenth *vertebra* of the back, may be said to be the middle of the spine.

Muscles always receive their nerves in their heads.

spine, being the whole spine consists of twenty four *vertebrae*? He may know that this may be true, as thus; if the six bones of the holy bone, and the fourth of the Rump (being more gristly than bony) be numbered amongst the bones of the Spine; for then from the setting on of the head to the eleventh rack bone of the back are seventeen in number, and so many from thence downwards.

But let us return to the muscles of the Chest serving for respiration. First, you must know that these Muscles are fouricore and nine, that is, on each side forty four, alike in strength, thickness, site, and action; and one besides in the midst which they call the *Diaphragma* or midriff. Of these forty four, there are twenty two which dilate the chest in drawing in the breath; that is, the *Subclavius*, the *Dentatus*, or *Serratus major* in the opinion of some, both the *Rhomboides* or *Serrati postici*; the oblique ascendent of the lower belly, the eleven *Intercostales*, and the six *Intercartilaginei externi*. On the contrary, as many contract the breast in expiration; to wit, the *Sacrolumbus*, the oblique descendent, the Right and transverse of the lower belly, the inner *Triangular*, the six *Intercartilaginei*, and the eleven inner *Intercostales*. Of these twenty two dilating the Chest, the first from the site is called the *Subclavius*, for it descends obliquely from the inner and forepart of the *Clavicula* or Caller bone, into the gristle of the first rib, even to the *Sternon*, and dilates it. The second is the *Serratus major*, the greater Saw muscle arising according to the opinion of some from the whole *basis* of the shoulder blade on the inside, and it is transversely inserted into the nine upper ribs, producing certain toothed or saw-like processes running further to the bones of the rib, than to the spaces between them, or Intercostal muscles, whereupon it hath the name of the Saw muscle; yet some have referred this muscle to them of the shoulder blade. The third descends from the three lower spines of the neck, and the first of the back, by means of a membranous and most thin ligament, into the three or four upper ribs, running further into their spaces or Intercostal muscles, than into the ribs themselves, whereupon it is called *Serratus posterior & superior*, that is, the hinder and upper Saw muscle. The fourth in like manner ascends by means of a membranous and thin ligament from the three upper spines of the loins, and the two last of the chest, or back, into three or four of the lower, or last of the bastard ribs, sent forth further into them or their bones, than into the Intercostal muscles possessing the spaces between them, wherefore it is called *Serratus posterior & inferior*, the hinder and lower Saw muscle. Moreover these two last muscles have been called by a common name from their figure the *Rhomboides*, that is, the square muscles. The fifth which we said was the ascendent of the *Epigastrium*, hath already been sufficiently described in his place. The eleven *Intercostales externi*, or external Intercostal muscles descend obliquely from the back part of the lower side of the upper rib, into the forepart of the upper side of the rib lying next under it, after a quite contrary manner to the six *Intercartilaginei*, who having like originall and insertion amongst the gristles, as the Intercostal amongst the ribs, descend obliquely from the forepart backwards. And thus much of the muscles dilating the Chest in inspiration.

But the first, of the other muscles, being as many in number, which contract the Chest in expiration, arising from the holy-bone, and the oblique processes of the loines, ascends (firmly and confusedly adhering with the *Musculus sacer*, or holy muscle, which we shall describe hereafter) to the roots of the twelve ribs, imparting in the ascent a small tendon to each of them, by which it draws these ribs towards the transverse processes; and by reason of its Originall it is called *Sacrolumbus*, that is, the Holy loin-muscle.

The second, third, and fourth, which we said were the oblique descendent, right, and transverse of the *Epigastrium*, have been formerly described in their place.

But by the way you must note that these three muscles of the *Epigastrium* help expiration rather by accident, than of themselves, to wit, by driving back the midriff towards the lungs by the entrails, which also they force upwards, by drawing the parts into which they are inserted towards their Originall. The fifth which we called the *Triangulus*, or *Triangular*, may be called the *compressor* of the gristles, which proceeding from the inner sides of the *Sternon*, goes to all the gristles of the true ribs; this is more apparent under the *Sternon* in beasts, than in men, though it be not very obscure in them neither. For the internal Intercostal muscles, in my judgment, they arise from the lower sides of the upper rib, & descending obliquely from the forepart backwards, are inserted into the upper side of the rib next under it; so that they may follow the production of the fibers of the external *Intercartilaginei*; as the six internal *Intercartilaginei* follow the site of the external Intercostal proceeding from behind forwards; wherefore as well the Intercostal, as the *Intercartilaginei*, every where intersect each other, after the similitude of the letter X. I know some have written that the internal muscles (whether intercostal or *Intercartilaginei*) ascend from the upper side of the lower rib forwards, and backwards.

But if this were true, it would follow that these muscles admitted their nerves in their tail, and not in their head, seeing the nerve always goes under the rib, and not above it.

The last muscle of the chest, that is, the *Diaphragma* or Midriff, is sufficiently described before; wherefore it remains we describe the muscles of the Loins. These are six in number, on each side three, equal in thickness, strength and situation; one of these bends, and the other two extend the Loins; it is called by reason of the figure the *Triangulus*, or Triangular which bends the Loins, it ascends from a great part of the hind side of the Hanch-bone into the transverse processes of the Loins, and the last of the Chest on the inside, for which cause it is made of fibers short, long, and indifferent, answering to the nearness or distance of the said processes. The first of the extenders is called the *Semispinatus*, because even to the middle of its body it takes the originall from the spines of the Holy bones and Loins; this with its oblique fibers ascends from all the said spines to the transverse processes, as well of the Loins as Chest. The other is called *Sacer*, the Holy-muscle, because it takes its originall from the Holy-bone, or the sides thereof; it ascends with its oblique fibers to the spines of the Loins, and of the eleven lower Rack-bones of the Chest.

The midriffe.
The muscles of the loins.
They are three pair.

Semispinatus;

Sacer.

CHAP. XIX.

Of the Muscles of the Shoulder-blade.

Now we must describe the muscles of the extreme parts, and first of the Arm; taking our beginning from these of the shoulder-blade. But first, that we may the better understand their description, we must observe the nature and condition of the shoulder-blade. Therefore the blade-bone on that part, which lies next unto the ribs, is somewhat hollowed; wherefore on the other side it somewhat buncles out. It hath two ribs, one above, another below: by the upper is meant nothing else than a border or right line, which looking towards the temples is extended from the exterior angle thereof under the collar-bone, even to the Proesse *Coracoides* which this rib produces in the end thereof: By the lower, the under side which lies towards the lower belly and the short ribs.

The description of the blade-bone, or shoulder-blade.

Besides, in this shoulder-blade we observe the *basis*, head and spine. By the *basis* we understand the broader part of the shoulder-blade, which looks towards the back-bone. By the head we understand the narrower part thereof, in which it receives the head of the Arm in a cavity, indifferently hollow, which it produces both by it self, as also by certain gristles, which there fastned encompasse that cavity. This kind of cavity is called Glene.

The basis of the blades.
The head of the shoulder blade.

This receives and contains the bone of the arm, by a certain strong ligament encompassing and strengthening the joint, which kind of ligament is common to all other joints; this ligament arises from the bottom of the cavity of the shoulder-blade, and circularly encompasses the whole joint, fastning it self to the head of the arm; there are also other ligaments besides this, which incompasse and strengthen this articulation. By the spine is meant a proesse, which rising by little and little upon the gibbous part of the blade, from the *basis* thereof where it was low and deprest, becomes higher untill it ends in the *Acromion*, or upper part thereof. Nature hath made two productions in this bone (that is to say, the *Acromion* from the spine, and the *Coracoides* from the upper side) for the strengthening of the articulation of the arm and shoulder-blade, that is, lest the arme should be easily strained upward or forwards; besides, it is fastned to the clavicle, by the proesse *Acromion*.

The spine of the blade,
The processes

Acromion and *Coracoides.*
The muscles of the shoulder-blade.

The muscles which move the shoulder-blade are six in number, of which four are proper, and two common. The first of the four proper seated in the forepart, ascends from the bones of five or six of the upper ribs, to the *Coracoides*, which it draws forwards, and is called *Serratus minor*, that is, the lesser saw-muscle; which that you may plainly shew, it is fit you pull the pectorall muscle from the collar-bone, almost to the middle of the *Sternon*. The other first opposite against it, is placed on the fore side, and draws its originall from the three lower spines of the neck, and the three upper of the Chest, from whence it extends it self, and ends into all the gristly basis of the shoulder-blade, drawing it backwards; it is called the *Rhomboides*. The third from its action, is called the *Levator*, or the heaver, or lifter up, seated in the upper part, it descends from the transverse processes of the four first *Vertebrae* of the neck into the upper angle and spine of the blade. The fourth called *Trapezius*, or the Table-muscle, is seated in the back-part and is membranous at the originall, but presently becomes fleshy: it arises from almost all the back-part of the head, from all the spines of the neck, and the eight upper *Vertebrae* of the chest, and then is inserted by his nervous part, almost into the whole basis of the blade; extending it self above the muscles thereof, even to the midst of its spine, where being fleshy it is inserted even to the *Acromion*, the upper part of the clavicle, and in some sort to the upper rib. This muscle hath a threefold action, by reason of its triple originall. The first is to draw the shoulder-blade towards its originall, that is, to the nowle, and spine of the neck; the other is to draw it towards the back, because of the contraction of the middle or

Serratus minor.

Rhomboides.
Levator.

Trapezius.

trans-

transverse fibers which lead it directly thither; and the other is to draw it downwards by reason of the original it hath from the fifth, sixth, seventh and eighth spine of the *Vertebrae* of the Chest.

But we must note, that these divers actions are not performed by this muscle, by the assistance of one only nerve, but by more, which come into it by the spinall marrow, by the holes of the *Vertebrae*, as well of the neck as the chest, from whence it takes the original. For the two other which are the common muscles of the blade, and arm, or shoulder, we will describe them with the muscles of the shoulder or arm: for one of these which is called the *Latissimus*, that is, the broadest, ascends from the holy-bone to the shoulder-blade and arm.

Latissimus.

Pectoralis.

The other the named *Pectoralis* comes from the *Sternum* and collar-bone to the shoulder-blade and arm.

CHAP. XX.

The description of the Hand taken in generall.

Now it befits us to describe in order the muscles of the arm; but first we must know, what it is that we call the arm. But seeing that cannot fitly be understood, unlesse we know what the hand is, seeing that the arm is a part of the hand; therefore first we must define what a hand is, and then divide it into its parts. Therefore the hand is taken two manner of waies, that is, generally and

specially.

What is meant by the hand in generall.

The hand generally taken, signifies all that which is contained from the joyning of the arm to the shoulder-blade, even to the ends of the fingers. But in particular it signifies only that which is comprehended from the furthest bones of the cubit, or the beginning of the wrist, to the very fingers ends.

Therefore the hand in generall is an instrument of instruments, made for to take up and hold any thing. It is composed of three great parts, that is, of the Arm, Cubit, and Hand, vulgarly, and properly so called; but the hand taken thus in particular is again divided in three other parts, the *Carpus* or *Brachiale*, the wrist, the *Metacarpium* or *Postbrachiale*, the after-wrist, and the fingers; all these parts (seeing each of them are not only organical parts, but also parts of organical parts) are composed of all, or certainly of the most of the similar parts; that is, of both the skins, the fleshy pannicle, the fat veins, arteries, nerves, muscles or flesh, coats both common and proper, bones, gristles, and ligaments, all which we will describe in their order.

The differences of the hand from the site thereof.

But first I think good to admonish you of the differences of the hand taken from the site thereof, and these differences are six in number, the fore, the hind, the internal, the external, the upper and lower side or part thereof.

By the fore we mean that part which looks directly from the thumb to the shoulder: by the hind, we understand the part opposite to it, which from the little finger looks towards the basis of the shoulder-blade. By the inside we signifie that part which lies next to the sides of the body, when the hand retains its naturall site; by the outside, the part opposite to it. The upper and lower side you may know by the very naming thereof.

Why the hand is divided into so many fingers

The hand properly so called is divided into five fingers, that so it may hold and take up bodies of all figures, as round, triangular, square and the like, and gather up the least bodies with the fingers ends, as needles, pins, and such like.

Why the nails are added to the soft flesh of the fingers.

Nature hath bestowed two hands upon us, that so they may help each other, each moving to each side. But for the taking up and holding of small bodies it was fit, that the fingers of their own nature soft, should be armed with nails, that consisting of soft flesh and an hard nail, they might serve for all actions; for the nail is a stay to the soft flesh, which otherwise would turn away in meeting with an hard body; the use of the nails is to scratch, shave, and pull off the skin, to rend, pinch, and pluck asunder small bodies. They have not bony hardnesse, that so they might not break but bend.

Why the nails grow continually.

Yet other creatures have hard nails to serve them in stead of weapons. Their figure is round, because such a figure is lesse obnoxious to externall injuries; and by reason they are subject to wearing, they grow continually.

Nature hath placed flesh on the inner and side part of the fingers, so to presse more straitly, the things they once take hold of, so that by holding them close together we can hold water that it may not run out. The length of the fingers is unequal, that when they are opened and stretched forth, they make as it were a circular figure; for so it comes to passe, that the hand can hold all bodies, but especially round.

It remains that we prosecute the distribution of the veins, arteries, and sinews, which run over all the parts of the hand taken in generall and particular, whereby we may more commodiously hereafter handle all the proper parts thereof.

CHAP. XXI.

The distribution of the Subclavian vein, and first of the Cephalica, or Humeraria.

Two large veins descend from the Subclavian, the one from the lower side, the other from the higher. Yet sometimes, and most usually, both these proceed from the same common orifice, as in men of a low stature in the arm. The one of these is called the *Axillaris*, the other the *Humeraria*, or *Cephalic*; therefore this Cephalick passing forth of the Subclavian runs superficially along the fore-side, between the muscle *Deltoides*, and the Tendon of the pectorall muscle, and descends in the midst between the common coat of the muscles, and the fleshy pannicle, even to the bending of the cubit, where in lean bodies it is plainly to be seen, whereas in fat bodies it is hardly to be perceived, being as it were buried in abundance of fat. This vein having in its descent, sent forth some small branches, both to the skin, as also to certain muscles over which it runs, is divided into two, a little above the outward protuberation of the arm. One of the branches into which it is divided descending obliquely to the fore part of the cubit, a little below the bending of the cubit, it meets, and is united with the like branch in the same place, as shall be shown hereafter.

That which arises from this concurrence, is called the median vein, because it arises from two branches, and is seated between them. They usually open this median vein in the diseases of the head and liver, which require Phlebotomy; but if it shall not be sufficiently manifest, when you judge it must be opened, for a generall evacuation of the whole body; you may cut one of these branches, by whose concurrence it is made, which you shall think the fitter; and because each branch draws from the next parts, according to the straightness of the fibers, rather than from the opposite side; if you would evacuate the head, and liver equally, by opening either of these branches, it is convenient that opening that branch (for example) which comes from the Cephalick, you presently lay your thumb upon it, untill you suppose you have drawn a just quantity of blood from the liver, by the *Basilica*, or liver-vein; which done, you may take off your thumb, and suffer the blood to follow freely, by the open branch of the Cephalick, untill you have drawn as much blood as you shall judge requisite; otherwise you will draw it but from one part, to wit, the head. So you shall evacuate it only from the liver, if you open the branch which comes from the *Basilica*, and concurs to the generation of the median.

Moreover, when there is need to open the *Basilica*, and it shall be no where conspicuous, the Cephalick or median being easie to be discerned at the same time, you may in stead thereof open the median, or if it be not to be found, the Cephalick, pressing but the trunk thereof with your thumb, as we said before, lest the head should be evacuated in stead of the liver. You may doe the same in the *Basilica*, if when there shall be necessity to open the Cephalick, it shall not appear. Most of those which at this day open a vein, in stead of the median, open that branch of the *Basilica* which ascends together with the Cephalick to make the median. But you must understand that the median descends between the two bones of the cubit, even to the end thereof, and then divided into many branches, it is at length spent on the back of the hand behind the thumb, the fore and middle fingers, or the after-wrist. Sometimes it runs back into the following branch, and then at the wrist it departs from it, to be bestowed upon the forementioned parts. The other branch of the Cephalick, which we may call the fore and outward Cephalick, descending directly down to the midst of the wand, thence wanders overthwart in to the hind part of the arm, where encreased with a branch from the *Basilica*, it is distributed over all the back of the hand, which with the median it nourisheth. But the branches of these veins do so run through the forenamed parts, that by the way they yeeld them necessary provision.

CHAP. XXII.

The Description of the Axillary vein.

The Axillary arising at the insertion of the pectorall muscle, or a little higher, after it hath produced the two *Thoracice* it is divided under the tendon of that muscle into two fair branches, that is to say, into the inner deep Axillary, and the skin or outward Axillary. The deep or inner having still for his companion in his descent, the axillary artery, and the nerves of the third conjugation, after it hath produced the small externall musculous of the arm, it goes into the bending of the elbow, where running somewhat deep with the artery and nerve into the muscles of the cubit, it is divided into three other branches, of which one descending with the wand, slides under the ring, into the inner side of the hand, and hath bestowed two small branches on the thumb, two others on the fore, and one upon the middle-finger, so that all of them ascend by the sides of these fingers, the other descending with the artery,

The Cephalick vein.

The median vein.
How by opening the median vein, you may draw more or lesse blood from the head or liver.

The axillary is divided into the deep axillary, and outward axillary.

as the former alongst the cubit, sends branches to the rest of the fingers, like as the former. The third goes on the foreside between the two bones even to the wrist, and the square muscle.

But you must note that the veins of which we now treat, do not only make these divisions mentioned by us, but infinite others besides, as well in the parts which they goe to, as also in the inner muscles of the hand which they nourish.

And thus much of the internall and deep axillary vein. For the externall or skin Axillary (which first appears under the skin, especially in lean bodies, a little above the inward production of the arm) it is divided in that place into two branches, the one whereof descending to the bending of the arm meets, and is united with the Cephalick branch, sooner or later, that so it may produce the median, as we formerly mentioned.

The other branch having sent forth many shoots of a different length and thicknesse, as well into the skin, as into the other neighbouring parts, descending alongst the lower side of the bone of the cubit, properly so called, is at length spent upon the fore and outward Cephalick branch, which we said descended alongst the wand; and thus united, they run over all the hand, where in the right hand, between the middle and fore finger, they make the *Salvatella*; but in the left, in the same place, they produce the *Splenitica*.

The *Salvatella*
and *Splenitica*.

But alwaies remember, (if in dissection you find any thing otherwise than we have delivered it) that the distribution of the vessels is so various, especially in the hands) that there can no certain rule be delivered thereof.

CHAP. XXIII.

The Distribution of the Axillary Artery.

THe Axillary artery from the first originall, which is presently after the two *Thoracicae*, descending between the muscle called *Biceps*, or the two headed muscle, and the *Brachieus*, with the deep Axillary vein, distributes a large branch amongst the outward muscles of the arm, which extend the cubit, and is spent in the externall muscles of the same, which arise without, from the productions of the arm.

And this is called the *Ramus Musculus*, or Musculous branch, as also the vein that accompanies this arterie. Then this artery when it comes to the bending of the cubit, thrusting it self into the muscles bending the fingers, communicates certain branches to the parts pertaining to the dearticulation of the cubit with the shoulder, and other parts there situate, as it did in the upper parts, by which it descended hither. Verily it may be a generall rule; that every vessell sends or bestows certain portions thereof by the way to all the parts by which it passes. But if you should ask, why I have not prosecuted these productions; I would answer; I never intended to handle other than large and fair branches of vessels, by rash incision of which, there may happen danger of death or a disease. For it would be both an infinit and needles busines to handle all the small devarications of the veins, arteries, and nerves. Therefore this artery sunk into these muscles, when it comes almost to the midst of the cubit, presently or a little after it is divided into two large branches, the one of which alongst the wand, and the other alongst the cubit is carryed into the hand on the inside under the Ring. For both these branches are distributed and spent upon the hand after the same manner as the branches of the internall Axillary vein, that is, having sent by the way some little shoots into the parts by which they passe, at the length the branch which descends by the Wand of the remainder thereof, bestows two sprigs upon the thumb, on each side one, and two in like manner on the fore finger, and one on the middle; the other which runs alongst the Ell, performs the like office to the little and the middle or ring finger, as you may see by dissection.

An Anatomical
Axiome.

CHAP. XXIV.

Of the Nerves of the Neck, Back, and Arm.

The 7 pair of
nerves of the
neck.

The first pair.

NOW we should handle the sinewes of the Arm, but because these proceed from the nerves of the neck and back; I think it fit therefore to speak something of them in the first place.

Therefore from the neck there proceeds seven pair of nerves, the first of which proceeds from the nowl bone, and the first *Vertebra* of the neck; as also the first pair of the Back from the last *Vertebra* of the neck, and the first of the Chest. But all these nerves are divided into two or more branches of the first pair (that is to say, on each side) go, the one to the small right muscle, ascending from the first rack-bone of the neck to the nowl bone, the other to the long muscle on the foreside of the neck.

The second
pair.

The branches of the second pair are distributed, some with a portion which they receive from

from the third pair over all the skin of the head; the two others go as well to the muscles, which are from the second *Vertebra* to the backpart of the head, and from the same to the first *Vertebra*, as also to the long muscle before mentioned.

One of the third pair of sinews is communicated to the head, as we said before, but others to the Muscles which extend, or erect the head and the neck; there is also one of these distributed into the neighbouring side muscle and part of the long.

The nerves of the fourth pair go, one to the muscles as well of the neck as the head, and to the broad muscle; the other after it hath sent some portion thereof into the long muscle and the side muscles of the neck, it descends with a portion of the fifth and sixth pair to the Midriff. One of the branches of the fifth pair is bestowed on the hind muscles of the neck and head, the other upon the long muscle and midriff; the third is communicated to the *Levatores*, or Heaving muscles of the arm and shoulder.

One of the nerves of the sixth pair goes to the hind muscles of the neck and head, another to the Midriff, the third with a portion of the seventh pair of the neck, and of the first and second of the chest go to the arms and heaving muscles of the shoulder-blade.

One of the branches of the seventh pair runs to the broad muscle and to the neighbouring muscles both of the neck and head; another encreased with a portion of the fifth and sixth pair of the neck, and a third joyned to the second and third pair of the chest descending into the arm go to the hand.

But you must note that the muscles which take their original from many *Vertebrae*, whether from above downwards, or from below upwards, admit nerves not only from the *Vertebrae* from whence they take their original, but also from them which they come near in their descent, or ascent.

There pass twelve conjugations of nerves from the rack-bones of the chest.

The first entering forth from between the last rack-bone of the neck and the first of the chest, is divided (that is, on each side, each nerve from his side) into two or more portions, as also all the rest. Therefore the branches of this first conjugation go some of them to the arms, as we said before, others to the muscles, as well these of the chest, as others arising there, or running that way.

The branches of the second conjugation are distributed to the same parts, that these of the first were.

But the branches of all the other conjugations even to the twelfth, are communicated, some to the intercostal muscles running within under the true ribs even to the *Sternum*, and under the bastard ribs even to the right and long muscles; and the costal nerves of the sixth conjugation are augmented by meeting these intercostal branches by the way as they descend by the roots of the ribs. Other particles of the said nerves are communicated to the muscles as well of the chest, as spine, as the same muscles pass forth, or run alongst by the *Vertebrae*, from whence these nerves have either their original, or passage forth.

Having thus therefore shewed the original of the sinews of the arm, it remains that we shew their number and distribution.

Their number is five or six; proceeding from the fifth, sixth, and seventh *Vertebra* of the neck, and the first and second of the chest. The first of which not mixed with any other from the fifth *Vertebra* of the neck, goes to the muscle *Deltoides* and the skin which covers it.

The other 4 or 5 when they have mutually embraced each other, not only from their first original but even to the shoulder, where they free themselves from this convolution, are distributed after the following manner.

The first and second descending to the muscle mentioned a little before, and thence sometimes even to the hand, is by the way communicated to the muscle *Biceps*, and then under the said muscle it meets and is joyned with the third nerve. Thirdly, it is communicated with the longest muscle of the cubit, in the bending whereof it is divided into two branches descending alongst the two bones of the cubit, untill at last born up by the fleshy pannicle it is spent upon the skin and inner side of the hand.

The third lower than this, is first united with the second, under the muscle *Biceps* then straightway separated from it, it sends a portion thereof to the arm which lies under it, and to the skin thereof; lastly, at the bending of the cubit on the fore side, it is mingled with the fifth pair.

The fourth the largest of all the rest, coming down below the third branch under the *Biceps*, with the internal axillary vein and artery, is turned towards the outward and backpart of the arm, there to communicate it self to the muscles extending the cubit, and also to the inner skin of the arm, and the exterior of the cubit; the remainder of this branch when in its descent it hath arrived at the joint of the cubit, below the bending thereof it is divided into two branches, the one whereof descending alongst the cubit is spent on the outside of the wrist; the other associating the wand is on the outside in like manner in two branches bestowed upon the thumb, and in as many upon the fore finger, and by a fifth upon the middle finger though more obscurely.

The fifth branch being also lower than the rest, sliding between the muscles bending and

extending the cubit, when it comes behind the inner protuberation of the cubit (in which place we said before the third Branch meets with this) it is communicated to the internall muscles of the same, and then divided into three portions, one of which on the outside alongst the middle of the cubit goes in two sprigs to the little finger, and so many to the middle finger, and one to the ring finger; the other two, the one without & the other within the ring, goe to the hand, where after each of them hath bestowed what was requisite on the muscles of the hand, they are wasted into other five smal portions, of which these which are from that portion which descends without the ring, send two sprigs to the little, two to the fore, & one to the middle finger; but these which come from that which passes under the ring, by such a distribution communicates it self to other fingers, as two sprigs to the thumb, two to the fore and one to the middle finger. The sixth the lowest and last runs between the skin and fleshy pannicle, by the inner protuberation of the arm, and then is spent upon the skin of the Cubit.

CHAP. XXV.

The description of the bone of the Arm, and the Muscles which move it.

Because we cannot perfectly demonstrate the originall of the muscles of the arm, (especially of the two arm muscles) not knowing the description of this bone; first therefore we will describe it, then return to the originall of the muscles arising from thence. The bone of the arm is the greatest of all the bones in the body, except the Thigh-bone; it is round, hollow and filled with marrow, with a great Appendix or head on the top thereof, having

The greatnesse and figure. The Appendix of the Arm. The processe of the arm.

an indifferent neck, to which it is knit by *Symphysis*, for appendices are no otherwise united to their bones. In the lower part thereof it hath two processe, or protuberations, one on the fore side, another on the hind, between which swellings there is a cavity like to half the compass of a wheel, about which the cubit is moved. The extremities of this cavity ends in two holes, of which one is the more externall, the other more internall: these cavities receive the heads of the cubit, that is, the fore, or internall receives the fore processe when the arm is bended inwards, but the externall or hinder the exterior as it is extended.

For the head of the arm it hath a double connexion, the one with its own neck by *Symphysis*; that is, a naturall union of the bones without any motion; the other with the slightly engraven cavity of the shoulder-blade, which we call *Glene*, by that kind of articulation which is called *Arthrodia*; this connexion is made firm and stable by the muscles descending into the arm from the shoulder-blade, as also by the proper ligaments descending from the circle and brow of the cavity of the *Acromion* and *Coracoïdes* to this head of the arm; this same head of the arm is, as it were, more cleft and open on the inner side, than on the fore side, that so it may give way to one of the ligaments coming from the shoulder-blade to the muscle *Biceps*. Forasmuch as belongs to the lower end of the bone of the arm (which we said hath two processe) we may say that it is fastned to the bones of the cubit by two sorts of articulation; that is, by *Ginglymos* with the Ell or proper bone of the cubit, and by *Arthrodia* with the *Radius* or wand, which in a lightly engraven cavity receives the fore processe of the arm, and is turned about it for the motion of the hand. The hinder processe is chiefly added for the safety and preservation of the veins, arteries and nerves.

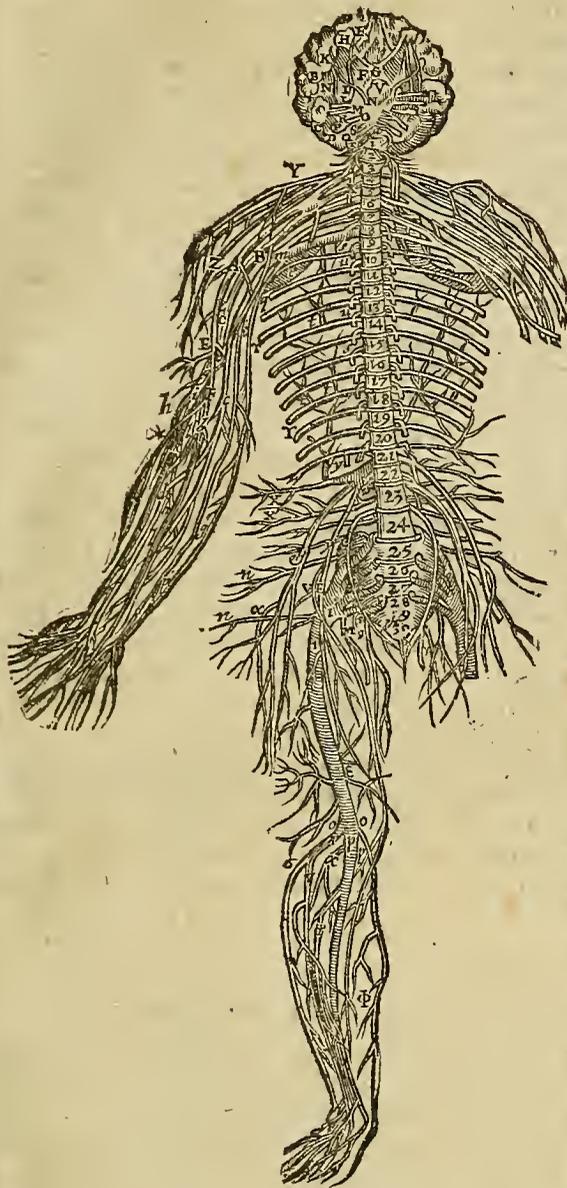

The figure of the arm.

These things thus shown, it is worth our labour to know the figure of the arm it self, as it lies between the forementioned appendices and processe; that in the case of a fracture, we may know how conveniently to restore it; therefore first we must understand, that this bone is somewhat bended and hollowed on the inside under the cleft of the head thereof, but bunching out on the out and fore side.

The 8 muscles thereof.

Wherefore seeing it must be moveable forwards and backwards, upwards and downwards, nature for the performance of so many motions hath furnished it with eight muscles, which are six proper and two common with the shoulder-blade. Of which number two move it forwards, two backwards, two upwards and downwards. Which must not be understood so, as that these two muscles should move it directly forwards inclining neither upwards, nor downwards; and the other two should move it so upwards, as it should incline neither forward nor backwards; but thus, that it cannot be moved neither to this nor that part unlesse by the help and proper action of this, or that muscle. Thus therefore if the pectorall with his associate perform their duty or action, the arm is alwaies moved for wards, as it is lifted up by the action of the *Deltoides* and his companion, and so of the rest.

Table 24. sheweth the brain together with the After-brain, the spinall marrow and the nerves of the whole body.

- A, That part of the brain that is next the nostrils.
- B, That part which is at the side of the ventricles.
- C, The back part of the brain.
- D, The *Cerebellum* or After-brain.
- E, The mamillary proceffe in the right side.
- F, The originall of the optick nerve.
- G, Their conjunctions.
- H, The coat into which the optick nerve is extended.
- I, The second pair of the sinews of the brain.
- K, The lesser root of the third conjugation.
- L, The thick root of the same conjugation according to the common opinion.
- M, The fourth conjugation of the sinews.
- N, The lesser root of the fifth pair.
- O, The bigger root of the same pair.
- P, The small membrane of the ear which they call the *Tympany*.
- Q, The lower branch of the bigger root of the fifth conjugation.
- S, The sixth pair of sinews.
- T, The seventh pair.
- V, The beginning of the spinall marrow out of the middle of the basis of the brain.
- X, The right sinew of the midriffe cut off.
- Z, A branch from the fifth pair creeping to the top of the shoulder.
- Z, The first nerve of the arms from whence there goeth a branch to the skin.
- A, The second nerve of the arm, and a branch thereof from into the first muscle of the cubit.
- B, The third nerve of the arm and a branch going to the skin on the outside.
- C, A branch from the third nerve to the second muscle of the Cubit.
- D, The congresse or meeting of the second nerve with the third.
- E, A small branch from the third nerve to the second muscle of the *Radius*.
- F, The distribution of the second nerve into two branches.
- * The lesser branch of this division leaghtned out to the skin as far as the thumb.
- a, The place of the spinall marrow where it issueth out of the brain 1, 2, 3. &c. Thirty pair of nerves arising from the spinall marrow are here noted by their Char, that is to say, 7. of the neck, 12. of the Chest, 5. of the loins, and 6. of the holy-bone.
- b, The thickest branch of the 2 nerve divided into 2 parts.

z, Branches of the 3 nerve sprinkled here and there.
 d, Nerves from the third pair to the thumb, the fore finger and the middle finger.
 ee, The 4 nerve of the arm. f, The passage hereof through the inside of the shoulder.
 g, A tripartition of this branch where it toucheth the cubit. bb, A branch distributed from the 4 nerve to the outward skin of the cubit. z, the upper branch of the division of the 4 nerve. kk, A branch of i, reaching to the outside of the hand. ll, the lower branch of the division of the 4 nerve passing through the backside of the cubit. m, the fifth nerve of the arm. n, branches of this nerve dispersed here and there. oo, A branch of the 5 nerve reaching to the inside of the hand and the fingers. p, A furcle of the branch o, derived to the outside of the hand and the fingers. qq, the 6 nerve of the arm and the course thereof under the skin. rr, the intercostall nerves there cut off where they are together with the ribs reflected forward. ss, branches on each side running backward. tt, nerves attaining unto the chest. uu, the commixtion of the nerves, rr, with the descending branch of the 6. conjugation of the brain. xx, nerves from the loins led unto this place. y, A branch going to the recticle here cut off. z, A nerve reaching to the 1 muscle of the thigh. o, the 1 nerves of the leg. aβ, A furcle of the former nerve derived to the skin at a, and inserted into the muscles at β γ, the 2 nerve of the leg. βββ, A nerve from the former, allowed unto the skin as low as the foot, and passing along the inside of the leg. ε, a branch of the 2 nerve running unto the muscles. ζ, the 3. nerve of the leg. η, a furcle thereof unto the skin. θ, another furcle unto the muscles. ι, the 4. nerve of the leg. κκ, the anterior propagations of the nerves proceeding from the holy-bone. λ, the end of the spinall marrow. μ, a branch from the 4. nerve inserted into the muscles arising from the *Coxendix* or hip bone. ν, another branch going to the skin of the thigh on the backside. ξ, a propagation derived to the 4. muscle of the leg and to the skin of the knee. oo, nerves attaining to the heads of the muscles of the foot. ωω, the division of the 4. crural nerve into two trunks σ, a branch from the trunk π, dispersed into the outward skin of the leg. τ, a furcle of the trunk π, derived to the muscles. υ, another furcle to the skin of the leg on the fore side. φ, a branch of the trunk ρ, to the skin of the inside of the leg and of the foot. χ, a furcle of the trunk ρ, to the hindmost skin of the leg. ψ, a branch of the whole trunk ρ, led along to the forward part of the leg and the foot. ω, the descent of the trunk ρ, into the foot.

But to come to the originall and infertion of these muscles; the one of these two which move the arm forwards called by reason of his originall, the *Pectorall*. arising from more than
 The originall and infertion of the pectoral muscle.

than half of the Collar bone, and almost all the *Sternum*, and the 6, 7, and 8. rib, goes up and fastens it selfe to the *Coracoïdes*, by a membrane or a membranous tendon sufficiently strong (for which cause it is said to be common to the shoulder and arm) and it goes into the arm between the muscles *Deltoides* and *Biceps* with a strong tendon composed of fibers crossing each other, of which some descend from the Collar-bone and the upper part of the *Sternum*, others ascend from the lower originall hereof; that is, from the 6, 7, and 8 ribs: and although the action of this muscle be diverse, by reason of the diversity of its fibers arising from divers places, yet alwaies it drawes the arm forwards, whether it be moved upwards, downwards, or to the Breast; the other which is his companion descends from the whole lip or brow of the sinous or hollow part of the blade, which it fills in the forepart of the arm neer the head thereof. For the two *Levatores*, or the lifters up of the arm, the first named *Deltoides* descends from almost halfe the clavicle, the process *Acromion* and all the spine of the shoulder-blade into the foreside of the arm the bredth of four fingers below the joint. It hath divers actions according to the diversity of the fibers, as also every muscle hath; yet howsoever it is contracted, whether by the fibers from the clavicle alone, or by the spinall alone, or by both at once, it alwaies lifts and heaves the arm upwards. The other which is his associate descends from the gibbous part of the shoulder-blade, contained between the upper rib thereof, and the spine between the processes *Acromion* and *Coracoïdes*, to the neck of the arm; and this we will call the *Epomis* or *Scapularis*; that is, the shoulder muscle. But the first and larger of the two muscles, which draw the arm backwards, arises from the greatest part of the utter lip of the gibbous part of the shoulder-blade, which is under the spine thereof, and lying upon the blade it self, it goes into the hind part of the arm above the neck thereof. The other which is contiguous to it and his partner in working, but lesser, passes from the upper and exterior part of the lower rib of the shoulder-blade, and thence as it were in some sort extending it self upon the gibbous part thereof neer unto that rib, it goes into the arm. This muscle seems to be the same with the former, being fleshy without even above the top of the shoulder. One and the lesser of these two which draw downwards, enters out from the streight line of the lower rib of the blade, and goes into the lower part of the arm about the neck thereof. The other called the *Latissimus* or broadest, ascends from the spines of the holy-bone, of the loins, and often also from the nine lower of the chest, by the lower corner of the shoulder-blade into which is inserted by a membranous tendon, as also it is into the inner part of the arm neer unto neck by another strong tendon; whereupon this muscle is called a common muscle of the shoulder and arm. But when this muscle happens to be wounded, the arm cannot easily be stretched forth, or lifted up.

The *Deltoides*.

The *Epomis* or
Scapularis.

CHAP. XXVI.

The description of the bones of the Cubit and the muscles moving them.

After these muscles, follow those which bend and extend the cubit, but because their insertion cannot be fitly demonstrated, unlesse the bones of the cubit be first described; therefore first of all we will delineate the bones themselves. But verily lest this doubtful word cubit should cause obscurity; first we must note, that it hath a threefold signification, for oftentimes it is used for all that part of the hand which lies between the arm and wrist, oft-times for the lower bone of this part, sometimes for the upper part of this bone which is turned within the orb or cavity of the arm (no otherwise than a cord in the wheel of a Pulley) and this is called the *Olecranon*. Here truly we use this word Cubit in the first signification. Wherefore we say the cubit is composed of two bones, the one of which we call the *Radius* or wand, or the lesser *Focile* of the arm; the other we properly call the Cubit or El. These two bones stick together at their ends being firmly bound together by strong ligaments; but the middle parts of them are a pretty way distant from each other, and chiefly towards their lower ends, for the better situation and passage of the muscles and vessels from the inner side to the exterior, as shall be shewed in sit place. The wand hath two *Epiphyses* or Appendices, the one at the upper end, the other at the lower. The upper is round and hollowed on the surface like a basin, it receives the fore proceffe of the bone of the arm, bound to the same by strong ligaments, descending as well from that proceffe of the arm, as the *Olecranon* into the circumjacent parts of this appendix of the wand. This connexion is made for this use, that we may turn our hand upwards and downwards by the cubit turned and twined about this proceffe. But the lower appendix of this wand is hollowed on the inside that so it might more commodiously receive the bones of the wrist, but gibbous without, that it might be safer; now this wand is softer and thicker at the lower end, but lesser and harder above, where on the inside it hath a swelling out, whereby to receive the muscle *Biceps*, besides on the outside of the middle thereof it is somewhat gibbous and round, so to become more safe from the injuries of external bodies; but it is hollowed, or bended on the inside for the better taking and holding any thing in the hand. But that side which lies next to the El is flatted for the fitter originall and seat of the muscles; lastly, it is seated upon the bone of the Cubit, or El, just against the thumb.

by the Cubit.

What the
Olecranon is.
The 2 bones of
the Cubit.

The two Ap-
pendices of the
wand.

The figure and
sit of the
wand.

But

But the *Ell*, or bone of the cubit properly and particularly so called, hath in like manner two appendices, the one above, the other beneath. The upper which also is the greater, is fitted to the orb of the arm in which it goes to and again for the extension and bending of the arm, no otherwise than a rope runs in a pulley but that it turns not absolutely and perfectly round, which is caused by the two processes of unequal bigness, the which are therefore stayed in the holes or cavities of the bone of the arm, the greater proceſſe which we called *Olecranon* is letted by the exterior hole that so the extension of the arm can be no further, but the lesser proceſſe by the inner hole, makes the bending thereof the lesse perfect. The composition of these bones is by *Ginglymos*, and it is strengthened not only by common ligaments coming from the muscles, which move the bones themselves, but also by proper ligaments descending from the processes of the arm and the lips of the holes and cavities standing about the appendix of the cubit. The other lower and lesser appendix is in some sort hollow on the inside for the fitter receiving the bones of the wrist, but the outside is round and ends in a point, whence it is called by the Greeks *Styloides*. But now this *Ell* (contrary in this to the wand) is thicker towards the arm, but slenderer towards the wrist. And besides in the thicker part thereof it is hollowed or bended towards the inside, and in the same place is gibbous or bunching forth on the outside; but it is round and straight, unless on that side which lies next the wand, for the rest, it is hollow and full of marrow like the wand. The site of the *Radius* or wand is oblique, but that of the cubit or *Ell* is right, that the arm might be the better and more easily moved; because the motion by which the arm is extended and bended is according to a right line, but that by which the inside of the hand is turned upwards and downwards, is performed obliquely and circularly. Wherefore it was expedient that the wand should be oblique, and the cubit straight; for the cubit-bone is appointed for to extend and bend the arm, but the wand to perform the wheeling and turning about thereof; and this is the cause that it was fitting there should be a different connexion of these bones with the arm. These things were fitting to be spoken concerning the nature of these bones, that in the cure of fractures we may work the more safely and happily, taking indication from that which is agreeable to nature: wherefore now it remains that we come to the description of the muscles which are seated in the arm, the cubit-bone, or *Ell*. These are four in number, two extending it, and two bending it. The first of the benders is called *Biceps*, by reason of its two heads, the one whereof descends from the *Coracoïdes*, that other from the lip of the cavity of the shoulder-blade by the fissure or cleft of the head of the bone of the arm. These two heads under the neck of this arm becoming fleshy, are firmly united at the belly and midst of the arm, and thus united are at the length implanted by a strong tendon to the inner protuberation of the wand. The other is called the *Brachialis*, by reason of the strait coherence thereof with the bone of the arm; this fastned under the *Biceps* descends obliquely on the back and upper part of the bone of the arm into the top of the wand and the inner side of the *Ell*. But the first of the extenders is called the *longus* or long muscle, this descends from the lower rib of the shoulder, and cleaving to the bone of the arm goes thither (fastned and as it were alwaies most straitly joined with his fellow muscle, specially near the cubit) where you shall presently hear. The other termed the *Brevis* or short Muscle, being the companion of the long, descends on the hind part of the neck of the bone of the arm, as it were growing to, and lying under the former long muscle, so that making one common broad tendon outwardly fleshy, inwardly nervous, they are inserted into the *Olecranon*, so by mutual assistance to extend the cubit.

CHAP. XXVII.

The Description of the Bones of the Wrist, Afterwrist and Fingers.

WE said before that the Hand taken more particularly and properly, is divided into the Wrist, Afterwrist, and Fingers, and that the hand in this signification is bounded by the ends of the bones of the cubit and fingers. All the parts of the wrist, which it hath common with the afterwrist, have been already also plentifully explained, this only remains to be noted, that the skin as well of the hands as of the feet, is of a middle nature between pure flesh and pure skin, no otherwise than that which covers the forehead, but that this which covers the palms of the hands and soles of the feet is unmoveable; but it is most thick, especially on the feet, lest it should be easily offended by continuall going. Besides the common parts, the wrist is composed of eight small bones mutually knit together in a certain order, and by *Diarthrosis* with the two bones of the Cubit, but mutually and amongst themselves by *Synarthrosis*, by interposition of gristles and ligaments as well common, that is, coming from the muscles, as proper, descending alwaies from the upper to the lower. But these same bones are some lesse than other some; besides, they are hard and without marrow, gibbous on the outside for the security and comlineſſe of the hand, but hollow on the inside for to give way to the tendons going into the fingers. These bones are disposed in two ranks.

What the Hand properly so called is.

The first rank contains only three, but the second five. The three of the first rank are thus arrayed, or placed, that one of them may receive the Appendix *Styloides*, of the cubit; the other the Ell and the wand together, and the third may be received by the wand. But three of the five bones of the second order sustain the four bones of the afterwrist and are knit to the same by *Synarthrosis*, after which manner of connexion they are joined to the bones of the first rank; the fourth sustains the first bone of the thumb, to which also it is coarticulate by *Synarthrosis*; the fifth and last is seated on the inside against the Ell, chiefly above that bone of the first order, which receives the Appendix *Styloides* of the cubit, this is the least and weakest of them all by reason of its gristly substance, which makes the ring with certain ligaments running from one of the inner sides of the wrist to the other.

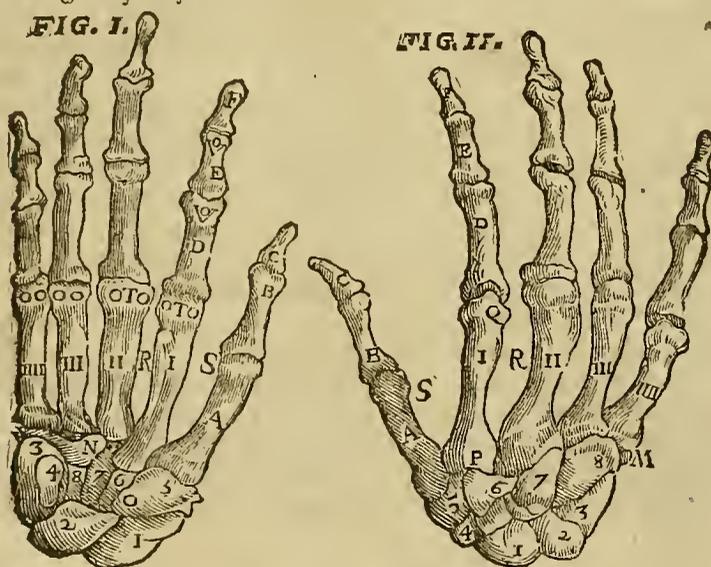

What the *Anulus* or ring is.

This ring is placed there, as well for the preservation of the sinews, veins, and arteries passing under it (left when we lean upon our hand or wrist, these parts should be hurt by compression) as also for the commodity of the action of the muscles bending the finger, which in the performance of their action and the contracting themselves might deform the hand by their passing forth of the cavity of the wrist. For what attraction soever is made by strings, if it be free and not hindered, is according to a straight line.

The bones of the Afterwrist.

Now follow the bones of the second part of the hand, or of the afterwrist. These are four in number, gibbous without, but arched within, or hollow in the middle; for hence is the palm of the hand, or certainly the greater part thereof; their ends next the fingers are somewhat remote from each other, that in these clefts the muscles *Interossea* might find a place and seat. But these ends have each an Appendix, as you may perceive in the Skeleton of a child. But you must note that by the first bone of the wrist or afterwrist, we mean that which is in the fore-side of the hand, that is to say, that in the wrist which lies under the thumb, and that in the afterwrist, which is seated under the fore finger, as these which keep in order the fingers which exceed the rest in necessity and dignity.

The Figure of the bones of the Hand. The 1. shews the inside of the right hand, and the 2. shews the back side of the same.

The Charact. 1, 2, 3, 4, 5, 6, 7, 8. shew the eight bones of the wrist.

A, 1, 2. The first bone of the Afterwrist lying under the thumb.

I. II. III. IIII. The 4 other bones of the Afterwrist annexed to the fingers.

B, C, The two bones of the thumb.

D, E, F. 1, 2. The 3 bones of the forefinger which are the same in the other fingers.

M, 1, 2. A little bone sometimes fastned outwardly at the joint of the eight bone of the wrist.

N, 1. A proesse of the eight bone of the wrist, swelling out into the ball of the hand.

O, 1. A proesse of the fift bone of the wrist, from which a ligament proceeds.

P, 2. An appendix of the bones of the wrist, by which they are articulated to the afterwrist.

Q, 2. Another Appendix which with its head entreth into the cavity of the finger.

R, 1, 2. The space between the bones of the afterwrist.

S, 1, 2. Two little seed-bones set on the inside and outside of the first joint.

T, 1. Two seed-bone in the first of the four fingers.

VV, 1. One seed-bone in the second and third joint of the fingers.

The bones of the fingers.

After these follow the fifteen bones of the fingers; that is, three in each, which are hollow and fistulous, full of a thin and liquid marrow, and not of grosse and thick, as in the arm and thigh. They are outwardly gibbous, but inwardly hollow and flat for the fitter seat of the tendons ascending alongst the fingers on the inside even to the upper joint. The which that nature might the better strengthen and preserve, it hath produced from the lips of the inner cavities of these bones a membranous and strong ligament, which running overthwart from one side to the other doth so frailty close the tendons to their bones, that they cannot goe forth of their places, or incline to either side. They are connexed on the outside, that they might be more fit to hold any thing. But for the first bones of the 4 fingers and thumb, four are joined together with so many bones of the afterwrist by *Synarthrosis*, for the bones of the afterwrist are moved by no manifest motion; the fift is knit to the second rank of the bones of the wrist, therefore that bone cannot be attributed to the after-

afterwrist, as some have written, seeing it hath manifest motion and is knit by *Diarthrosis*, but the bones of the afterwrist are only fastned by *Synarthrosis*. For the second and third rank of bones of the fingers, they are knit the second to the first, and the third to the second by *Diarthrosis* and *Arthrodia*, because besides the manifest motion they have, they receive each other by a superficial cavity, as those of the first rank, the bones of the afterwrist, and those of the second rank, them of the first; those of the third them of the second. And all the bones of the fingers are larger and thicker at their basis, but smaller towards the ends, and they are bound by ligaments especially proper, which (as we said formerly) descend from the first to the second; so that the last bones seeing they have not to whom to communicate their nerve, make and produce nails thereof: Wherefore the nails are generated by the fibers of the ligaments, and the excrement of the tendons which are terminated at the bottom of the nails. Now remain the *Ossa Sesamoidea*, or seed-bones: these are 19 in number in the inner joints of each of the hands, and as many in each foot, viz. two in the first joint of the four fingers and in the second of the thumb, and one in each of the rest. For the inner side of the joints, you may for the most part observe one in each of them; yet in the second joint of the thumb there be two, above the two tendons, which are somewhat gristly.

They are made for this use, that they firm and strengthen the joints, so that the bones of the fingers may not be turned awry, or thrust forth of their places by strong and violent motions, as it sometimes happens in the whirlebone of the knee. They are called *Sesamoidea* from the resemblance they have to the seed of *Sesamum* which is somewhat long and flat.

Whence the nails are generated.

The *Ossa Sesamoidea*, or seed-bones.

Their use.

CHAP. XXVIII.

Of the muscles which seated in the cubit move the Wand and with it the Hand.

Now must we describe the muscles of the formerly described parts; that is, those which are seated in the cubit, which are carryed to the inside of the hand, and those which are called the *Interosses*. Now the muscles of the cubit are 14, seven externall and seven internall; two of the seven externall doe primarily twine or turn up the Wand, and secondarily or by accident turn the palm of the hand upwards, whereupon they have called them *Supinatores* or turners up of the hand; two extend the wrist, whereupon they are named *Carpitenses* or the wrist-extendors; two the fingers, whence they are stiled *Digitumtenses* or fingerstretchers; to conclude, the seventh and last is termed *Abductor* or *Obliquator externus*. The first of the two *Supinatores* is called the Long, or Longest, because it descends from the outside of the arm above the processes thereof, and is inserted by a round and strong tendon into the lower Appendix. The other descends obliquely from the outward and upper proceffe of the arm, and is inserted at the third part of the wand by a membranous and fleshy tendon before and on the inside thereof. The upper of the two extendors of the wrist, descending above the wand from the external and upper proceffe of the arm, is inserted by two tendons into the first and second bone of the afterwrist, which sustain the fore and middle fingers.

The muscles of the cubit.

The *Supinatores*.

The *Carpitenses*.

The *Digitumtenses*.

The *Obliquator externus*.

The first of the *Supinatores*.

The second.

The upper of the *Carpitenses*.

The lower.

The other and lower, descending from the same place as the former, above the cubit is inserted into the fourth bone of the afterwrist which bears up the little finger. These muscles whilest they move alone, that is, each with his Antagonist, to wit, the wrist-benders, they move obliquely upwards or downwards, the whole hand properly so called. The first and greater of the extendors of the fingers, or finger-stretchers arising from the *Olecranon*, or bone of the cubit, descends superficially between the two bones of the cubit even to the wrist, in which place it is divided into four tendons, which passing under the ring seated there end (each distinguished by a common ligament above the bone of the afterwrist) in the last joints of the four fingers, adhering nevertheless firmly to the bones, which are above these joints.

The greater of the *Digitumtenses*.

The other which is the lesser, arising almost in the middle of the wand, goes obliquely to the thumb into which it is inserted by two tendons; the one thicker which is inserted into the root thereof, and draws it from the other fingers; the other slenderer continued even to the upper joint thereof, and by its action extending the thumb.

The lesser.

The seventh which is the *Abductor* or *Obliquator*, is seated at the hind part of the hand; that is, towards the little finger; we have often found this divided in two, yea verily we have found it triside, or divided into 3. this year in three or four dead bodies, one portion thereof went to the lower side of the ring-finger with two Tendons, the other in like manner to the middle and forefingers, and the third to the thumb.

The *Obliquator* or *Abductor externus*.

And for all that it is thus divided, yet some have taken and accounted it for one muscle, because it hath one originall and action, which is to draw the fingers backwards, some have added to this the extender of the thumb by reason of their common originall; and thus of four muscles they have made one divided into seven tendons, distributed, as is formerly shewed. But when the *Obliquator* of the ring-finger is wanting, as it often happens, the extender of the finger supplies that defect by certain productions of tendinous strings. But some also have written, that this muscle which we said hath seven tendons,

is only a production of the deep fore muscle, which should be sent through the space between the bones of the cubit; yet I had rather make it a muscle of it self, by reason of its strait adhesion with the bones of the arm and wand. And let thus much suffice for the external muscles of the cubit, which you may comprehend in the number of seven, as we have done; or in six, if you take away one of the 4. or in nine, if you had rather resolve it into 4. with *Galens*; or in eight, if you divide this muscle only into three. For in very deed the *Abductor* or *Obliquator* of the ring-finger is not often found in men.

The muscles of the inner part of the cubit.

Now must we come to the inner muscles of the cubit, the first of which compasses the skin of the palme of the hand, whence it is called the *Palmaris*. The second and third joined by the communion of their action turn down or prone the wand, and consequently the hand, so that the palme looks towards the feet, whereupon they are called *Pronatores*.

The *Palmaris*.

The 4. and 5. joined also in affinity of action bend the wrist, wherefore they are named *Carpiflexores*, wrist-benders. The sixth and seventh are appointed to bend the first, second, and third joints of the fingers, wherefore they are termed *Digitumflexores*, *Fingerbenders*. For their originall; the *Palmaris*, the least and uppermost of them all, descends fleshy from the hind proceffe of the inner arm, and a little after ending in a long and slender tendon, it is spent in the skin of the palm of the hand even to the roots of the fingers. For it was necessary that this skin should straitly cohere with the subjacent parts, not only for the fitter taking or comprehension of any thing, lest that skin in holding should be wrinckled and drawn away from the palme and fingers, and so be an impediment; but besides that the hand might have a more exact sense to distinguish of hot, cold, moist, dry, smooth, equal, rough, soft, hard, great, little, and such other qualities. Then follow the two *Pronatores*, of which one called the round, comes obliquely from the inner side of the hind proceffe of the arm almost to the middle of the wand, to which it adheres by a membranous and fleshy tendon, even to the place appointed for insertion. The other square three or four fingers broad, yet somewhat slender, seated within under all the muscles which descend on the inside to the wrist or fingers, upon the ends of the bones of the cubit, ascends transverse from below the *Ell*, unto the top of the wand, where it ends in a membranous tendon. Both the *Carpiflexores*, or wrist-benders, arise from the hind, but inner proceffe, and descend obliquely, (the one more, or lesse than the other) the one alongst the *Ell*, but the other alongst the wand; and that which descends alongst the *Ell*, is inserted into the eight bone of the wrist, which we said made part of the ring; the other which follows the wand is inserted with his greater part into the bone of the wrist, and with the rest into the first bone of the after-wrist which sustains the fore finger.

The *Pronatores*.

The *Carpiflexores*.

The *Digitumflexores*.

The *Sublimis* *Digitumflexor*.

Now remain the *Digitumflexores*, or *Fingerbenders*, which because they lye upon one another, the upper is called the *Sublimis*, but the lower the *Profundus*. The *Sublimis* or upper, arising from the inner part of the hind proceffe of the arm, and from the upper parts of the *Ell* and wand, descends between these two bones of the cubit even to the wrist and ring; divided into 4. tendons it is inserted into the second dearticulation of the four fingers, which it bends by the force of this his proper insertion; as also the first, as well by the power of the common ligament, as by certain fibers coming from it, which it sends thither by the way in its passage. But these 4. tendons neer unto this their insertion are divided into two, so to give passage and add strength to the tendons of the deep muscles descending into the third and last joint of the fingers.

The *profundus* *Digitumflexor*.

But this same *Profundus* or deep muscle arising from the upper and inner parts of the *Ell* and wand, descends between these two bones under the *Sublimis*, also undivided even to the wrist, where it is divided into 5. Tendons which it brings forth under the common ligament, and the divisions of the tendons of the *Sublimis* even to the last joint of the fingers, which they bend, by this their proper insertion, as also the bones of the first and second joints of the fingers by the means of the common ligament and fibrous productions which they bestow upon them by the way. Besides these forementioned there is seen also a certain membranous ligament which engirts the tendons in the compasse of the fingers.

CHAP. XXIX.

Of the Muscles of the inside of the hand.

The number of the muscles of the inside of the hand.

The muscles of the inside of the hand are 7 in number; the first is called *Thenar*, because it makes the greater part of the *Palme*; the second from the site is called the *Hypothenar*; the third the externall *Abductor* of the thumb. The four other are called by reason of their figure the *Lumbrici* or wormy muscles, or the *Abductores*, or *Drawers* of the four fingers to the thumb. Now the first called

The *Thenar*.

Thenar, thicker than the rest, arises from all the bones of the afterwrist, taking its beginning from that bone which bears up the ring finger, whence ascending alongst the *Vital* line even to the end thereof at the first bone of the afterwrist sustaining the fore finger, and it is at length inserted into the last joint of the thumb by the longest fibers, but by the middle

middle and shortest fibers almost into all the inner part of the first bones of two joints, and by reason of this, the thumb is drawn to the other fingers, and from them again by his lower originall.

Some divide this muscle into three, by reason of his divers actions, making the first to arise from the root of the bone of the afterwrist which bears up the ring finger; but the other from that middle bone of the afterwrist which sustains the middle finger; but of the third, from the upper end of that bone which underprops the fore finger, and that the insertion of them all, is, as we formerly mentioned. But the former opinion likes me better, both for shunning confusion, and abbreviating the doctrine of the number of muscles.

The *Hypothenar* arises from the fourth bone of the afterwrist, and that bone of the wrist which sustains it, and then with its longest fibers, it is inserted into the second joint of the ring finger, and by the shortest into the first, through which occasion, as also in respect of its twofold action, some have divided it into two, that the one of them might lead it from the rest, and the other might draw it to the thumb.

The third the externall *Abductor* of the thumb, descends from the first bone of the afterwrist, into the first and second joint of the thumb; wherefore some have divided it into two. The *Lumbrici*, or four externall *Abductores* of the fore fingers arise from a membrane, investing and binding together the tendons of the *Digitumflexores*, or fingerbenders, and at length on the sides towards the thumb even by a small tendon, running even to the second joint of the four fingers.

Now the *InterosSES* of the afterwrist, remain to be spoken of; these are six, two in each of the spaces between the fingers, one internall, the other externall, of which the internall descending with oblique fibers from the side of the first bone of the afterwrist, goes also into the sides of the fingers, that so it may the more closely bind together the bones of the afterwrist, whose action is manifested when we thrust our fingers into a strait glove, or when we bend our hand. Some think that it helps also the drawing of the fingers towards the thumb. The externall ascends also by oblique fibers from the sides of the second bone of the afterwrist, to the first joints of the fingers, intersecting the internall which we now described after the manner of the letter X, for to extend the palm of the hand, and help the drawing away of the fingers from the thumb.

Here concluding the description of the muscles of the whole hand taken in generall, you shall note that they are 39. in number, that is, eight appointed to move the arm; four set to move the cubit in generall; seven seated on the outside of the cubit, and as many on the inside in the same cubit, moving the wand, and with it the hand; seven on the inside of the hand: and lastly, the six *InterosSES*. Some encrease this number, saying, there are nine on the externall part of the cubit, and eleven on the inside of the hand.

CHAP. XXX.

A Description of the Leg taken in generall.

After the hand follows the description of the Leg. Wherefore to take away all doubtfulnesse, we will first define the leg; then divide it into the parts more and lesse compound; thirdly, we will prosecute all things common to all these parts; fourthly, those which are peculiar to each; and then, God willing, we will give an end to our Anatomy.

Now this word *Crus*, or leg, is used two manner of wayes, that is, either generally or specially, and specially again after two sorts, that is, either absolutely and simply so, or with an adjunct. It is simply taken for all that which is between the knee and the foot. But with an adjunct for the greater bone thereof. But the leg taken in generall, is the instrument of going, containing all whatsoever is from the hips, to the very ends of the toes. It is divided into three great parts, that is to say, the thigh, the leg, or shank, and the foot. By the thigh we mean that which lies between the hip and the knee. By the leg, properly so called, or shank, that which is contained between the knee and the foot. By the foot all from thence to the ends of the toes.

Again, they divide the foot into three parts; that is, the *Tarsus* or instep, the *Pedion* or top of the foot, and the *Digitum pedum*, or toes. We understand by the instep, that which is contained in the first seven bones, which answers in proportion to the wrist of the hand. By the top of the foot, that which is comprehended in the five following bones, which is answerable to the afterwrist. That which remains, we call the toes. But because all these parts have other common and proper parts, we will only follow the distribution of the veins, arteries, and nerves; seeing we have sufficiently explained the rest, when we described the containing parts of the body in generall.

The *Hypothenar*.

The externall *Abductor* of the thumb.
The *Lumbrici*.

The *InterosSES*.

The toes.

C H A P. XXXI.

A Description of the Crural vein.

The beginning
of the Crural
vein.
The two bran-
ches thereof.

The crural vein begins then, when the hollow vein passing forth of the *Peritoneum*, and stretched to the hanch bone, and the sides of the *Pubis* in the groin, is first divided into two large branches, the one of which descends on the inside, alongst the bones of the whole leg, together with the artery and nerve; the other runs down outwardly and superficially alongst the leg, between the fat lying under the skin, and the muscles even to the foot, and is spent in the skin thereof. This because it is alwaies apparent and manifest, is called properly by the Greeks *Sapheia* but commonly *Saphena*.

By what veins,
the matter cau-
sing those tu-
mors called
Bubones flow
down.

This vein by the way presently at its originall is divided into two branches, the one internall, the other externall; of which the internall is spent upon the *Bubones*, and other glandules of that place and the skin, and by this branch come the defluxions called *Bubones*; the other branch is wasted in the fore and utter skin of the upper part of the thigh; then a little lower, that is, about the bredth of three or four fingers, it is gathered again into one branch made of many little ones, which is spent in the fore and hind skin of this thigh. Thirdly, a little below the middle of the thigh it is again divided into two other branches, of which the one goes into the skin on the foreside, and the other on the hindside. Fourthly, it is distributed by two other small sprigs into the skin, on the fore and hind part of the knee; whith oftentimes are not found, especially when the *Poplitea* or ham vein, is somewhat larger than ordinary. Fifthly, a little below the knee, it produces two other branches, lying upon each other in their passage out into the fore and hind skin of that place. You must note, that branch which runs into the skin of the hind part, is carried by a certain other sprig, which it produces, into a branch of the *Poplitea* passing forth of the two twin muscles. Sixtly, in the bigger part of the calf of the leg, it is divided into two other branches, which in like manner are distributed into the skin, as well in the foreside as the backside of the leg.

Where and in
what diseases,
the *Sapheia*
must be open-
ned.

At length after many other divisions, which for brevity sake I omit, when it arrives at the fore and inner side of the ankle (where it is commonly opened in the diseases of the parts below the midriffe which require blood-letting) it is parted into two other branches, the lesser of which descends to the heel; the other in many sprigs is spent upon the skin of all the upper and lower part of the foot and toes.

To what pla-
ces, and by how
manifold divi-
sions the inter-
nall branch of
the crural vein
goes.

Ischiadica vena.
Muscula vena.

The second branch of this crural vein, which we said descends within together with the artery and nerve, even into the foot, is divided; first, piercing somewhat deep in, it produces four divarications; one internal descending below the original of the into *saphia* the muscle called *Obturator externus*, and into certain other external muscles. The three other run outwardly, the first towards the huckle-bone, by which the *Ischias* is made, the two other into the fore muscles of the thigh, neither are these sprigs far remote from one another. Secondly, al that branch is divided into two other branches, the one above, the other below, an artery alwaies accompanying it; the lower of which is spent upon many of the hinder muscles of the thigh ending nigh the ham. The upper, besides, that it bestows many branches upon the fore and inner muscles of the thigh; descending to the ham, it produces the *Poplitea* or ham vein, made sometimes of two branches, the one proceeding from above, and the other from below. This *Poplitea* descending by the bending of the ham, is spent one while upon the skin of the calf of the leg, another while upon the knee, otherwhiles encreased with branches of the *Sapheia*, it goes on the outside of the ankle to the skin, on the upper side of the foot, and sometimes on the lower.

Poplitea vena.

Suralis vena.

Thirdly, a little below the original of the ham vein, and under the bending of the knee, it brings forth the *Suralis*, which is bestowed upon the muscle of the *Sura*, or calf of the leg, and upon the skin of the inner side thereof, and of the foot continued sometimes even to the inner part of the great toe.

Fourthly, under the head of the hinder appendix of the bones of the leg, it produces between these two bones, another vein, which nourishing the fore muscle of the leg, is consumed upon the foot.

*Ischiadica ma-
jor.*

Fifthly and lastly, it brings forth the *Ischiadica major* or greater *Ischias*, which is divided into two branches of an unequal bignesse; the larger whereof, from his originall descending alongst the inner part of the leg bone, insinuates it self under the muscles of the calf, between this and the heel, into the sole of the foot, upon which it is wasted, divided into ten small sprigs, two for each toe; the other being the lesser descending alongst the *Perone*, or shin-bone, is consumed between it and the heel, yet sometimes it is produced, not only even to the muscle the *Abductor* of the toes, but also by five surcles, even to the fourth toe, and the sides of the middle toe.

C H A P. XXXII.

The Distribution of the Crurall Artery.

THe crurall artery arising from the same place whence the crurall vein proceeded, and descending with the internall crurall vein, is distributed as followeth.

First, into the muscle of the thigh, which spreading it self through the muscles thereof meets with the utmost *hypogastrica*, descending with the vein through the common hole of the huckle and share bone, and is joined with it.

Secondly, when it arrives at the ham, between the *Condylus* or processes of the leg, it sends two branches into the knee.

Thirdly, a little after it produces another branch, which it sends to the exterior muscles of the leg, and when it arrives at the middle of the leg, it is divided into two branches, between the twin muscles and *Soleus*, the one internall, the other externall; the internall, some surcles communicated by the way to the parts by which it passes, but specially to the joint of the ankle, stretches it self over the sole of the foot, between the lower extremity thereof and heel, whither when it arrives, it is divaricated into five surcles, of which it bestowes two on the great toe, two on the next, and one on the middle toe. The externall descending in like manner to the sole of the foot, between the *fibula* and the heel, besides other sprigs, which it may spread by the way, it produces one without on the joint of the ankle, another in the muscle, the *Abductor* of the toes, to the wrist and back of the foot. But the remainder is divided into five portions, of which two are sent to the fourth, and two to the little toe, and one to the middle.

Arteria muscula.

C H A P. XXXIII.

Of the Nerves of the Loins, Holy-bone and Thigh.

THere arise five conjugations of nerves from the loins, divided into externall and internal branches; the external are diffeminated into the *Rachite* or chin muscles; the muscles *Semispinatus* and *Sacer* and the skin lying over them. The internall are sent into the oblique ascendent and transverse muscle of the lower belly, into the *Peritoneum*, into the loin and chest muscles arising there, but after a different manner; for some are absolutely carried thither, as the nerves of the first conjugation of the loins, and oftentimes also of the second, but that sometimes they send a small sprig to the testicles, when the Costall have sent none thither; but some lower are partly distributed there, and partly sent some other way; for the greater portions first united amongst themselves, then presently with the portions of these of the holy-bone, goe into the thigh, as we shall shew in the distribution of the nerves of the holy-bone.

Now from the holy-bone, proceed six conjugations of nerves, reckoning that for the first which proceeds from the last *Vertebra* of the loins, and first of the holy-bone, and that the sixth which proceeds from the lowest part of the holy-bone, and the first of the rump; these conjugations of nerves are divided into externall and internall branches.

The lesser externall passing forth by the externall and hinder holes of the holy-bone, are distributed into the parts properly belonging thereto, to wit, the muscles and skin thereof; for every nerve by the law of nature first and alwaies yeelds to the neighbouring parts, that which is needfull, then presently to others as much as it can.

Wherefore if thou wouldst know whence each part hath his vessels at the next hand, that is, the veins, arteries, and nerves, thou must remember the site of each part, and the course of the vessels, and to consider this, that the veins and arteries as speedily and conveniently as they can, insinuate themselves into the parts, sometimes at the head or beginning, somewhiles by the middle or extremes thereof, as there is occasion.

But a nerve principally enters a muscle at the head thereof, or at least not far from thence, but never by the tail, whereby it may easily be understood by what branch of each vein, artery, and nerve, each part may have nourishment, life, and sense. The other internall branches of the foresaid conjugations goe, especially the four uppermost united from their originall with the three lowermost of the loins, into all the leg, as you shall presently hear. But the two lower are consumed upon the muscles called *Levatores Ani*, the *Sphincter* muscle of the same place; besides, upon the muscles of the yard, and neck of the bladder in men, but in women upon the neck of the womb and bladder.

For these parts admit another in their bottom from the costall nerve, being of the sixth conjugation of the brain; these thus considered, let us come to the nerves of the thigh, which (as we said) from their first originall, as it were compacted and composed of the greater portion of the three inner and lower branches of the loins, and the four upper of the holybone, are divided in the thigh into four branches, of which the first and higher descending from above the *Peritoneum*, to the little *Trochanter*, is wasted upon the inward and superficial muscles of the thigh, and the skin which covers them a little above the thigh.

The five conjugations of the nerves of the loins.

Where the testicles have their nerves.

The conjugation of the nerves proceeding through the holybone.

An Anatomical axiom.

The second, descending with the crural vein and artery by the groin, is divided into two branches like as the vein, the one internall, the other externall, of which the internall descending with the vein and arterie is sent into the inner and deep muscles of the thigh, ending above the knee. But the externall descending superficially with the *Saphæia*, even into the foot, gives branches by the way to the skin which covers it.

The third seated under these former, passing by the hole common to the share and hanch-bone, sends certain branches to the groins, to the muscles called *Obturatores*, to the *Triplices*, and sometimes to the muscles of the yard, and it ends at the midst of the thigh.

The fourth, which is the thickest, solidest and hardest of all the nerves in the body, descending wholly from the productions of the holy-bone, and descending outwardly, between the lower part of the same bone, and the *Os Ilium*, or Hanch-bone to the thigh, bestows certain sprigs to the hind muscles thereof proceeding from the protuberation of the *Ischium* or huckle-bone, and in like sort it gives othersome to the skin of the buttocks, and also to the skin covering the forementioned muscles.

A little after, it is parted into two branches descending undivided even to the bending of the knee, they both are communicated by divers fibres of the muscles of the leg; yet so as the lesser produces another branch from the rest of the portion thereof descending on the fore part of the leg, alongst the shin-bone unto the top of the foot, where it is divided into ten fibres scarce apparent to the sight, two running to each of the toes. The other greater descending in like manner in the remainder of its portion by the hind part of the leg into the sole of the foot, casts it self with the veins and arteries between the heel and leg bone, were first divided into two branches, each of which presently parted into five, send two sprigs to the sides of the toes. And these are the most notable and necessary distributions of the vessels and nerves; we purposely omit others which are infinite, and of which the knowledge is impertinent.

CHAP. XXXIV.

Of the proper parts of the Thigh.

AVING explained the common parts of the leg in generall; now we must come to the proper, beginning at the Thigh. The proper parts of the Thigh, are muscles, bones, and ligaments. But because the demonstration of the muscles is somewhat difficult, if we be ignorant of the description of the bones from whence they arise, and into which they are inserted; therefore we judge it worth our labour, first to shew the bones, and the dearticulation of these of the Thigh; beginning with these bones which are knit with the upper part of the holy-bone. And they are two in number, on each side one, commonly called the *Ossa Ilium*; each of these is composed of three bones, of which one is the upper, another the lower and anterior, and the third the middle, and after a manner the posterior. The upper by a particular name is called the *Os Ilium*, the hanch-bone, and it is the largest and biggest, having a gristly Appendix in the compass thereof, even to the connexion it hath with the other neighbouring bones, whose upper part we term the right line thereof; but the *basis*, which is adjoined to it by *Symphysis*, we call the lip or brow thereof, because it stands both somewhat out and in, after the manner of the brow. But that which lies between the *basis* and straight line we name the Rib; this same upper bone hath two hollow superficies, the one internall, the other externall. The connexion thereof by *Symphysis*, is twofold, the one with the upper part of the holy-bone; the other with that bone we called the middle, and after some sort the posterior; which taking its beginning from the narrower part of the *Os Ilium*, makes that cavity in which the head of the thigh is received; this cavity the Greeks call *Cotyle*, the Latins *Acetabulum*, and it is ended by the side of the hole common to it, and the share-bone; this middle, and in some sort posterior bone is called properly and particularly the *Os Ischii*, or huckle-bone, and contains nothing else but the forementioned cavity, but that on the hind and lower part thereof, it brings forth a proesse, which adjoins it self to the share-bone at the lower part of the common hole, in which place it appears very rough and unequal, and it is called the tuberositie of the huckle-bone, at whose extremity also it brings forth a little head somewhat resembling the proesse of the lower jaw called *Coronc*. The third bone named *Os pubis* or the share-bone, stretches it self even to the highest part of the *pecten*, where meeting with the like bone of the other side, it is united to it by *Symphysis*, after which manner also, all these three bones are united; it is reported, that this bone opens in women in their travel, yet hitherto I can find no certainty thereof.

You may perceive a manifest separation of these three bones in the *Skeleton* of a child; for in those who are of more years, the gristles which run between these connexions turn into bones.

Now follows the thigh-bone, the biggest of all the bones of the body; it is round, and so bended that it is gibbons on the exterior and forepart thereof, that so it might be the safer from

from

from externall injuries; but on the hind and inner part, it is hollow or sinuous, like to the back of an Ass, whereby the muscles might have a more commodious originall and insertion.

The figure of the Thigh-bone.

A 1, 2. The head of the thigh going into the cup of the hip-bone.

B, 2. A sinus in the head of the thigh, into which is inserted a round ligament.

C 1, 2. The conjunction of the appendix of the thigh with the bone it self.

D 1, 2, 3. The neck of the thigh.

E F The two lower heads of the thigh.

G 1, 2. The conjunction of the lower appendix.

H 1, 2. A sinus betwixt the two heads of the thigh.

K 2. A part of the lower head of the thigh, from whence the first muscle of the foot doth proceed.

L 2. Another part from whence the second and first muscles arise.

M 2. Another part to which the Tendon of the fifth muscle of the thigh is inserted.

N 1, 2. A sinus of the outward side of the head for the fourth muscle of the leg.

O 2. A sinus of the inside through which the tendons doe passe.

P 2. A protuberation at which the said tendons are reflected.

Q 2. The upper proceffe of

the thigh, and betwixt Q and D is the sinus. R 1, 2. The union of the proceffe with the thigh. S S 2. A rough line from the impression of the externall proceffes. T 1. The anterior impression of the internall proceffes, β , betwixt T and V another impression higher than the former. V. 1, 2. The fourth impression in the top of the proceffe. X 3. Four X; shew the four appendices of the thigh. Y 3. Three Y, shew the three heads of the thigh. ZZ 3. Two proceffes of the thigh. a 1. The interior proceffe of the thigh. b 1. The conjunction of the proceffe with the thigh, c c 2. A line descending obliquely from the inner proceffe. dd 2. A line running through the length of the thigh. e 2. The largeness of the thigh in this part. f 1. A roughness from which the eighth muscle issueth. g, b 5. A knob of the Whirle-bone going into the sinus marked with I, which is betwixt the heads of the thigh. i 5. A sinus fitted for the inner head of the thigh. k 5. A sinus agreeing with the externall head of the thigh. l 5. the lower asperity or roughness. m 4. The foreside of the pattell or whirle-bone rough and unequal.

That sinuous part a little below the midst thereof, is divided into two lines, the one whereof goes to the internall tuberosity, the other to the externall of the lower appendix of the same thigh. These are chiefly to be observed, because the oblique fibers of the vast muscles thence take their originall.

Besides, this bone hath two appendices in the ends thereof, as easily appears in a child's thigh; the upper appendix makes the round head of the thigh it self, which (as every other appendix) seated upon a long neck, is received in the cavity of the hanch-bone by Enarthrosis; it is stayed and fastned there by two sorts of ligaments, of which the one is common, proceeding from the muscles, which descend from above, about the neck thereof; the other is proper, which is twofold, that is, one membranous and broad, proceeding from the

The two appendices of the thigh-bone.

the whole cavity of the orb, or cup, descending about all the head of the thigh, above the neck thereof; the other thick and round, descending from the second cavity of the *Cotyle* it self, which is extended, even to the common hole at the top of the head thereof.

The two processes of the thigh-bone make the two *Trochanters*.

Besides, under this head, that bone hath two processes, the one great and thick, the other little and short.

The greater seated in the hind part, is called the great *Trochanter*; the lesser situate in the inner part, is named the little *Trochanter*.

Whence the marrow becomes partaker of sense.

But you must note, that the greater *Trochanter*, on the higher and hind part thereof, which looks towards the head of this bone, makes a certain small *sinus* or bosome, into which the twin muscles and others, whereof we shall hereafter speak, are implanted; we must also consider the multitude of holes encompassing this neck, between the head and the two *Trochanters*, which yeeld a passage to the vessels, that is, the veins, arteries, and nerves, into the marrow of the bone it self, whence the marrow it self becomes partaker of sense, especially on that part which is covered with a coat, and the bone lives and is nourished.

The other Appendix of the thigh, that is, the lower, is the greatest and thickest, rising as it were with two heads, which are divided by two cavities, the one superficial and on the fore side, whereby it receives the whirl-bone of the knee; the other deep, and on the back part, by which it receives the gristly and as it were bony ligaments, proceeding from the eminencie which is seen between the two cavities of the upper appendix of the bone of the leg, which *Hippocrates*, *lib. de fracturis*, calls in his tongue *Diaphysis*.

CHAP. XXXV.

Of the Muscles moving the thigh.

Their number.

The muscles of the thigh are just fourteen in number, that is, two bend it, whereupon they are called the *Flexores*, or benders; three extend it, whereupon they are called *Tensores*, extenders; three move it inwards, driving the knee outwards, and drawing the heel inwards, as when we crosse our legs; yet some make these three one, and call it the *Triceps*, or threeheaded muscle. Six spread it abroad, and dilate it, as happens in the act of venery.

Four of these are called *Gemini* or Twins, by reason of the similitude of their thicknesse, originall infertion and action; the two other are called *Obturatores*, because they stop the hole which is common to the share and back-bones.

The two *flexores*.

Now one of the two *Flexores*, being round, descends on the inside with fibers of an un-equall length from all the transverse processes of the loins, above the hind commissure of the hanch and share-bones, and is inferted into the little *Trochanter*; the other broader and larger from the originall passes forth of the whole lip, and inner brow of the hanch-bone, and filling the inner cavity thereof, is inferted above the forepart of the head of the thigh, into the little *Trochanter* by a thick tendon, which it with the fellow muscle lately described, produces even from the fleshy part thereof, wherefore you need to take no great pains in drawing or plucking them away.

The three *tensores*.

The three *Tensores* or extenders, make the buttocks, of which the first being the thicker, larger, and externall, arising from the rump, the holy-bone, and more than half of the exterior and hinder lip of the hanch-bone, is inferted by oblique fibers, some four fingers breadth from the great *Trochanter* at the right line, which we said, resembled an Asses back.

The second, which is the middle in bignesse and site, descends from the rest of the lip, and from the fore and outward rib of the hanch-bone, and above the midst of the bone, is inferted into the upper part of the great *Trochanter*, by a triangular infertion above the upper and exterior part thereof.

The third being lesser, shorter, and thinner, lying hid under these former, proceeds from the middle of the externall surface of the hanch-bone; and then is inferted into the greater part of the right line of the great *Trochanter*.

These three muscles have a great and large originall, but a narrow infertion, as it were by oblique fibers.

Three *Intromoventes*.

Then follow those three muscles which move the thighs inwards, straiten and crosse them, so that the knee stands forwards or outwards, but the heel is drawn inwards, as you may understand by their infertion, although some think otherwise. But these three muscles by their originall, partly fleshy, and partly membranous, arise from the upper and forepart of the circumference of the share-bone, and thence are inferted into the hind line of the huckle-bone, some higher than othersome; for the lesser and shorter stays at the roots of the little *Trochanter*, the middle descends a little deeper, the third with the longest of his fibers, descends even to the midst of the line.

This if it be so, that is, these muscles proceeding from the fore and upper part, to be inferted into the hinder line of the huckle-bone, whilst they alone perform their action, and draw the thighs together, they will turn them outwards, just so as when we put them across,

acrosse, but they will not draw one heel to another, and put the heel outwards, for such like motion is performed by the inner vast muscle of the thigh, moving the leg. Now follow the six which move the buttocks.

The movers of the buttocks.

The first, and higher of the *Quadrage mini*, or the four twiv muscles, passes forth of the commissure of the holy-bone, with the bone of the rump, or rather from the lowest extrem of the holy-bone, and thence it is inserted into the cavity of the great *Trochanter* by a tendon of a sufficient largeness.

The second proceeding from the hollow part or fissure, which is between the extremity of the huckle-bone, and the tuberosity or swelling out of the same, is inserted in like manner into the cavity of the great *Trochanter*.

The third ascends from the inner part of the swelling out of the huckle-bone, a little above, between the two *Trochanters*, into the cavity of the greater of them.

The fourth and last, the lowest and broadest of them all, proceeds from all the exterior protuberance of the huckle-bone, and thence is inserted into the great *Trochanter*, and these four muscles lie hid under the thick and more eminent part of the buttocks; wherefore that you may the better shew them, they must be turned up towards their originall.

The two *Obturatores* remain to be spoken of, that is, the internall and externall, both which arise from the circuit and circumference of the hole which they stop, which as we said is common to the share and huckle bone, but the internall ascends to the exterior root of the great *Trochanter* by the middle fissure between the upper part of the protuberancy of the huckle bone, and the spine which stands up in the hinder basis of the hanch bone.

The two Obturatores.

But the externall proceeds from the exterior cavity, and the middle space between the tuberosity of the huckle bone and cavity thereof, and is inserted into the lower part into the cavity of the great *Trochanter*, together with the *Quadrage mini*.

If you would plainly see the exterior *Obturator*, you must either cut off the beginning of the three-headed muscle, or handsomely pluck it away, and then extend it, and turn it up; the internall is easily discerned when the bladder is taken away.

CHAP. XXXVI.

Of the bones of the Leg, or Shank.

Those which would describe the muscles of the leg, ought first to describe the bones thereof, beginning at the *Rotula*, or whirle bone of the knee.

What the *Patella*, or white bone of the knee is.

This bone is grifly on the outside, and round in compass, but on the inner and middle part after some sort gibbous, but somewhat flatted at the sides, that so it may be fitlier applied to the joint of the knee, and fitted within the anterior cavity of the two appendices of the thigh, and the upper and foremost of the leg.

The use thereof is to strengthen the joint of the knee, and to hold the leg at his due extent, so that it may not be bended so far forwards, as it is backwards.

The use thereof

The bones of the leg are two, the one thicker, called by the particular and proper name, the *Os Tibie* or leg bone; the other which is lesser, is termed *Perone*, or *Fibula*, but commonly the lesser *facile*, (and in English it may be termed the shin-bone.) The thicker being hollow and marrowie, is seated in the inner part of the leg, having two processes, the one bigger, the other lesse.

What, and how many bones the leg hath.

The leg-bones

The bigger seated on the upper part of the bone, and conjoined to it by *Symphysis*, makes two superficial and side cavities disjoined by an indifferent rising; wherefore this bone is connext to the bone of the thigh by *Ginglymos*. For in the cavities thereof it receives the lower and hinder protuberances of the Appendix of the thigh bone, but the middle eminencie thereof, is received by it between the two protuberances thereof.

This joint is strengthened, not only by the force of the tendons, or muscles ending there; but also of three strong ligaments, of which one proceeds from all the externall, another from all the internal parts of thar connexion; the third which we, out of *Hippocrates*, called *Diaphysis*, from the distance or space between thəm. The other proceffe of the leg bone, which we called the lesse, seated in the lower part thereof, makes as it were a double cavity, whereby it receives the *Astragalus* or pastern bone; but on the inside it makes the ankle, as the *Perone* makes it without: between these ankles the *Astragalus* is received on the sides, and turned as the nut in a Crosse-bow, as often as there is need to bend or extend the Foot. Besides, this same leg-bone, being triangular, hath three eminencies made in the shape of an Asses back; the sharper descends along the fore part, called by the Greeks *Antionemion*; the second resides on the inner part, and the third on the outer; all these must be diligently observed, and chiefly, that on the forepart; because it is as a guide and rule to a Chirurgion in the well setting of a broken leg. The *Perone*, or shin bone, is seated, as it were, on the outside, and as behind the leg-bone; it hath also two appendices hollow on the inside, but gibbous on the out. This bone by the upper of these is fastned and inserted under the inner, and in some sort the hinder appendix of the leg bone, so that it is in no sort articulated with the thigh, but serves only in stead of a leaning stock. But by the lower, this same bone is not only received in the lowest part of the leg, or ankle, or pastern bone, but

What *Diaphysis* is.

The *Perone* *facile*, or shin bone.

also receives part thereof, which is joined on the same side with the heel, especially then when we bend our foot outwards.

This bone is fastned to the forementioned bones by *Synarthrosis*, but bound by strong ligaments proceeding from the same bones, and mutually sent from one to another, or if you had rather, from the upper into the lower, as we said in the arm. But this same *fibula* or shin bone is also triangular, having three lines, of which one stands outwards, another on the foreside, and the third behind.

CHAP. XXXVII.

Of the Muscles of the Legs.

Their number.

ALL the motions of the leg, are performed by eleven muscles, of which there be six on the foreside, and five on the hind. But of these, some move the leg only, as those which take their originall from the bone of the thigh; others truly move the leg, but with the thigh, as those which arise above the thigh, that is, from the hanch, huckle, and share bones.

The Longus.

The first of these on the foreside called the Long, but commonly the *Sutorius* (or Tailor muscle, by reason of its action) it arises from the lower and fore extremity of the spine or appendix of the hanch bone, and descending obliquely above the other muscles, is inserted by a large and membranous tendon, in the fore and inner part of the leg under the knee; the action thereof is to crosse the legs, but being first bended by the muscles presently to be treated of, it helps also the three headed muscle in the performance of the forementioned action.

The Membranosus.

The second of these four muscles is termed the *membranosus*, or membranous, because it is wholly such, unlesse at the originall where it descends fleshy from the root and basis of the above mentioned spine of the hanch bone, and that obliquely with its membranous and broad tendon (mixed with the common coat of the muscles) into the outward part of the leg, which it moves outwards, as also the thigh with the four twin muscles; for as we have in another place observed, of two oblique motions concurring in one, is made a right motion; and besides, almost all the motions of the body, are thus performed; the muscles which perform such motions are placed and opposed in an oblique site, as may be perceived by the motions and site of the muscles of the hand taken in generall.

The Rectus.

The third, called the *Rectus*, or right (because it descends above the *Crureus*, alongst the right fore line of the thigh, between the two vast muscles) comes forth between the extremity of the appendix of the hanch bone and cavity thereof, with a very strong ligament, and then is inserted into the forepart of the leg, passing over the midst of the whirlbone of the knee; it extends the leg, with the three following, but by accident it may help the bending of the thigh.

The two Vasti.

The fourth and fifth are called *Vasti*, vast or huge muscles, by reason of their largeness, the one of these is internall, the other externall: they both arise with right fibers, from their originall, but with oblique at their insertion, by reason whereof they both seem to have a compound action from a right and oblique motion; the right helping for the extension of the leg, but the oblique to draw one knee to another, or to disjoin both the knees; the internall comes by its right fibers from the root of the little *Trochanter*, but by its oblique from the inner descendent line of the thigh. The externall passes forth by its right fibers from the root of the great *Trochanter*, but by the oblique from the externall descendent line of the same bone. But all these fibers are in certain places so mixed with the *Crureus* that they cannot be separated unlesse you violate the one of them; they go into the leg (each on his side) above the whirlbone of the knee alongst the sides of the right muscle, with which it makes an unseparable tendon, as you shall presently hear. The sixth and last of these fore muscles called the *Crureus*, or thigh muscle (by reason of the strait and firm adhesion, which it hath with the thigh bone, which is by some called *Crus*) from the space between the two *Trochanters* descends under the right muscle and two vast muscles into the forepart of the thigh, even to the whirlbone of the knee. But we must note that these four last muscles make a common thick and broad tendon, with which they cover the *Patella*, or whirl bone, and all the fore dearticulation of the knee, that they cannot be separated without tearing; wherefore we must think that this tendon serves the knee for a ligament; now all these muscles performing their action together, extend the leg.

The Crureus.

The five hind muscles follow to be spoken of; of which three arise from the tuberositie of the huckle bone, going into the inner part; the fourth from the middle of the *Pubis*, called *Biceps*, that is, the two-headed muscle into the outside of the leg. Of the internall, one passing from the forementioned tuberosity, descends ligamentous even into the midst of the thigh, and then becoming fleshy, is inserted by its tendon, after the manner we formerly mentioned.

The three Internall.

The other being slender, passing forth also from the same place, with its tendon, is inserted with the tendon of the long muscle, and ends in the inner part of the leg, which with its companion, it draws inwardly, and brings to the other, which same thing it performs in the thigh, by the help of the three-headed muscle. The

The third being the inner, or hinder, descends from the middle part of the shank-bone, with a broad and slender ligament, and is inserted with a round tendon, into the inner part of the leg after the manner of the forementioned.

The fourth called *Biceps* takes one of the two heads, of which it consists, from the last mentioned tuberositie, the other from the outer line of the thigh, but is inserted into the externall part of the leg, as we formerly said.

The fifth and last called the *Popliteus* descends obliquely fleshy from the externall condyle or knot of the thigh, into the inner and hinder part of the leg, at the joining thereof to the shin-bone; the action thereof is, to draw the leg, after a manner inwards.

The *Biceps*, or two-headed muscle.

The *Popliteus* or ham muscle.

C H A P. XXXVIII.

Of the Bones of the Foot.

The Order of Anatomy requires, that we now prosecute the muscles moving the foot; but because we should in vain deliver their insertion, the disposition and condition of the bones of the foot, not being first known, wherefore it first behoves us, to set forth their description. Therefore the bones of the foot are six and twenty in number, distinguished into three ranks; that is, the bones of the *Tarsus* or Instep, are seven; those of the *Pedium*, the afterwrist, or Back of the foot, five; and those of the toes, fourteen. Of the seven bones of the instep, there are 4 named, and 3 unnamed. The first of the named immediately following the bones of the leg, is called *Astragalus*, the pastern or ankle-bone. This hath three connexions, one, as we said before, in the upper and broader part, with the bones of the leg, of which it is received; the other in the lower and hind part, by which it receives the upper and inner proceffe of the bone of the heel; the third on the fore-side by which it is received in the cavity of the *Os Naviculare* or *Scaphoides*, that is, the boat-like bone. By the first connexion the foot is extended and bended; by the second it is moved with the heel to the sides: the two first connexions are by *Diarthrosis*, the last by *Synarthrosis*. But it is strengthened by strong and broad ligaments, descending and ascending from one bone into another; also they are strengthened by membranes, muscles and tendons, descending to the foot, above and under these joints. But this bone hath three processes, as three feet fastened to the bone of the heel; of which the first and least is under the outer ankle; the bigger (which *Galen* saith, makes a round head, fastned on a long neck) looks towards the forepart of the foot, over against the great toe, and the next toe to it; the middlemost is at the heel, behind the leg-bone.

I passe over in silence many other things; as the smoothness and asperity or roughness of the bone, which I had rather you should learn by ocular inspection, than by book. The second bone lying under this is called the *Calcaneum*, or heel-bone, being the biggest of all the bones of the foot, upon which all the body relies when we go. It hath two upper processes, the one great, the other little. The great is received in the hind and outer proceffe of the *Astragalus*; the lesser is received on the inside in the third proceffe of the same bone, which we said had a round head fastned to a long neck. Besides, it is round on the hind part, and much disjointed from the leg-bone, but on the fore and longer part, it is knit by *Synarthrosis* to the Die-bone, whose lower and inner part, it seems to receive; the superficies thereof is wholly unequal, and rising up with many swellings. On the inner side it makes as it were a channell, so to give way, as well to the vessels as tendons going to the sole of the foot and toes. Lastly, we must consider the holes by which the vessels passe into that bone to give it nourishment; by reason of which vessels the fracture of this heelbone, is very dangerous, because of the pressing and contusion of the vessels; as *Hippocrates* shews. For the ligaments of this heel, or heel-bone, they are such, as these of the *Astragalus*, to wit, tendons, membranes and ligaments properly so called, coming from one bone to another. The third bone of the foot is named *Scaphoides* or boat-like, from the resemblance it hath to a boat, for on that part which looks towards the pastern bone, it is hollow; but on that part which is next the three *Innominata*, or nameless bones (which it sustains, and of which it is received, as it in the cavity thereof receives the head of the *Astragalus*) it is gibbous like the bottome of a boat. The connexions thereof are by *Synarthrosis*, and they are strengthened by the forementioned ligaments; this same bone is arched on the upper part, but somewhat hollowed or flatted below; the inner part ends in a point, like the prow of a ship, but the outer obtuse like the stern of a ship. The fourth bone of these which have names, is called the *Cuboides*, from the resemblance of a Die; although that similitude be very obscure. On the forepart it sustains the toes, which by a certain proportion to the fingers of the hand, may be called the ring and little toes; but it is sustained on the hind part, with the back part of the heel; on the inner side it is joined with the boat-like bone, and that nameless bone which sustains the middle toe; on the outside, it produces a rising like the back of an Ass, which on the lower part is extended transversely all the length thereof; at the two sides of this eminency or rising, there are two small cavities, in form of a channel.

Fig. 10, and 11. sheweth the forward and backward side of the boat-bone.

Fig. 12, 13. shew the fore and back part of the wrist made of four bones.

ABCD 3,5,6. The protuberation of the Talus joined to the appendix of the leg-bone, and of this protuberation four sides.

EE 3. A sinus insculped in the protuberation of the Talus.

FF 3, two bunching parts of the Talus.

G 3, the inner side of the protuberation of the Talus crufted over with a gristle, joined to the inner ankle.

H 6, the outward sinus of the potuberation of the Talus covered over with a gristle, and receiving the inner ankle.

I 5. A rough sinus of the Talus, receiving a gristly ligament from the inner ankle.

K 6, a sinus of the Talus receiving a gristly ligament from the outward ankle.

LM 5, 6, two sinus in the hinder part of the Talus.

N 3, 4, 5, 6. the neck of the Talus or pastern bone.

O 3, 4, 5, 6. the head of the Talus going under the sinus of the boat-bone.

P 7, 8, 9. the head of the heel crufted over with a gristle, and going under the sinus of the Talus or the pastern bone.

Q 4. a large sinus of the Talus receiving the head of the heel. R 7, 8, 9. a sinus of the heel wherto the lower part of the head of the Talus is joined. S 4. the lower power of the head of the Talus going into the sinus of the heel. TT 4. a sharp sinus of the heel receiving a gristly ligament from the pastern bone. X Y Z 2. the place of the heel. Y Z 2. Y 8. Z 9. a proceffe of the heel made for the production of muscles. a b 7, 8, 9. from a to b the distance of the upper part of the heel. c 8, 9. the hinder part of the heel. d 2, 8. the inner side of the heel. e 8. the place where the tendons that run to the bottom of the foot are reflected. f 7, 8. the utter side of the heel. g 1, 7, 9. here the tendons of the 7 and 8 muscles of the foot are stretched out. h 7. the forepart of the heel which is joined to the pastern bone. i 7. that part of the heel which is joined to the Cube bone. k 11. the sinus of the boat bone receiving the head of the Talus. l m n 10. three surfaces of the boat bone lightly prominent, which are articulated to the bones of the wrist. o p 11. the upper part of the boat bone regarding the top of the foot. q r 10. and q 11. his lower part. q 10, 11. A sinus through which the sixt muscle of the foot is led. s t u 13. the plain surfaces of the three inner bones of the wrist whereby they are articulated to the boat bone. x 13. a shallow sinus of the Cube bone whereby it is articulated to the heel. a b 12. the place of the Cube bone to which that bone of the Afterwrist is joined which supporteth the last toe save one. y 12, 13. the place of the Cube bone where the third bone of the wrist is articulated. d 12, 13. that part of the Cube bone which respects in the outside of the foot. e 12, 13. the surface of the Cube bone in the upper part of the foot. z 2, 13. that part of the Cube bone which regardeth the earth. 2, a sinus of the Cube

Cubebone at which the tendon of the seventh muscle of the foot is reflected. B 13. a proceſſe of the third bone of the wrift whereinto the liſt muscle of the foot is inserted. 12. the place of the inner bone of the wrift to which that bone of the Afterwrift which ſuſtaineth the great toe is coupled. 12. the place of the ſecond bone of the wrift whereto the bone of the Afterwrift that ſupporteth the fore Toe is articulated. 12. the place of the third bone of the wrift whereto that bone of the Afterwrift which ſupporteth the middle Toe is articulated. 1, 2. a ſmall bone whereby that bone of the Afterwrift which ſuſtaineth the little toe is joined unto the Cubebone. 1, 2 the diſtances betwixt the bones of the Afterwrift. 1, 2. the heads of the bones of the Afterwrift, which enter into the boſomes of the toes. 2, a proceſſe of the bone of the afterwrift wherein the tendon of the ſeventh muscle of the foot is implanted. 2, a proceſſe of the bone of the Afterwrift, which ſuſtaineth the little toe, which proceſſe receiveth the tendon of the eight muscle of the foot: 1, 2. the three bones of the foretoe. 2, two ſeed bones placed under that bone of the afterwrift which ſuſtaineth the great toe. * 2 under X. a ſeed bone ſet to the ſecond joint of the great Toe. 1, 2. the *Talus* or paſtern. 1, 2. the Heel. 1, 2, the Boat-bone: 1, 2. the bones of the toes. 1, 2. two bones of the great toe, I, II, III, IV, V, 1. the five bones of the afterwrift.

The firſt and the greater of the *Oſſa innominata*, or nameles bones, ſuſtains the great toe; the leſſer and ſecond, the next toe thereto; the third and middle in bigneſſe, the middle toe. Theſe three bones are arched on their upper part, but ſomewhat hollowed below. They are knit to the three forementioned bones by *Synarthroſis*, of which they are received, but on the hind part with the boat-like bone which they receive. Now we muſt come to the bones of the ſecond rank, that is, of the *Pedium*, or back of the foot; theſe are five in number, bearing up the five bones of the toes. They are ſomewhat gibbous on the upper part, but hollow below; each of them hath two proceſſes at the end thereof, by the lower and firſt of which they receive the three nameleſs and Die-bone, but by the upper made into a round head, they are received of the firſt bones of the toes. Their connexions, whether with the toes, or bones of the inſtep, are by *Synarthroſis*. The ligaments as well proper as common are ſuch, as we ſaid of the former. The bones of the third order now remain to be ſpoken of which we ſaid, make the toes, and they are fourteen, two of the great toe, but three of each of the other toes. The firſt is ſomewhat longiſh, but the reſt are very ſhort, except that of the great toe, all of them on the upper ſide are round and convex, but on the lower ſomewhat hollow, and plain long-wiſe, that the tendons which bend them, may paſſe more ſtraightly and ſafely without inclining to either ſide, even to their furtheſt joints; although ſuch paſſages are much helped by the membranous & common ligament, which riſing from the ſides of theſe bones, involves theſe tendons, as we mentioned in the fingers. To conclude, each of theſe bones, the laſt excepted, have a double connexion by *Diarthroſis*, they are all unequall in their bigneſſe, that is, thick at their beginning (where they receive the heads of the precedent bones, upon which they move as a dore upon the hinges) and ſo they grow ſmaller towards the ends, but by their ends, they are received of the following bones: at their ends they riſe into two eminencies on their ſides, diſtinguiſhed by a cavity between them, through which occaſion they are far thicker at their ends, than in their middle. The Ligaments by which their connexions are faſtned, are ſuch as the former. The *Oſſa ſeſamoidea* or ſeed bones of the feet are like in number and ſite to theſe of the hands. But this is to be noted, that thoſe ſeed-bones which are in the firſt articulation are ſomewhat bigger than the reſt, and they are round and longiſh on the outſide, but ſmooth and hollow on the inſide, ſeated between two cavities, encompassed by three riſings, of which two are on the ſides, and the third in the miſt of the extremity of the firſt bone of the *Pedium*, which chiefly bears up the great toe. To conclude, before we come to ſpeak of the muſcles, we muſt obſerve that the foot was made for two commodities. The firſt is to ſtay and bear the whole body, when we ſtand, for which cauſe nature ſet not the great toe contrary to the other, as it placed the thumb on the hand. The other is for apprehenſion, or taking hold of, wherefore nature framed and made the foot, and theſe moveable and jointed in the toes, as in the fingers of the hand. Beſides alſo for that we muſt goe upon our feet, Nature hath made them in ſome places hollow on the lower ſide, and in other ſom plain in a triangular figure, that ſo our feet may carry us over every ſoil, plain, mountainous, equal and unequal, through all parts of the world.

The *Oſſa innominata* or nameleſs bones.

The bones of the foot or *Pedium*.

The bones of the toes.

The ſeed bones of the foot.

The twofold uſe of the feet.

CHAP. XXXIX.

Of the Muſcles moving the foot.

The muſcles of the Leg moving the foot are abſolutely nine, three in the forepart and ſix in the hind. Two of the three fore muſcles bend the foot, when they jointly perform their action, but when ſeverally, each draws it to his ſide; the third chiefly extends the Toes, for other whiles it ſeems by its ſlenderer and longer tendon (which exceeds not that bone of the *Pedium* which ſuſtains the little toe) to help alſo to bend the foot.

Their number.

Musculus Peroneus.

The first is called *Peroneus*, because it descends alongst the bone *Perone*; the other the *Tibialis anticus*; for that it descends along the *Os Tibiæ*, or bone of the leg. The third from its action is called the *Digitumtensor*, or Toe-stretcher. For their originall the *Peroneus* which seems to have two heads, descends from the upper appendix of the *Perone* or shin-bone by its first head, but by the other from the middle of the same bone from the fore side into the hind, as the superficies shews which passes between the fore and outward line of the said bone; but after it arrives at the lower and hinder appendix of the same bone, behind the outer ankle it produces two tendons, which by the guidance of the Ligaments as well proper, as common, goes, the thicker under the sole of the foot, ending in the *Die*-bone and that bone of the *Pedum* which sustains the great toe; the lesser goes on the outside to the *Die*-bone, and the last and least bone of the *Pedum* which bears up the little toe, sometimes a slender portion thereof is produced even to the side of the little Toe, extending it and drawing it from the rest. The *Tibialis anticus* or fore leg muscle proceeding from the upper and outer appendix of the Leg-bone descends above the surface of the same bone, which is between the fore and outer line to which it adheres, as also to that surface even to the midst, from which place it produces one tendon, which descending on the fore and lowest part, ends on the outside into two of the nameless bones, that is, into the first which is the thicker, and into the middlemost, but besides by a slender portion thereof it is extended into the first and greater bone of the *Pedum*, so to extend the great toe, drawing it inwards to the other foot. And this muscle with the precedent bends the foot, if they both perform their parts at once; but if severally, each draws the foot towards his side. The third which is the *Digitumtensor*, or Toe-stretcher, is twofold; the one takes its originall from the top of the leg, and running alongst the shin-bone, and passing under the ring, carries it self into the foot, in which it ends by five tendons going to all the joints of the Toes, and by a sixth at that bone of the *Pedum* which sustains the little toe, whereby (as we formerly said) it helps the bending of the foot. The other descends into the midst of the shin-bone, and somewhat fastned thereto, by one tendon passing under the ring it goes to the great Toe. But you must note that all these Tendons have nervous, ligamentous and fleshy fibers so separated from each other, that they can equally alone perform their function, as if they were more distinct muscles. And we must think the same of the rest which have distinct tendons presently from their fleshy part.

Tibialis anticus.

The Toe-stretcher is twofold.

The 6 hind muscles.

The six hind muscles follow, of which the two first are called the *Gemelli* or twins by reason of the similitude of their thicknesse, originall, insertion and action. The third is called the *Plantaris*, because it is spent upon the sole of the foot, as the *Palmaris* upon the palm of the hand. The fourth is termed the *Soleus* or sole muscle by reason of the resemblance it hath to the fish of that name. The fifth the *Tibialis posticus* or hind leg muscle which descends alongst the back part of the leg-bone. The sixth and last the *Digitumflexor* or Toe-bender, equivalent to the deep muscle of the hand; some make but one muscle of this and the *Tibialis posticus*, which produces three tendons; others had rather make three, as thus, that one should be the *Tibialis*, the other the bender of four Toes, the third the bender of the great Toe.

The two *Gemelli* or twin muscles.

Now for the two *Gemelli* or twins, the one is internall, the other externall; the internall passes forth from the root of the inner Condyle of the thigh; but the externall from the external Condyle; and from this their original presently becoming fleshy, especially on the outside, they meet together a little after in their fleshy parts, and with the *soleus* they make the thick and great tendon at the midst of the leg, which from thence is inserted into the back part of the heel; in this very tendon breed painfull kibes. The action thereof is, to help our going by putting forth the foot, whilst it draws the heel towards its originall.

In what place the kibes breed
The *Plantaris*.

The *Plantaris* the least and slenderest of them all, passes forth fleshy from the outward head of the leg-bone, and from thence the space of some four fingers breadth it ends in a strong and slender tendon, which it sends between the twin and sole muscles to the sole of the foot, there to produce a membrane which covers the sole of the foot, and a muscle equivalent to the upper bender of the Hand.

The *Soleus*.

The *Soleus*, or sole muscle, the thickest of them all, and seated under the twin muscles, descends from the commissure of the leg and shin-bones, and about the midst of the leg, after it hath mixed his tendon with that of the twin muscles, it runs into the foresaid place that it may extend the foot for the foresaid use.

The *Tibialis posticus*.

The *Tibialis posticus* descends from the hinder appendix of the leg and shin-bones, and adhering to them almost as far as they goe, by a strong tendon, being as it were bony at the end thereof, it is inserted into the Boat-like bone, and the two first nameless bones, so to help the oblique extension of the foot.

The *Digitumflexor* twofold.

The last being the *Digitumflexor* or Toe-bender is twofold, for one arises from the leg-bone, in that place where the *Popliteus* ends, and inserted into that same bone it goes even to the backside of the inner ankle & from thence into the joints of four of the toes. The other draws his original from almost the middle of the shin-bone, and somewhat inserted into it, it goes by the heel and pastern bone to the great toe, mixed with the precedent; their action is to bend the first joint of the Toes, rather by the force of the common ligament, than by the small portion of the tendon which ends there. But it is their action to bend the last dear tication of the Toes by their proper insertion.

CHAP. XL.

Of the muscles moving the Toes of the feet.

NOW follow the muscles moving the Toes; these are eight in number, one on the upper, and seven on the lower side. The first proceeds from the Pastern, heel and Die bones below the external ankle, or the ligament of these bones with the leg-bone, and obliquely stretched to the top of the foot is parted into five small tendons to the sides of the five toes, so to draw them outwards towards its original, whereupon it is called the *Abductor* of the Toes, and also *Pediosus*, because it is stretched over the *Pedium* or back of the foot.

The first of the seven of the lower side called the *flexor superior* or upper bender, arises from the heel and stretched along the foot under the strong membrane, (which from the heel is straitly fastned to the extremity of the bones of the *Pedium* to strengthen the parts contained under it) is inserted by four tendons, at the second joints of the four toes which it bends. Here you must note, that near the insertion thereof, this muscle divides it self, like that muscle of the hand which is called *sublimis*, that so it may give way to the deep, which (as we said) descends along the fingers, to which a certain common membranous ligament adjoins it self, which involves and fastens it to the bone all along the lower part of the fingers, even to the last dearticulation.

The second equivalent to that muscle of the hand which is called *Thenar*, seated on the inner side of the foot, arises from the inner and hollow part of the heel and pastern bones, and ends in the side, and inner part of the great toe, which it draws from the rest, inwards. This may be divided into two or three muscles, as the *Thenar* of the hand, to draw the great toe to the rest, as much as need requires, just as we said of the Hand. The third answerable to that of the hand which is named the *Hypothenar*, passes from the outer part of the heel, and ascending by the sides of the foot it is in like manner inserted into the side of the little Toe, so to draw it from the rest; to which same action a certain flesh contained under the sole of the feet may serve, which is stretched even to these Toes, that also it may serve to hollow the foot. The four *Lumbrici* or wormy muscles follow next, which from the membrane of the deep Toe-bender are inserted into the inner and side part of the four toes, so to draw them inwards, by a motion contrary to that which is performed by the *Pediosus*. The *Interosses* or bone-bound muscles of the *Pedium* or back of the foot, remain to be spoken of: These are eight in number, four above, and as many below, different in their original, insertion and action; for the upper, because they draw the foot outwards with the *pediosus*, arise from the fore and inner part of that bone of the *Pedium*, which bears up the little Toe (and so also the rest each in its order) and are inserted into the outward and fore part of the following bone. The lower on the contrary pass from the fore and outer part of that bone of the *Pedium*, which bears up the Great Toe (and so each of the rest in its order,) but are inserted into the inner and upper part of the following bone, so with the wormy muscles to draw it inwards, or to hollow the foot as the outwards, or to flat the foot, as we said of the *Interosses* of the hand.

Their number?

The *Abductor* of the toes, or *Pediosus*.
The *Flexor superior*.

The muscle equivalent to the *Thenar*.

The 4 *Lumbrici*.

The description of the upper and lower *Interosses*.

CHAP. XLI.

An Epitome or brief recitall of the bones in a mans body.

THE whole head which hath the least consists of 60 bones; but that which hath most of 63. that is, 14 of the *Cranium* or skull, 14 or 17 of the face, and 32 teeth; Of the bones of the scull there be 8 containing, and 6 contained; the containing are, the *Os frontis*, or Forehead bone, the *Nowle*-bone, the two bones of the *Sinciput*, the two stony bones, the *Wedgbone*, and the *Sive*-like or spongy bone. But the contained are six shut up in the cavity of the Ears, the *Anvil*, *Hammer* and *Sitrop*.

For the bones of the face, there are six within or about the orb of the Eye, that is, on each side three; two bones of the Nose, two lesser Jaw bones, and two bigger, which are always in beasts seen distinguished by a manifest difference, but it is so rare in men, that I have not found it as yet; therefore these only are distinguished by manifest difference, two which contain all the upper teeth, the two inner of the palate, the two of the lower Jaw in children; And last of all the *Os Cristæ*, whence the middle gristle or partition of the Nose arise.

The two and thirty teeth are equally distributed in the upper and lower Jaws; and of these there be eight shearers, four fangs, or Dog teeth, and twenty Grinders.

The bones of the Scull 14.

The bones of the face 15.

The teeth 32.

And

The bone
Hyoides,

And there is another bone at the root of the tongue called *Os Hyoides*, alwaies composed of three bones, sometimes of four.

The bones of
the spine 34.
2 Collar-
bones.

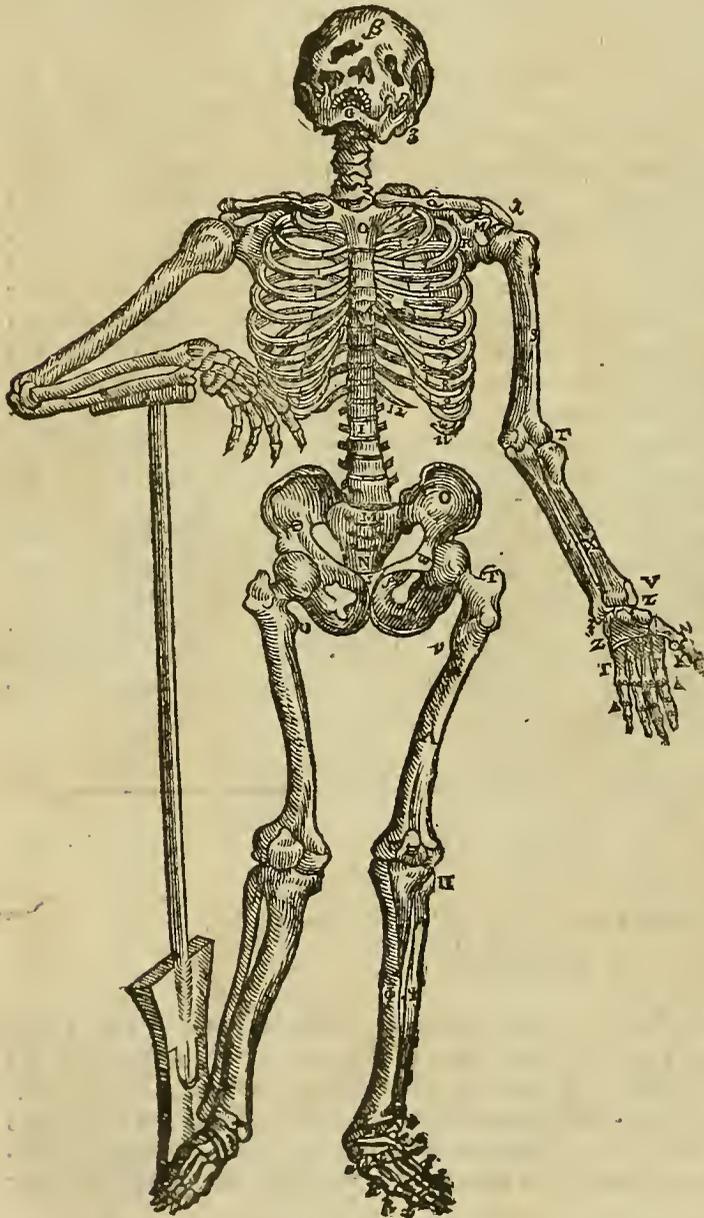

Now follow the bones of the Spine, or Back-bone, which are just four and thirty, that is, seven of the neck, twelve of the chest, five of the loins, six of the holy-bone; and four of the rump. Besides there are two bones of the throat, or Collar bones.

The ribs 24.
The bones of
the Sternon 3.
The bones of
the whole
arm 62.

The ribs are twenty four, that is, fourteen true and ten bastard ribs. The bones of the Sternon or Breast-bone most frequently three, otherwhiles seven, as sometimes in young bodies.

Hence coming to the Arms there are reckoned 62, beginning with the shoulder-blade; as there are two shoulder-blades, two Arm bones; four bones of the cubit; that is, two Ell bones and two Wands; sixteen of the Wrist, eight of the Afterwrist, and thirty of the fingers; into this number also come the *Sesamoidea* or seed bones, of which some are internall, and these alwaies twelve at the least, although sometimes there may be more found, a great part of which rather merit the name of gristles, than bones; there are others externall if we believe *Sylvius*.

The first sheweth the forepart of the Skeleton of a man, &c.

The Declaration of these three figures put into one.

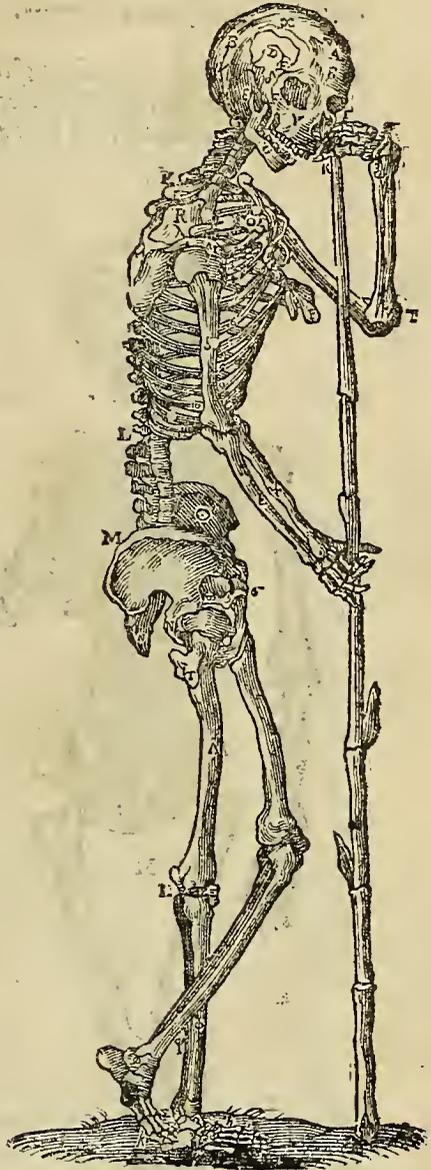

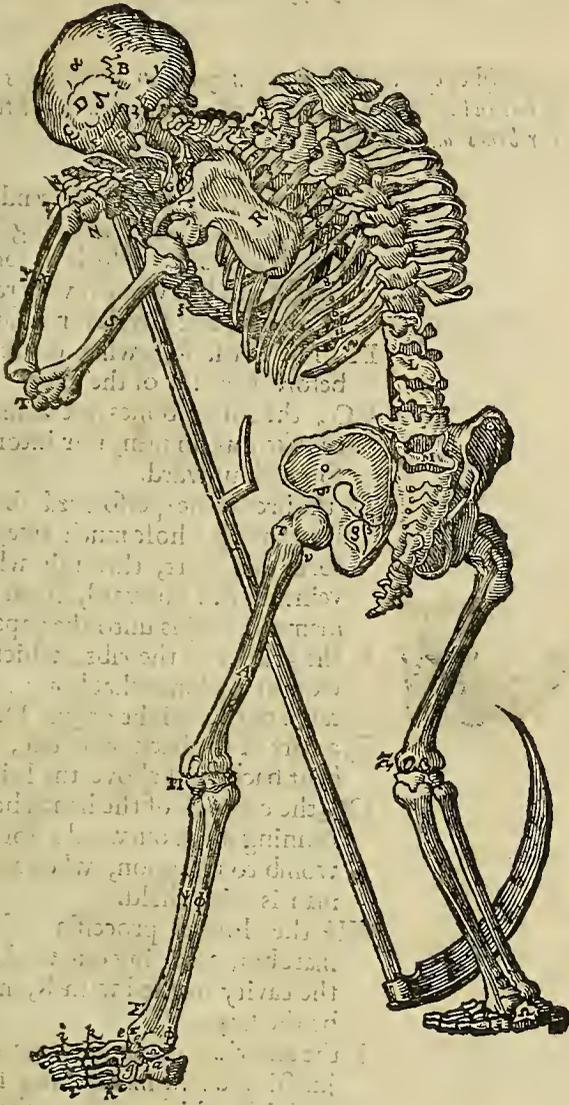

- A 3. The Coronall Suture called in Greek *σφραγιά*.
- B 2 3. The suture like the letter λ, called *λαμβδαιδής*.
- C 2. The sagittall suture called *ἰβηλιαζα*.
- D 2 3. The scale-like Conjunction called *λεπιδαιδής*.
- α 2 3. *Os verticis*, or *Syncipitis*, the bone of the Synciput, called *Os βρέγμαθ*.
- ι 3. The forehead bone, that is, *μετώπη*.
- γ 2 3. The bone of the nowl or *ivis*.
- δ 2 3. The bones of the temples or *υποταρσ*.
- ε 3. An appendix in the temple bone like a Bodkin, *σπλαειδής*.
- ζ 1 2 3. A proceffe in the temple bone like the teat of a dug, called therefore *Mamillaris* and *μασσοειδής*.
- E 2 3. The wedge bone, *σφηνοειδής*.
- η 3. The stony part of the scul.
- θ 3. A proceffe of the wedg bone much like the wing of a Bat, and therefore called *ωτερυχιδής*.

The bones of
the whole leg
66.

Now remain the bones of the leg, which (if we reckon the *Ossa Ilium* on each side three, as in young bodies, it is fit they should) they are sixty six, besides the seed-bones, that is to say, two Haunch bones, two share bones, two Huckle bones, two thigh bones, two Whirlbones of the knees, four of the leg, that is, two leg bones, and two shin bones. Fourteen of the Instep, as two heel, two pastern, two boat-like, two Die, and six namelesse bones. Ten of the *Pedium* or back of the foot, that is, five in each foot; and twenty eight of the Toes: and as many seed bones in the feet, as the hands enjoy. But I have thought good to add these figures for the better understanding of what hath been spoken hereof.

The

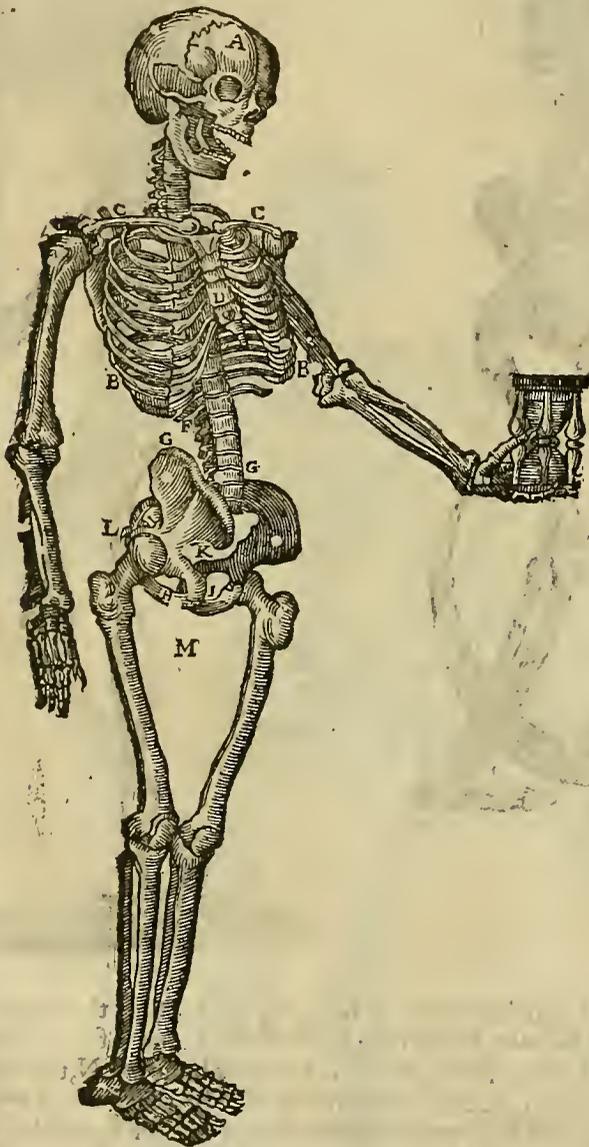

The 2 and 3 Figure sheweth the back side of the Sceleton,
and the laterall part of the Sceleton.

F 1, 2, 3. the yoaik bone ζυγία. G 1, 3. the lower jaw. I, K, L, M, N. 1, 2, 3. the back of the spine, ραχίς. From I to K, the neck, τράχηλος. From K to L, the Rack bones of the Chest. From L to M, the rack bones of the Loins. From M to N, the holy bone ἱερόν. N, the rump bone, ῥόκκος. O. 1, 3. the breast bone στήθιον. P 1, 3. the sword-like gristle of the breast, ξιφοειδής. Char. 1, 3. as far as to 12. in all three Tables, shew the twelve ribs of the Chest, πλεῦρα. Q I. the clavicles or collar bones, κλείδες. R, 1, 2, 3. the shoulder-blade, ὀμωπλάτης. λ, 1, 2, 3. The upper proceffe of the shoulder blade, or the top of the shoulder, called ἀκρομήμιον. μ, 1, 3. the lower proceffe of the shoulder blade, called ἀγχιωσθειδής. S 1, 2. the bone of the arm, called Humerus and ἄνω ὄστρον. T V 1, 2, 3. the cubit πύξος. X 1, 2, 3. the wand or the upper bone of the Cubit, called κερμαίς. Y 1, 2, 3. the ell or lower bone of the Cubit, called πύξος. 1 3. the proceffe of the cubit, ἡλικόμοιον. ξ 1 3. the proceffe like a bodkin or probe, called στυλοειδής. ZZ. 1, 2, 3. the wrist κερμαίον. ΓΓ 1, 3. the Afterwrist μετακέρμαιον. Δ Δ Δ. I. the fingers δάκτυλοι. Θ 1, 2, 3. the bones joined to the sides of the holy bone, on each side distinguished as it were into three parts. ο 1, 2, 3. the first part called the Hanch bone Os Ilium, λαγόνον. π 1, 2, 3. the second part the bone of the Coxendix ἰσχίον. ρ 1, 2, 3. the third part the share bone, Os pubis, ἕβανος. σ 1, 2, 3. a gristle going between the conjunction of the share bones. Α 1, 2, 3. the thigh, μηρῶν. τ 1, 2, 3. the greater outward proceffe of the thigh called Rotator, περιστρεφτικὸν μέγας. υ 1, 2, 3. his lesser and inner proceffe. ζ 1, 2, 3. the whirlbone of the knee, Patella Rotutula, ἐπίμυλος. Π Ξ 1, 2, 3. the leg, κνήμη. Φ 1, 2, 3. the inner and greater bone of the leg, ὀστέον ἐντὸς. Ψ, 1, 2, 3. the utter and smaller bone of the leg, called the Brace bone, Fibula, ὑπερῶν. φ 1, 2, 3. the proceffe of the leg or the inner ankle called Malleolus internus. X, 1, 2. the proceffe of the brace of the outward ankle, both of them are called in Greek σφυλῶν. Ω 1, 2, 3. the bone called the cockall, Talus,

Talus, *balista*, *Os a'ε'ε'αλθ' .a, 2,* the Heel *Calx*, *π'ε'ρνα . b 1, 3.* the bone called *Os Naviculare*, *σκαριδ'ς .cc, 1, 2, 3.* the wrist of the foot called *Tarsus*, consisting of four bones, *ταρσ' . d, e, f, 1, 2, 3.* three inner bones of the wrist of the foot, called by some *σκαριδ'ς . g 1, 2, 3.* the utter bone of the wrist of the foot like a Die, *ωβουιδ'ς . hh 1, 2, 3.* the Afterwrist of the foot called *Pedum*, by some *μετάταρσος . ii, 1, 2, 3.* the toes of the foot. *κ 1, 2, 3.* the seed bones of the foot, called *officula sesamina σπομαειδ'ς*.

This figure sheweth the Sceleton of the bones and gristles of a woman, that it may appear all her bones are in proportion lesser than the bones of a man. But in this figure only those parts are marked with letters wherin a woman differeth from a man in her bones and gristles.

- A, The sagittall future descending into the nose, and dividing the fore-head bone, which is sometimes found in women, very rarely in men, but alwaies in infants.
- BB, The Chest somewhat depressed before, because of the Paps.
- CC, the collar bones not so much crooked as in men, nor intorted so much upward.
- D, the brest bone perforated sometimes with a hole much like the form of a heart, through which veins do run outward, from the mammary veins unto the paps.
- E, the gristle of the ribs, which in women are somewhat bony, because of the weight of the Dugs.
- F, a part of the back reflected, or bent backward above the loins.
- GG, the compass of the hanch bones running more outward, for the womb to rest upon, when a woman is with child.
- HH, the lower proceses of the share bones, bearing outward, that the cavity marked with K, might be the larger.
- I, the anterior commissure or conjunction of the share-bones filled up with a thick gristle, that in the birth they might better yeeld somewhat for natures necessity.
- K, a great and large cavity circumscribed by the bones of the coxendix and the Holy-bone.
- L, The rump or cœcyx, curved backward to give way in the time of the birth.
- M, the thigh bones by reason of the

largeness of the foresaid cavity, have a greater distance betwixt them above, whence also it is that womens thighs are thicker than mens.

CHAP. XLII.

An Epitome of the names and kinds of composure of the bones.

Because it is as necessary for a Chirurgion to know the manner of setting and repairing broken bones, as to put them in their places when they are dislocated, or out of joynt; but seeing neither of them can be understood when the naturall connexion of the bones is not knowne, I have thought it a worke worth my labour, briefly to set down, by what and how many means the bones are mutually knit and fastned together. The universall composure and structure of all the bones in a mans body is called by the Greeks *Sceletos*. But all these bones are composed after two sorts, that is, by *Arthron*, an Articulation or joint, and by *Symphysis* a naturall uniting or joining together.

What the *Sceletos* is.

The

There are many other kinds both of these sorts. For there are two kinds of Articulation, that is, *Diarthrosis*, or Dearticulation, and *Synarthrosis*, or Coarticulation; which differ as thus, Dearticulation is a composition of the bones with a manifest and visible motion; Coarticulation hath a motion of the bones, yet not so manifest, but more obscure. But these two do again admit a subdivision into other kinds. For *Diarthrosis* contains under it *Enarthrosis*, *Arthrodia*, and *Ginglymos*. Now *Enarthrosis* or Inarticulation is a kind of Dearticulation, in which a deep Cavity receives a thick and long head, such a composition hath the Thigh-bone with the Huckle-bone.

Arthrodia is when a lightly engraven cavity admits a small and short head; such a connexion is that of the arm-bone with the shoulder-blade; of the first *vertebra* with the second. The Greeks have distinguished by proper names these two kinds of Cavities and heads; For they call the thick and long head *Cephalé*, that is, a Head absolutely; but the lesser they term *Corone*, or *Coronon* which the Latines call *Capitulum*, a Little-head. But they call a deep Cavity *Cotyle*, and a superficial one *Glene*. The third sort called *Ginglymos*, is when the bones mutually receive and are received one of another; as when there is a cavity in one bone, which receives the head of the opposite bone, and also the same bone hath a head which may be received in the Cavity of the opposite bone; such a composition is in the Cubic knee, that is in the connexion of the Thigh-bone.

And thus much of Dearticulation and the three kinds thereof. *Synarthrosis* or Coarticulation, another kind of juncture, hath also three kinds thereof (*Gal. lib. de Ossibus*) to wit, *Sutura*, *Gomphosis* and *Harmonia*.

Suture is a composition of the bones after the manner of sowing things together, example whereof appears in the bones of the Skull. *Gomphosis* is when one bone is fastened in another as a pin is fastened in a hole, after which manner the teeth are fastened in their sockets in both the Jaws. *Harmony* is when the bones are composed by the interposition of a simple line, after which manner many bones of the nose and face are joined together.

Hitherto we have spoken of the first construction of the bones by articulation and the kinds thereof; now it follows we treat of *Symphysis*.

Symphysis, or growing together, as we formerly said, is nothing else, than naturall union of the bones; such union is made two manner of wayes, that is, either by interposition of no other thing; after which sort in success of time the bones of the lower Jaw grow together, which formerly in children were manifestly distinguished; or by the mediation of some *Medium*; but that happens three manner of wayes, by interposition of three severall *Media*, as first of a Gristle, which kind of union the Greeks call *Synchondrosis*, after which manner the Share-bones grow together and also some *Appendices* in young bodies; secondly, of a Ligament, and it is named by the Grecians *Syneurosis*, the Name of a Nerve being taken in the largest sense, for sometimes it is used for a tendon, otherwhiles for a Ligament, otherwhiles for a Nerve properly so called and which is the author of sense and motion. But this *Symphysis* or union hath place by *Syneurosis*, or interposition of a Nerve, in certain bones of the *Sternon* and Haunch.

Thirdly, the bones grow into one by interposition of flesh, called in Greek *Synsarcofis*; thus the flesh of the Gums fasten the teeth and makes them immoveable. But if some be less pleased with this division, by reason of the obscurities, in which it seems to be involved, this following expression comes into my mind, which I was first admonished of by *German Cortin* Doctor of Physick, which if you well observe it, is both blameless and more easie for your understanding.

An Epitome or brief recitall of all the Muscles of mans body.

As I have formerly reckoned up the bones, so here, I have decreed to recite the muscles of mans body. Wherefore in the face we first meet with the broad or skin muscle arising from the fleshy pannicle, and covering the whole neck and almost all the face. Then follow 4, pertaining to the upper eye-lids. In the Orbs of the eyes lye 14, that is 7, in each Orb, of which 4 are called right, two oblique, and one pyramidall. Then succeed 4 of the nose, two externall on each side one, and two internall, these draw it together and the other open it. After these come the ten muscles of the lower Jaw, of which two are called the *Crotaphite* or Temporall; two *Masseteres* or Grinders; two round (which seem to mee rather to pertain to the lips, than to this Jaw;) two little ones hid in the mouth, arising from the winged process of the wedg-bone; two openers of the mouth being nervous or tendinous in their midst. Then follow the 8 muscles of the lips, that is, 4 of the upper, and as many of the lower, shutting and opening the mouth. The tongue with his ten muscles is hid as it were in the den of the mouth. Wherefore the muscles of the whole face are 51. In the fore part of neck are found the muscles of the bone *Hyoides* and throttle; now 8 muscles hold the bone *Hyoides* as equally ballanced; of which there are 2 upper arising from the Chin; 2 on the sides from the proceffe *Styloides*, perforated in their midst, through which the 2 openers of the mouth in that part nervous do pass; 2 arise from the *Sternon*, and lastly 2 from the upper rib of the shoulder-blade to the *Coracoides*, which also in their midst are nervous, in which place the two *Massoidei* lye upon them.

2 Sorts of Articulation.
What *Diarthrosis* and *Synarthrosis* are.
3 Sorts of *Diarthrosis*.
What *Enarthrosis* is.

What *Arthrodia*.

What *Cephalé* is.

What *Corone* is.

What *Cotyle* is.

What *Glene* is.

What *Ginglymos*.

3 kinds of *Synarthrosis*.

What a *Suture* is.

What *Gomphosis* is.

What *Harmonia* is.

What *Symphysis* is.

Synchondrosis.

Syneurosis.
The things signified by the word Nerve.

Synsarcofis.

United mutually by *Symphysis* or union; by which they are so conjoined that there is no dissimilar, nor heterogenous body, at least which may be discerned, interposed between them. Such union appears in the two bones of the lower Jaw at the Chin, in the bones of the *Sternum*, the Hanch with the Huckle-bones, and the Share-bones between themselves; of this union there are no more kinds, for by this it cometh to pass, that the bones which were more and distinct meet together by interposition of one *Medium*, to wit, a Gristle, which now indeed is no Gristle, but is turned into a Bone.

The bones, which as pillars sustain the fabric of the whole body, are either

or Conjoined by that which they call *Arthrodia*, or Articulation, as when they so concur & are bound together, that some Heterogeneous substance may be noted berwixt them, but the bones thus composed are knit two manner of wayes, that is,

either more loosely as by *Diarthrofis*, that is a kind of Articulation not very strait, as by which it might have opportunity to perform diverse motions: of this composure or Articulation of bones there are three kinds, as

or more straitly, as by *synarthrosis*, when the bones are more straitly knit so that they can perform no motions in the body. Of this Articulation there are also 3 kinds, that is,

Enarthrosis, when the head of a bone is wholly received in the cavity of another, and hid therein, as the Thigh-bone is joyned with the Huckle-bone.

Arthrodia, when in a lightly engraven and not much depressed cavity the head of another bone is not wholly hid, but only received in part thereof; so that unless nature had otherwise provided a sufficient receptacle for the head of this bone (as by the ligaments of the neighbouring Muscles) it would otherwise have been in perpetuall danger of dislocation. Thus the Arm-bone is fastened to the shoulder-blade.

Ginglymos, when the bones mutually receive each other, such like composition hath the Cubit and Arm-bone.

Gomphysis, as when one bone so receives another as a Pin is fastened in the hole made by a piercer, thus the teeth are fastened in the Jaws.

Sutura, like a Saw, or teeth of a combe; as the bones of the skull are mutually knit together, or as scales, or tiles are laid, after which manner the stony bones are fastened to these of the *Synciput*.

Harmonia, which is by interposition of a simple line, which parts bones abutting one upon another, as the bones of the Nose.

The 18. of the *Larinx*.

The Throttle composed of three gristles hath eighteen or twenty muscles, of which six or eight are common, and twelve proper; Of the common there are two above, two below, and two at the sides of the first gristle, to which we may add these two which serve for the opening of the *Epiglottis*, which are alwayes found in great four-footed beasts for to press down the *Epiglottis*.

The proper are twely, which almost all of them come from the second gristle, so to be inserted into the first and third, of which some are before, others behind the *Thyroides*. Besides these there are the *Mastoidei* which bend the head.

The head is moved by 14 Muscles.

But in the back part of the Neck there are twelve muscles also appointed for to move the head, so that in all there are fourteen muscles serving for the motion of the head, the two fore *Mastoidei*, and the twelve hind muscles; that is to say, the two *Splenii*, two *Complexi*, four Right, and so many oblique, which are very short, so that they pass not beyond the first and second *vertebra*.

The 8. muscles of the neck.

The Neck hath eight Muscles, of which two are called the Long, lying before upon the bodies of the *Vertebrae*; the two *Scaleni*, which are at the sides; the two *Spinati*, which run alongst the Spine; the two transverse, which go to the transverse process of the Chest.

The Muscles of the chest 81

The Chest hath 81 Muscles, of which some are on the fore part, some on the hind, others on the sides; they are all combined and coupled together except the Midriffe. Now of these there are the two *Subclavii*; the two great Saw-muscles which proceed from the basis of the shoulder-blade; the four little *Rhomboides* or square muscles, that is, two above, and two below; the two *Sacrolumbi*, the two binders of the Gristles within the Chest.

Besides there are twenty and two externall and as many internal Intercofall muscles, twenty four *Intercartilaginei*, that is, twelve externall and as many internal; so that the Intercofall, and *Intercartilaginei* are 68, which with the twelve before mentioned make the number of 80 Muscles. Add to these the Midriffe being without an associate, and you shall have the number formerly mentioned; to wit, 81. But also if you will add to these the Muscles of the lower belly, I will not much gainsay it, because by accident they help inspiration and expiration.

The 8. muscles of the lower belly.

Wherefore of the eight muscles of the *Epigastrium*, there are four oblique, of which two are descendent and so many ascendent; two right, to which you may add the two Assisting or

or Pyramidall muscles which come from the Iliac-bone, if it please you to separate them from the head of the right muscles.

There are six or eight muscles of the Loins, of which two bend the loins, which are the triangular; the two *Semispinati*; two *Sacri*; two are in the midst of the back, which for that cause we may call the *Rachitæ* or chin-muscles. Now, that hereafter we may severally and distinctly set down the muscles of the extreme parts, we will come to the privities.

The 6. or 8. of the loins.

Where for the use of the testicles there are two muscles called the *Cremasteres*, or Hanging muscles. At the root of the yard, or *Perinaum*, there are four others, partly for the commodious passing of the urin and seed, and partly for erecting the yard. The *Sphincter* muscle is seated at the neck of the Bladder.

The two Cremasteres of the Testicles.

At the end of the right gut are three muscles, two *Levatores Ani*, or lifters up of the fundament, and one *Sphincter* or shutting muscle. Now let us prosecute the muscles of the extremities, or limbs. But it will be sufficient to mention only the muscles of one side, because seeing these parts of the body are double, those things which are said of the one may be applied to the other.

The three of the fundament.

Wherefore the muscles of the Arm, beginning with these of the shoulder-blade, at the least, are 42. for there are four of the shoulder-blade: of the Arm properly or particularly so called, seven or eight; and there are three, four or five proper muscles of the Cubit; that is, appointed for the performance of the motions thereof; in the inner part of the Cubit are seven, and as many in the outer; but those of the hand are reckoned thirteen at the least.

The muscles of the Arm in general 32.

The fourth of the shoulder-blade are the *Trapezius* resembling a Monks Cowl, which moves it upwards and downwards, and draws it backwards; the second is the *Levator*, or lifter-up; the third the great *Rhomboides* lying under the *Trapezius*. The fourth, the lesser saw muscle which is inserted into the *Coracoïdes*. The arm is moved forwards, backwards, upwards, downwards and circularly.

The Pectorall muscle arising from the Clavicle, Brest-bone and neighbouring ribs, draws it forwards; the *Humilis* or low muscle coming from the lower rib of the shoulder-blade draws it backwards; the *Deltoides* upwards; and the *Latissimus* downwards, and somewhat backwards. But the three seated about the shoulder-blade move it about, or circularly.

The *Epomis* or *Scapularis* upwards; the *Superscapularis*, which may seem two, backwards and downwards; the *Subscapularis* which is in the Cavities of the shoulderblade, forwards, so that by a certain vicissitude and succession of action they move it circularly. Two muscles bend the Cubit, the one named *Biceps* or two-headed, and the other *Brachialis* or the Arm muscle; but one, two or three muscles extend it; for if you have respect to the original, this muscle hath two or three heads, but one only insertion.

In the inside of the cubit are seven muscles, one *Palmaris*, two wrist benders; two *pronatores*, one square, another in some fort round; two finger benders, and one *Abductor* or Drawer aside. These fourteen internall and externall muscles of the Cubit, do not indeed move the Cubit, but only seated there move the wand and with it the hand. These are the thirteen muscles of the hand; the *Thenar* which may not only be divided into two, but into six, not only by the diverse actions it performs, but also by the branches divided by a manifest space between them; the second is called the *Hypothenar*, which lies under the little finger, as the *Thenar* doth under the thumb; the third is the *Abductor* of the thumb; then follow the four *Lumbrici* and six *Interosses*, although eight may be observed.

The whole leg hath at the least 50 muscles, for we reckon there are fourteen muscles in the thigh; there are eleven made for the use of the Leg; there are nine seated in the Leg, three before, and six behind, which serve for the use of the foot and toes; in the foot are seated sixteen. Therefore of the fourteen muscles serving the thigh two bend it, one called the *Lumbaris*, the other arising from the cavity of the Hanch bone; but the three which make the Buttocks and the *Triceps* or Three-headed muscle, (which if you please, you may divide into three) extend it. Besides these the four twin muscles, and two *Obturator*s, of which the one is internal, and the other external turn the thigh about. The leg hath eleven; that is, the Long, the membranous, the four *Postici* or hind muscles (three of which come from the Hucklebone, but the other from the commissure of the Share bone) the right, the two vast, the *Crureus* or Leg muscle, and the *Popliteus*, or ham muscle. These seated in the leg for the use of the foot and toes are three fore, and six hind muscles: two of the fore bend the foot, one of which is called the *Tibiæus anticus*, the other *Peroneus*, which you may divide into two. The third the bender of the toes, although it also partly bend the foot, to which also the bender of the thumb may be revoked. One of the hind is the Toe-bender, others extend the foot; and are in this order; two Twins, one *Plantaris*, one *Soleus*, one *Tibiæus posticus* and the great bender of the toes, to which may be revoked the bender of the thumb. Of the sixteen seated in the foot, one is above, seated on the back of the foot, which we call the *Abductor* of the Toes; another in the sole of the foot; to wit, the little bender of the Toes, which goes to the second joint of the Toes alongst the inside of the foot; the other lends his help to the great Toe, which you may call the *Abductor* of the thumb; another

The muscles of the leg in general 50.

ther is seated on the outside for the use of the little toe. To these are added the four *Lumbri*, besides the eight *Interossei*; or if you had rather, ten. And thus much may suffice for the enumeration of the muscles.

The Figure of the muscles when the skin with its veins, the fat, and all the fleshy membranes are taken away, that part of the fleshy membrane excepted, which takes upon it the nature of a muscle, as being conjoined with the muscles.

- a, the muscle of the forehead.
 b, the temporall muscle.
 c, the muscle shutting the eyelid.
 d, the muscle opening the wings of the nose.
 e, the fore part of the yolk-bone.
 f, the muscle of the upper lip tending to the nose.
 g, the beginning of the masseter or grinding muscle.
 h, the broad muscle consisting of a fleshy membrane.
 i, k, the beginning thereof which rises immediately from the collar-bone and the top of the shoulder.
 l, that part thereof which bends forwards to l.
 m, the muscle which lifts up the arm.
 n, the pectorall muscle.
 o, the membranous part of this muscle which is joined to the nervous part of the first muscle of the *Abdomen*, or belly.
 p, q, the fleshy portion thereof, from the 6 and 7 ribs, and the insertion

thereof. r the muscle drawing down the arm. s, the oblique descending muscle of the lower belly. t, t, t, the insertion of the greater saw muscle. u u. the *linea alba* or white line, at which the two oblique descendent muscles meet, covering the whole belly. x, the yard, the skin being taken away. y, the vessels of feed. z, the testicles wrapped in the fleshy membrane. a, the fore muscle bending the cubit. b, b, the hind muscle bending the cubit. c, the muscle extending the cubit. d, the two-headed muscle extending the wrist. e, the muscle producing the broad tendon on the back of the hand. f, his tendon. g, the muscle turning up the Wand. h, the upper muscle flattening the Wand. i, the second of the arm-benders, whose beginning is k, and tendon l. m, a portion of the muscle, whereof one part yeelds tendons to the wrist, the other to the thumb. n, the fleshlesse articulation of the thumb. o, a muscle inserted into the wrist, lying neer to the following muscle. p, a muscle divided into two tendons, the one whereof is inserted into the first joint of the thumb, the other into the following. q, the first muscle of the thigh, whose head is at r, and tendon at s, and insertion at x. y, the end of the second muscle of the thigh. z, the end of the third muscle of the thigh. a, the sixth muscle of the leg; his beginning at b, almost wholly membranous at c. d, the ninth muscle of the leg. e, the eighth of the leg. f, a portion of the sixth and seventh of the thigh. g, the Glandules of the groins. h, the eighth of the thigh. i, the second of the leg. j, the innermost of the ankle. k, the sixth muscle of the foot, his originall l. end m. n, the seventh of the foot. o, the tendon of the muscle lifting up the great toe. p, the muscles extending the four other toes. q, the abductor of the great toe. r, a transverse ligament. s, a tendon of the ninth muscle of the foot. t, the first muscle. u, the fourth muscle of the foot. v, the tendon of the third muscle. w, x, a muscle bending the third bone of the four lesser toes.

THE
SEVENTH BOOK
Of Tumors against Nature
in generall.

CHAP. I.

What a Tumour against Nature, vulgarly called an Impostume, is, and what be the differences thereof.

AN Impostume, commonly so called, is an affect against nature, composed and made of three kinds of diseases, Distemperature, ill Conformation, and Solution of Continuity, concurring to the hindering or hurting of the Action. An humor, or any other matter, answering in proportion to a humor, abolishing, weakning, or depraving of the office or function of that part or body in which it resides, causeth it. The differences of Impostumes are commonly drawn from five things; quantity, matter, accidents, the nature of the part, which they affect or possess; and lastly, their efficient causes. I have thought good for the better understanding of them, to describe them in this following Scheme.

What an Impostume vulgarly so called is.

The materiall causes of Impostumes, or unnatural tumors;

A Table of the differences of Tumors.

From their quantity, by reason whereof Impostumes are called	From their accidents, as	Natural	Great, which are comprehended under the generall name of Phlegmons, which happen in the fleshy parts, by Galen, Lib. de tumor. contra naturam, & lib. 2. ad Glauconem.	of a sanguine humour,	Carbuncles, Gangrenes, eating ulcers, Sphacels are caused,
			Indifferent, or of the middle sort, as Fellons.		
From the matter, of which they are caused and made, which is either	Natural	or	Small, as those which Avicen calls Bothores, i. Pusshes and Pustules, all kind of Scabs and Leprosies; and lastly, all small breakings out.	of a phlegmatick humor,	Watery and stultent Impostumes, the Kings evil, knots and all phlegmatick swellings and excrescences.
			Colour, from whence Impostumes are named white, red, pale, yellow, blew or black, and so of any other colour.	of a melancholick humor.	The exquisite or perfect Scirrhus, hardneses and all sorts of cancerous Tumors.
The differences of Impostumes are drawn principally from five things, that is,	From the condition and nature of the parts which they possess, from whence the Ophthalmia, is a Phlegmon of the eyes. Parot is a tumor near the ears. Faronychia or a whitlow at the roots of the nails; and so of the rest.	Not naturall, which hath exceeded the limits of its naturall goodnesse, from whence illegitimate tumors, therefore	Pain, hardnes, softnes, and such like, from whence they are said to be painfull, not painfull, hard, soft, and so of the rest.		
			Hot, and that either Sanguin, from whence a true Phlegmon; either Choleric, frō whence a true Erysipelas. Cold, & that either, Phlegmatick, frō whence a true Oedema; either, Melancholick, frō whence a perfect Scirrhus.		

CHAP. II.

Of the generall causes of Tumors.

After what manner tumours against nature are chiefly made.

Here are two generall causes of Impostumes, Fluxion, and Congestion. Defluxions are occasioned, either by the part sending, or receiving; the part sending discharges it self of the humors, because the expulsive faculty resident in that part is provoked to expell them, moved thereto, either by the troublesomness of their quantity or quality. The part receiving draws, and receives occasion of heat, pain, weaknesse (whether naturall, or accidentall) opennesse of the passages, and lower situation.

Three causes of heat.

The causes of heat, in what part soever it be, are commonly three, as all immoderate motion (under which frictions are also contained,) externall heat, either from fire or sun, and the use of acrid meats and medicines.

Four causes of pain.

The causes of pain are four, the first is a sodain and violent invasion of some untemperate thing, by means of the four first qualities; the second is solution of continuity, by a wound, luxation, fracture, contusion, or distention; the third, is the exquisit sense of the part, for you feel no pain in cutting a bone, or exposing it to cold or heat; the fourth is, the attention, as it were, of the animall faculty; for the mind diverted from the actual cause of pain, is lesse troubled, or sensible of it.

Two causes of weaknesse.

A part is weak, either by its nature, or by some accident; by its nature, as the Glandules and the Emunctories of the principall parts; by accident, as if some distemper, bitter pain, or great defluxion have seized upon it, and wearied it, for so the strength is weakned, and the passages dilated. And the lownesse of site yeelds opportunity for the falling down of humors.

Two causes of congestion.

The causes of congestion are two principally, as the weaknesse of the concoctive facultie, which resides in the part, (by which the assimilation into the substance of the part of the nourishment flowing to it is frustrated) and the weaknesse of the expulsive faculty; for whilst the part cannot expell superfluities, their quantity continually encreases.

And thus oftentimes cold Impostumes, have their originall from a grosse and tough humor, and so are more difficult to cure.

Lastly, all the causes of Impostumes may be reduced to three; that is, the primitive, or externall; the antecedent, or internall; and the conjunct, or containing, as we will hereafter treat more at large.

CHAP. III.

The signes of Impostumes or Tumors in generall.

The principall signs of tumors are drawn from the essence of the part.

Before we undertake the cure of Tumors, it is expedient to know their kinds and differences, which knowledg must be drawn from their proper signs, the same way, as in other diseases. But because the proper and principall signs of tumors are drawn from the essence of the part they possesse, we must first know the parts, and then consider what their essence and composition are.

We are taught both by skill in Anatomy, and the observation of the deprived function, especially when the affected part is one of those which lie hid in the body; for we know whether or no, the externall parts are affected with a tumor against nature, by comparing that with his naturall which is contrary. For comparing the sound part with the diseased, we shall easily judge whether it be swollen, or no.

But because, it is not sufficient for a Chirurgeon only to know these generall signs (which are known even to the vulgar) he must attentively observe such as are more proper and neer. And these are drawn from the difference of the matter and humors, of which the tumors consist.

For this Galen teaches, that all differences of tumors arise from the nature and condition of the matter which flows down and generates the tumor; also they are known by such accidents as happen to them, as colour, heat, hardness, softness, pain, tension, resistance.

Wherefore pain, heat, rednesse, and tension indicate a sanguine humour; coldnesse, softnesse, and no great pain, phlegm; tension, hardness, the livid colour of the part, and a pricking pain by fits, melancholy; and yellowish and pale colour, biting pain without hardness of the part, choler.

And besides, Impostumes have their periods and exacerbations following the nature and motion of the humors of which they are generated. Wherefore by the motion and fits it will be no difficult matter to know the kind of the humor; for as in the spring, so in the morning the blood is in motion; as in the summer, so in the midst of the day, choler; as in Autumn, so in the evening, melancholy; as in Winter, so in the night the exacerbation of phlegm are most predominant. For Hippocrates and Galen teach, that the year hath circuits of diseases, so that the same proportion of the excess and motion of humors, which is in the four seasons of the year, is also in the four quarters of each day. Im-

Lib. 2. ad Glanc. & 13. methed.

The proper signs of a sanguine tumor, of a phlegmatick, of a melancholick, of a cholerick. The knowledg of tumors by their motion and exacerbation.

Lib. 2. Epidem.

Impostumes which are curable have four times, their beginning, encrease, state, and declination, and we must alter our medicines, according to the variety of these times. We know the beginning by the first swelling of the part; The encrease, when the swelling, pain, and other accidents do manifestly encrease, and enlarge themselves; the state, when the foresaid symptoms increase no more, but each of them, because at their height, remain in their state immoveable, unless the very matter of the tumor degenerate; and change it self into another kind of humor; The declination, when the swelling, pain, feaver, restlessness are lessened. And from hence the Chirurgeon may presage what the end of the tumor may be; for tumors are commonly terminated four manner of wayes, if so be that the motion of the humors causing them be not intercepted, or they without some manifest cause, do flow back into the body.

The beginning
of an impostume.
The encrease.
The state.

Therefore first they are terminated by insensible transpiration, or resolution; secondly, by suppuration when the matter is digested and ripened; thirdly, by induration, when it degenerates into a Scirrhus, the thinner part of the humor being dissolved; the fourth, which is the worst of all, by a corruption and Gangrene of the part, which is, when overcome with violence, or the abundance or quality of the humor, or both, it comes to that distemper, that it loses its proper action.

It is best to terminate a tumor by resolution; and the worst by corruption; suppuration and induration are between both, although that is far better than this. The signs by which the Chirurgeons may presage that an Impostume may be terminated by resolving, are the remission or slackening of the swelling, pain, pulsation, tension, heat, and all other accidents, and the unaccustomed liveliness and itching of the part; and hot Impostumes are commonly thus terminated, because the hot humor is easily resolved, by reason of its subtilty.

The signs of a tumor to be terminated by resolution.

Signs of suppuration are the intension or encrease of pain, heat, swelling, pulsation, and the feaver; for according to *Hippocrates*, pain and the feaver are greater when the matter is suppurating, than when it is suppurated.

The signs of suppuration.

The Chirurgeon must be very attentive to know and observe when suppuration is made; for the purulent matter oft-times lies hid (as *Hippocrates* saith) by reason of the thickness of the part lying above, or over it.

The signs of an Impostume degenerating into a Scirrhus hardness, are the diminution of the tumor, and hardness remaining in the part. The causes of the hardness not going away with the swelling, are the weakness of nature, the grossness and toughness of the humor, and unskilfulness of the Chirurgeon, who by too long using resolving things hath occasioned, that the more subtil part of the humor being dissolved, the rest of the grosser nature like earthy dregs remains concrete in the part. For so Potters vessels dried in the Sun grow hard. But the unskilfull Chirurgeon may occasion a Scirrhus hardness by another means; as by condensating the skin, and incrassating the humors, by too much use of repercussives. But you may perceive an Impostume to degenerate into a Gangrene thus, if the accidents of heat, redness, pulsation and tension shal be more intense, than they are wont to be in suppuration; if the pain presently cease without any manifest cause; if the part wax livid or black; and lastly, if it stink.

The signs and causes of a tumor terminated in a Scirrhus.

The signs of a Gangrene at hand.

But we shall treat of this more at large when we come to treat of the Gangrene and *Sphacelus*. A sodain diminution of the tumor, and that without manifest cause, is a sign of the matter fallen black, and turned into the body again, which may be occasioned by the immoderate use of refrigerating things. And sometimes much flatulencie mixed with the matter, although there be no fault in those things which were applied.

Of disappearance of a tumor, and the signs thereof.

Feavers and many other malign Symptoms, as swooundings and convulsion, by translation of the matter to the noble parts, follow this flowing back of the humor into the body.

CHAP. IV.

Of the Prognostiques in Impostumes.

Tumors arising from a melancholy, phlegmatick, grosse, tough, or viscous humor, aske a longer time for their cure, than those which are of bloud or cholér. And they are more difficultly cured which are of humors not naturall, than those which are of humors yet contained in the bounds of nature.

Cold tumors require a longer cure.

For those humors which are rebellious, offend rather in quality, than in quantity, and undergoe the divers forms of things dissenting from nature, which are joined by no similitude or affinity with things naturall, as suct, poultis, hony, the dregs of oil, and wine; yea, and of solid bodies, as stone, sand, coal, straws; and sometimes of living things, as Wormes, Serpents, and the like monsters.

Tumors made of matter not naturall, are more difficultly cured.

The tumors which possesse the inner parts, and noble entrails, are more dangerous and deadly, as also those which are in the joints, or neer to them. And these tumors which seise upon great vessels, as veins, arteries, and nerves, for fear of great effusion of blood,

Hippo. Aph. 8.
sect. 6.

wasting of the spirits and convulsion. So Impostumes of a monstrous bigness are often deadly by reason of the great resolution of the spirits caused by their opening. Those which degenerate into a *Scirrhus* are of long continuance and hard to cure, as also those which are in hydropick, leprous, scabby and corrupt bodies, for they often turn into malign and ill conditioned ulcers.

CHAP. V.

Of the generall cure of Tumors against Nature.

What must be considered in undertaking the cure of tumors.

Here be three things to be observed in cure of Impostumes. The first is the essence thereof; the second, the quality of the humor causing the Impostume; the third, the temper of the part affected. The first indication drawn from the essence, that is, from the greatnesse or smalnesse of the tumor, varies the manner of curing, for the medicines must be increased or diminished according to the greatnesse of the tumor. The second, taken from the nature of the humor also changes our counsell, for a *Phlegmon* must be otherwise cured than an *Erysipelas*, and an *Oidema* than a *Scirrhus*, and a simple tumor, otherwise than a compound. And also you must cure after another manner a tumor coming of an humor not natural, than that which is of a natural humor, and otherwise that which is made by congestion, than that which is made by defluxion. The third Indication is taken from the part in which the tumor resides; by the nature of the part we understand its temperature, conformation, site, faculty, and function.

What we must understand by the nature of the part.

The temperature indicates that some medicines are convenient for the fleshy parts, as those which are more moist; others for the nervous, as more drie; for you must apply some things to the eye, and others to the throat; one sort of things to these parts which by reason of their rarity are easily subject to defluxion, another to those parts which by their density are not obnoxious to it.

But we must have good regard to the site of the part, as if it have any connexion with the great vessels, and if it be fit to powre forth the matter and humor when it is suppurated.

What we must understand by the faculty of the part.

Galen by the name of Faculty understands the use and sense of the part. This hath a manifold indication in curing, for some parts are principall, as the Brain, Heart, and Liver; for their vertue is communicated to the whole body, by the nerves, arteries, and veins.

What we must consider in performing the cure.

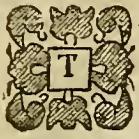

Others truly are not principall, but yet so necessary that none can live without them, as the stomach. Some are endued with a most quick sense, as the eye, the membranes, nerves, and tendons; wherefore they cannot indure acrid and biting medicines. Having called to mind these indications, the indication will be perfected by these three following intentions, as if we consider the humor flowing down, or which is ready to flow; the conjunct matter, that is, the humor impact in the part; the correction of accidents; yet so that we alwaies have care of that which is most urgent and of the cause. Therefore first repercussives must be applied for the antecedent matter, strong or weak, having regard to the tumor as it is then, only excepting six conditions of tumors; the first is, if the matter of the tumor be venenate: the second, if it be a criticall abscess: the third, if the defluxion be near the noble parts: the fourth, if the matter be grosse, tough, and viscid: the fifth, when the matter lies far in, that is, flows by the veins which lies more deep: the sixth, when it lies in the Glandules. But if the whole body be plethorick, a convenient diet, purging and Phlebotomie must be appointed, frictions and bathes must be used. Ill humors are amended by diet and purging. If the weakness of the part receiving draw on a defluxion, it must be strengthened.

What things disswade us from using repercussives.

If the part be inferior in its site, let the patient be so seated, or layed, that the part receiving, as much as may be, may be the higher. If pain be the cause of defluxion, we must asswage it by things mitigating it. If the thinnesse, or lightnesse of the humor cause defluxion, it must be inspissate by meats and medicines. But for the matter contained in the part, because it is against nature, it requires to be evacuate by resolving things, as cataplasmes, ointments, fomentations, cupping-glasses; or by evacuation, as by scarifying, or by suppurating things, as by ripening and opening the Impostume. Lastly, for the conjunct accidents, as the Fever, pain and such like, they must be mitigated by asswaging, mollifying and malaxing medicines, as I shall shew more at large hereafter.

CHAP. XXV.

Of the four principall and generall Tumors, and of other Impostumes which may be reduced to them.

The principall and chief Tumors which the abundance of humors generate, are four, a Phlegmon, Erysipelas, Oedema and Scirrhus: innumerable others may be reduced to these, distinguished by divers names according to the various condition of the efficient cause and parts receiving. Wherefore a Phygethlum, Phyma, Fellon, Carbuncle, inflammation of the eyes, Squincy, Bubo, and lastly, all sorts of hot and moist tumors may be reduced to a Phlegmon. The Herpes miliaris, the eating Herpes, Ringwormes and Tetter and all impostumes brought forth by choler, are contained under an Erysipelas. Atheromata, Steatomata, Melicerides, the Testudo, or Talpa, Ganglion, Knots, Kings-Evill, Wens, watery Ruptures, the Ascites and Leucophlegmatia may be reduced to an Oedema, as also all flatulent tumors, which the abundance of corrupt Plegm produces.

In the kindred of the Scirrhus are reckoned a Cancer, Leprosie, Warts, Corns, a Thymus, a Varix, Morphew, black and white, and other Impostumes arising from a Melancholy humor.

Now we will treat of these Tumors in particular, beginning with a Phlegmon.

What tumor may be reduced to a Phlegmon. Which to an Erysipelas. Which to an Oedema.

Which to a Scirrhus.

CHAP. VII.

Of a Phlegmon.

Phlegmon is a generall name for all Impostumes, which the abundance of inflamed blood produces. That is called a true Phlegmon, which is made of laudable blood, offending only in quantity. But a bastard Phlegmon, or a Phlegmonous Impostume hath some other, and proper name; as a Carbuncle, Fellon, Gangrene, Sphacel, and the like malign Pustules. So when there is a conflux of divers humors into one tumor, divers kinds of Phlegmonous Impostumes called by divers names, according to the more abundant humor, arise; as if a small portion of Phlegm shall be mixed with a greater quantity of blood, it shall be called an Oedematous Phlegmon; but if on the contrary, the quantity of phlegm be the greater, it shall be named a phlegmonous Oedema, and so of the rest; always naming the tumor, from that which is predominant in it.

What a true Phlegmon is? A Phlegmon one thing, and a Phlegmonous tumor another.

Therefore we must observe that all differences of such tumors arise from that, either because the blood causing it offends only in quantity; which if it do, it causes that tumor which is properly called a Phlegmon; if in quality, it makes a phlegmonous tumor, because the matter thereof is much departed from the goodness of blood.

But blood is said to offend in quantity, either by admixture of some other matter, as Phlegm, Choler, or Melancholy, from whence proceeds Oedematous, Erysipelous and Scirrhus Phlegmons; or by corruption of its proper substance, from whence Carbuncles, and all kinds of Gangrens; or by concretion, and when nature is disappointed of its attempted and hoped for suppuration, either by default of the air, or patient, or by the error of the Physician; and hence oft times happen Atheroma's, Steatoma's, and Melicerides. Although these things be set down by the Ancients, of the simple and similar matter of the true Phlegmon; yet you must know, that in truth there is no impostume, whose matter exquisitely shews the nature of one, and that simple humor without all admixture of any other matter; for all humors are mixed together with the blood, yet from the plenty of blood predominating, they are called Sanguine, as if they were of blood alone.

Wherefore if any tumors resemble the nature of one simple humor, truly they are not of any naturall humor, but from some humor which is corrupt, vitiated and offending in quality; for so blood by adustion degenerates into choler and melancholy.

Therefore a true Phlegmon is defined by Galen; a tumor against nature, of laudable blood, flowing into any part in too great a quantity.

This tumor though most commonly it be in the flesh, yet sometimes it happens in the bones, as Hippocrates and Galen witness.

A Phlegmon is made and generated thus: when blood flows into any part, in too great a quantity; first the greater veins and arteries of the affected part are filled, then the middle; and lastly, the smallest and capillary; so from those thus distended, the blood sweats out of the pores and small passages like dew; and with this the void spaces which are between the similar parts are first filled, & then with the same blood all the adjacent parts are filled, but especially the flesh, as that which is most fit to receive defluxions, by reason of the spongy rarity of its substance; but then the nerves, tendons, membranes, and ligaments, are likewise stuffed full; whereupon a Tumor must necessarily follow, by reason of the repletion which exceeds the bounds of nature; and from hence also are tension and resistance; and

Gal. lib. de moribus, Cys. ad Glauc. Hippoc. lib. de vuln. cap. Gal. lib. de tumor. prater naturam

pain also happens at the same time, both by reason of the tension and preternaturall heat.

The cause of a bearing Pain in a Phlegmon.

And there is a manifest pulsation in the part, specially whilst it suppurates, because the veins, arteries, and nerves, are much, being they are not only heated within by the influx of the fervid humor, but pressed without by the adjacent parts. Therefore seeing the pain comes to all the foresaid parts because they are two immoderately heated and pressed, the arteries, which are in the perpetuall motion of their *syssole* & *diastole*, whilst they are dilated, strike upon the other inflamed parts, whereupon proceeds that beating pain.

Hereunto add, the Arteries then filled with more copious and hot blood, have greater need to seek refrigeration by drawing in the encompassing Air; wherefore they must as of necessity, have a conflict with the neighbouring parts which are swollen and pained. Therefore from hence is that pulsation in a Phlegmon which is defined by *Galen*, an agitation of the arteries, painfull and sensible to the Patient himself; for otherwise as long as we are in health, we do not perceive the pulsation of the arteries.

Wherefore these two causes of pulsation, or a pulsifick pain in a phlegmon, are worthy to be observed, that is, the heat and abundance of blood, contained in the vessels and arteries (which more frequently than their wont incite the arteries to motion, that is, to their *syssole* and *diastole*) and the compression and straitning of the said arteries, by reason of the repletion and distention of the adjacent parts, by whose occasion the parts afflicted and beaten by the trembling and frequent pulsation of arteries are in pain.

Hence they commonly say, that in the part affected with a Phlegmon, they feel as it were the sense or stroke of a Mallet or Hammer smiting upon it. But also besides this pulsation of the arteries, there is, as it were, another pulsation with itching from the humors whilst they putrefie, and suppurate, by the permixtion, motion, and agitation of vapours, thereupon arising.

The cause of heat in a Phlegmon is blood, which whilst it flows more plentifully into the part, is as it were troden or thrust down, and causes obstruction, from whence necessarily follows a prohibition of transpiration, and a putrefaction of the blood, by reason of the preternaturall heat. But the Phlegmon looks red by reason of the blood contained in it, because the humor predominant in the part shines through the skin.

Another kind of Pulsation in a Phlegmon.

CHAP. XXIII.

Of the causes and signes of a Phlegmon.

The primitive causes of a Phlegmon.

The Antecedent and conjunct.

The signes of a Phlegmon.

The causes of a Phlegmon are of three kinds; for some are primitive, some antecedent, and some conjunct. Primitive are falls, contusions, strains, immoderate labour, frictions, application of acrid ointments, burnings, long staying or labouring in the hot Sun, a diet unconsiderate, and which breeds much blood. The antecedent causes are, the great abundance of blood, too plentifully flowing in the veins. The conjunct, the collection or gathering together of blood impact in any part.

The signes of a Phlegmon are swelling, tension, resistance, feaverish heat, pain, pulsation, (especially while it suppurates) redness, and others, by which the abundance of blood is signified.

And a little Phlegmon is often terminated by resolution; but a great one by suppuration; and sometimes it ends in a Scirrhus, or a Tumor like a Scirrhus; but otherwhiles in a Gangren, that is, when the faculty, and native strength of the part affected, is overwhelmed by the greatness of the defluxion, as it is reported by *Galen*. The Chirurgeon ought to consider all these things, that he may apply and vary such medicines as are convenient for the nature of the Patient, and for the time and condition of the part affected.

Gal. l. de Tum.

CHAP. IX.

Of the cure of a true Phlegmon.

What kind of diet must be prescribed in a Phlegmon.

The Chirurgeon in the cure of a true Phlegmon must propose to himself four intentions. The first of Diet; This, because the Phlegmon is a hot affect and causes a feaver, must be ordained of refrigerative and humecting things, with the convenient use of the six things not naturall, that is, air, meat and drink, motion and rest, sleep and waking, repletion and inanition; and lastly, the passions of the mind. Therefore let him make choise of that air which is pure and cleer, not too moist, for fear of defluxion, but somewhat cool; let him command meats which are moderately cool and moist, shunning such as generate blood too plentifully, such will be broths not too fat, seasoned with a little Borage, Lettuce, Sorrell, and Succory: let him be forbidden the uses of all spices, and also of Garlick, and Onions, and all things which heat the blood, as are all fatty and sweet things, as those which easily take fire. Let the Patient drink small wine, and much allaied with water: or if the feaver be vehement, the water of the decoction of Licoris, Barly, sweet Almonds, or water and Sugar; alwayes having regard to the strength, age, and custome of the Patient.

For

For if he be of that age, or have so led his life, that he cannot want the use of wine, let him use it, but altogether moderately. Rest must be commanded; for all bodies wax hot by motion, but let him chiefly have a care that he do not exercise the part possessed by the phlegmon for fear of a new defluxion. Let his sleep be moderate, neither, if he have a full body, let him sleep by day, specially presently after meat. Let him have his belly soluble; if not by nature, then by art, as by the frequent use of glysters and suppositories. Let him avoid all vehement perturbations of mind, as hate, anger, brawling; let him wholly abstain from venery.

This manner of diet thus prescribed, we must come to the second scope, that is, the diversion of the defluxion, which is performed by taking away its cause, that is, the fulness and illness of the humors. Both which we may amend by purging and blood-letting, if the strength and age of the patient permit.

But if the part receiving be weak, it must be strengthened with those things which by their astringency amend the openness of the passages, the violence of the humor being drawn away by cupping-glasses, frictions, ligatures. But if pain trouble the part, which is often the occasion of defluxion, it must be mitigated by medicines asswaging pain.

The third scope is to overcome the conjunct cause. That we may attain to this, we must enter into the consideration of the tumor, according to its times, that is, the beginning, increase, state, and declination. For from hence the indications of variety of medicines must be drawn. For in the beginning we use repercussives, to drive away the matter of the Phlegmon flowing down, as the white of an Egge, Oxycrate, the juices or waters of Housleek, Plantain, Roses; Cataplasms of Henbane, Pomgranate, Pils, Balausties, Bole armenick, Terra sigillata, oil of Roses, Quinces, Mirtils, Poppies.

Of these simples variety of compound medicines arises. This may be the form of a Cataplasma. *Rx, far. hordei* ℥ iij, *succi semper vivi, plantag. an.* ℥ iij, *pul. malicorii, balaustiorum & rosar. an.* ℥ iij, *ol. mirtill. & rosar. an.* ℥ i. *fiat Cataplasma.* Another, *Rx, Plantag. solani, hyoscyam. an. m. ij. caudæ equin. tapsi barb. centinodæ. an. m. i. coquantur perfecte in oxycrato, pistentur, trajiciantur, addendo pulveris mirtill. nuc. cupressi. & ros. rub. an. ℥ iij. farin. fab. ℥ ij. olei rosar. & cydon. an. ℥ i β, mixe them and make a cataplasma to the form of a liquid pultis. And you may use this liniment, by dipping linnen clothes in it, and applying to the part; *Rx, ol. nymph. & rosar. an. ℥ iij. aq. ros. solani & plantag. an. ℥ iij, aceti ℥ iij, albumin. ovorum n. iij. fiat linimentum.* Also *ung. rosatum & ung. Album, camphor. Rasis* are good to apply to it, as in like manner, *Emp. Diacaltheos* dissolved in vinegar, and oil of Roses, and also *Populeon* may be used. In the increase you must have care of the humor flowing down, and of that which already impacted in the part, did formerly fall down. Therefore repercussives must be tempered and mixed with discussives medicines, but so that they may carry the chief sway, as *Rx, fol. malvæ, absinth. plantag. an. m. iij. coquantur in oxycrato, contundantur, trajectis add farinae fabarum & hordei an. ℥ i. pul. rosar. rub. & Absinth. an. ℥ i, ol. rosar. & chamem. an. ℥ i, fiat cataplasma ad formam pultis satis liquidæ.* Another, *Rx, farinae hord. ℥ iij, farinae sem. lini & fenugreci, an. ℥ i, coquantur in aqua communi, addendo sub finem pul. mirtillorum, rosarum & chamemeli an. ℥ β, axungie anseris & olei rosarum an. ℥ i, misce, fiat cataplasma.**

But in the state the repercussives, and discussives ought to be alike with some anodyne; or mitigating medicines, if it be painful, as *Rx, rad. Altheæ ℥ iiij, malvæ, parietar. ana m. ij, coquantur sub cineribus, addendo farin. fabarum & lentium an. ℥ iij, pulveris chamem. & meliloti an. ℥ β, olei chamem. & rosar. an. ℥ i. axungie gal. ℥ iij, fiat cataplasma.* Another, *Rx, micæ panis triticeæ aqua calida macerati ℥ β, pulveris rosar. rub. & absinth. ana ℥ vi, olei aneth. & mellis com. an. ℥ ij, misce omnia simul & fiat cataplasma ad formam pultis satis liquidæ;* which is of chief use when there is pain.

But when the violence of pain and other symptoms are asswaged, it is likely that the phlegmon is come to determination. Wherefore then we must use more powerfull and strong discussives, and only then beginning with the more gentle, lest the subtiler part of the humor being dissolved, the grosser, remaining in the part, should grow hard, as *Rx, mal. bismal. an. m. iij. coquantur, addendo farinae hordei ℥ ij, mellis com. ℥ i, ol. chamæ. & melilot. an. ℥ β, fiat cataplasma.* Or *Rx, radi cum Brion. & Cucumer. agrest. an. ℥ ij, florum chamem. & melilot. ana m. iij, coquantur in hydromelite addendo farinae, sem. lini & fenugrec. an. ℥ ij. ol. aneth. axungie anser. & anat. an. ℥ i. fiat Cataplasma.* And this plaister following may here find place.

Rx, Diachyl. mag. ℥ ij, Empl. de melilot. ℥ i, olei aneth. & chamemel. an. ℥ β, dissolve them all together and make a medicine for your use. Or Rx, Empl. de mucag. & oxycr. an. ℥ ij. Empl. Diachyl. Ireat. ℥ i, olei liliorum & chamemel. quantum satis est, and make thereof a soft emplaister.

The fourth scope of curing a Phlegmon consists in correction of the accidents which accompany it; of which pain is the principall.

Wherefore the Chirurgion must be diligent to asswage it; for besides, that it weakens the strength, and debilitates and depraves the function, it also causes defluxions by drawing the blood and spirits to the part affected.

According to the variety of pain there must be variety of medicines, as *Rx, micæ panis albi in lacte tepido macerati ℥ β, vitell. ovorum iij, ol. rosar. ℥ ij, croci ℥ β, fiat cataplasma.* Or *Rx, florum chamem. & melil. an. p. iij, farinae sem. lini. & fenugrec. an. ℥ i, fiat cataplasma pultis satis liquidæ.* Or *Rx, mucagin. rad. altheæ & fenugreci an. ℥ iij, ol. rosar. & aneth. an. ℥ i, farin. sem. lini. quantum satis, ut inde formetur cataplasma satis molle.*

How to diversify the defluxion of humors.

The pain must be asswaged.

When we must use repercussives.

What local medicines we must use in the increase.

What in the state.

What in the declination.

The correction of the accidents.

The discommodities of pain. Medicines asswaging pain.

Narcotick medicines.

But if the pain remain, and yeeld not to these remedies, we must flie to stronger, making of narcoticks, or stupefactive, but with care lest we benum, or dead the part; as R \acute{e} , fol. hyoscyani & papaver. sub. cineribus coctorum an. \mathfrak{z} iij, adipis suilla & ol. ros. an. \mathfrak{z} i, croci \mathfrak{D} ij, fiat cataplasma: or R \acute{e} , fol. cicuta & solani furiosi. an. \mathfrak{z} iij, coquantur sub cineribus, pistentur, & trahantur addendo unguent. \mathfrak{z} opul. & ol. rosar. an. \mathfrak{z} i, farin. fænugræc. quantum satis erit ut inde formetur cataplasma ad formam pulvis liquidæ.

CHAP. X.

The cure of an ulcerated Phlegmon.

The signs of a Phlegmon turning to an Abscess.

Ut it often happens that the humor is so impact in the part, that it cannot be repressed, and so gross, that it cannot be discussed; which we may know by the greatness of the heat and swelling, by the bitterness of the pricking pain, the feaver, and pulsation, and heaviness.

Lib. 2 ad Glau. Cap. 7.

Wherefore laying aside all hope of discussing, we must come to the suppuratives. For which purpose Galen foments the swollen part with water, or oil being warm, or with both of them; and then applies this following cataplasim.

Suppurative medicines.

R \acute{e} , farine tric. vel nice panis \mathfrak{z} iij, ol. com. \mathfrak{z} iij. aquæ com. quantum sufficit, fiat cataplasma; Or R \acute{e} , rad. lilior. alb. & altheæ, an. \mathfrak{z} iij, fol. malvæ, parietar. & senecionis ana m. i. coquantur in hydromelite, pistentur trajectis adde farin. sem. lini \mathfrak{z} ij, axunigæ suilla, ol. liliorum an. \mathfrak{z} β , fiat cataplasma: Or R \acute{e} , malvæ, bisnalu. violar. an. m. i. caricarum ping. u. x. passul. \mathfrak{z} ij, coquantur in aq. com. tufis, & trajectis, adde mellis com. \mathfrak{z} ij, ung. basilicon. & butyri recent. ana \mathfrak{z} i, fiat cataplasma. You may profitably use for the same purpose Empl. Diachylon magnum, or Basilicon. Or R \acute{e} , Empl. Diachyl. Mag. \mathfrak{z} iij, ung. basilicon. \mathfrak{z} i. ol. liliorum \mathfrak{z} β . Of these mixed together make a medicine for the foresaid use.

The signs of pus or matter.

When the heat, pain, feaver, and other accidents shall remit, when the tumor hath a sharpe head, when by the pressing of your finger you find the humor to flow as it were to and fro, then you may know that it is ripe.

Wherefore without any further delay the tumor must be opened, lest the matter too long shut up, corrode the adjacent parts, and the ulcer become sinuous and fistulous.

For this usually happens, especially then, when the matter is venenate or malign, or when the swelling is near a joint, or at the fundamenn, or such like hot and moist places.

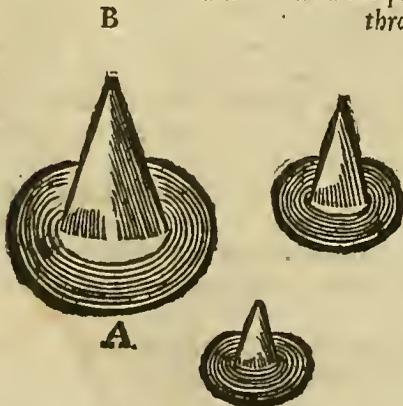

Hip. lib. de Fistula.

For by the decree of Hippocrates we should anticipate the maturation of such tumors by opening.

They may be opened with an incision knife or caustick, and that either actually or potentiall. For if the Patient shall be heartless and less confident, so that he either cannot, or will not indure any instrument, you must make way for the matter by a potentiall cautery. You may also do the business by another slight, as thus.

Thrust the point of a sharpe knife or lancet, through a brass counter that it may stand fast in the midst thereof; then cover it diligently with some Emplaster or Cataplasim, that neither the Patient nor standers by perceive the deceit: then laying on the plaister as that you would make a passage for the matter by that means, but when you have fitted the point to the part, where it is fit to open the tumor, so guide the Counter with your fingers, that you may presently make an impression into the Tumor, sufficient for excluding the matter. I have here expressed three delineations of such Instruments that you may use these, either bigger, lesser or indifferent, as occasion shall serve.

Counters with the points of Knives or Launces put through them.

A. shews the Counter or peece of Silver.
B. shews the point of the Lancet.

But there are seven things which must be diligently considered in opening all sorts of Inpostumes. The first is, that you put your knife to that part of the Abscess which is the softer, and yeelds to the impression of your fingers, and where it rises into a head, or point.

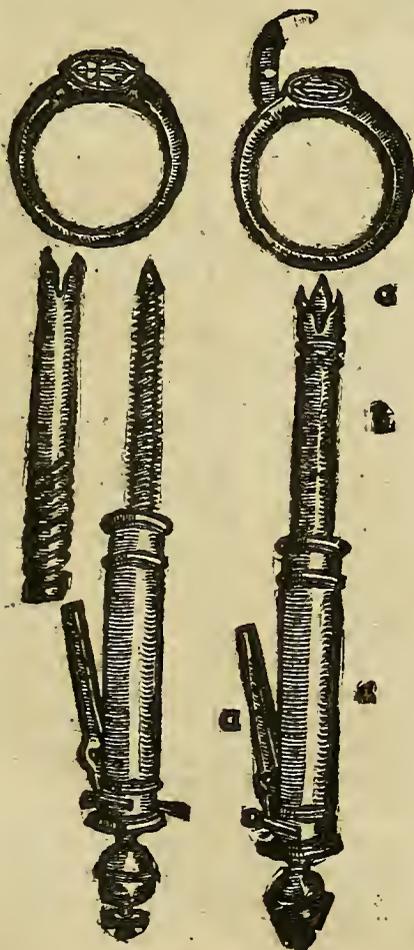

point. The second is, that you make choise of that place for dissection which is the lowest, that so the contained impuritie may the more readily flow out, and not stay in the passage. The third is, that it be made according to the wrinkles of the skin, and the right fibers of the Muscles lying next under the skin. The fourth is, that you turn your knife from the larger vessels and Nerves worth speaking of. The fifth is, that the matter contained in them be not evacuated too abundantly at once in great Abscesses, lest thereby the strength be dejected, the spirits being much wasted together with the unprofitable humor. The sixth is, that the affected part be handled as gently as you can. The seventh is, that after the opening when the matter is evacuated, the Abscess be cleansed, filled with flesh, and lastly, consolidated and cicatrized. But seeing that commonly after such sections some part of the Tumor remains, all the contained humor being not wholly suppurated, the Chirurgion may perceive that this is an implicate affect, that is, a Tumor and Ulcer. But the Cure thereof must be so, that you take away the Tumor before the Ulcer; for the Ulcer cannot be healed before the part be restored to its nature. Therefore the suppuratives formerly prescribed must be used, and the Ulcer must be dressed for two or three dayes with this following Medicine.

℞ Vitellum unius ovi, terebinth. Venet. & ol. Rosar. an. ℥ β, fiat medicamentum. Then you must seek to cleanse it by this following Medicine.

℞ Mellis rosar. ℥ i, Syrupi rosar. & tereb. Venet. an. ℥ i β, far. hordei ℥ ij, fiat medicamentum ad usum. For this very purpose there is a singular Deterfive made of *Appium* or Smallage of which this is the description.

℞ Succu appii, plantag. beton. an. ℥ i, Mellis commun. ℥ v, terebinth. Venet. ℥ iiij, farin. Hordei & Orobi, an. ℥ ij, pulveris Aloes, rad. Ireos florent. myrrh. an. ℥ i, coquatur mel. cum succis quibus consumptis addantur farine & pulveres, & misceantur omnia ad formam unguenti. But if you would cleanse it more powerfully, you may use *Vnguentum Apostolorum*, or *Vnguentum Aureum* and *Ægyptiacum* mixed according to the scope you conceive in your minds; when the Ulcer shall seem sufficiently clenfed, it shall be filled with flesh and cicatrized after the manner we shall declare in the proper treatise of the cure of Ulcers.

Other Instruments for opening Abscesses.

Rings in which little knives lyē hid, fit for to open Abscesses.

The Delineation of a Truske or hollow Instrument going with a spring.

- A. Shews the thicker pipe.
- B. Shews another which enters and is fastened in the other by a screw.
- C. The point of the Instrument looking out.
- D. The spring which forces the Instrument.

What the cure must be after the opening of the abscess

Deterfive Medicines; Vnguentum de Appio.

CHAP. XI.

Of feavers, and the cures of these feavers which accompany Phlegmons.

The Feaver of
a Phlegmon.
What a Feaver
is.

Mongst the *Symptoms* which most usually accompany Phlegmons, and afflict all the body of the patient, Feavers are the chief; that is, hot, and dry distempers kindled in the heart, and thence by the Artery is sent over all the body; yet these which usually follow this kind of Tumors are *Ephemeræ*, that is, *Diary*, unputrid *Synochi*;

Of whose nature and order of cure I will here briefly relate what I have learnt from my Masters; that is, Doctors of Physick, as I have been conversant with them in the practise of my Art.

What an *Ephemeræ*, or *Diary* is.

The *Ephemeræ*, or *Diary* [that is, of one day] is a hot and dry distemperature kindled in the vitall spirits. It hath that name, because by its own nature it carries not above the space of one day or twenty four houres, by reason it is kindled in a subtile easily dissipable matter.

The causes thereof.

The efficient causes of this Feaver are wearines, hunger, and drunkenness, anger, fury, sorrow, watching, great & piercing cold, Aduotion, Bathes, and manner of living inclining more to heat than ordinary, applying, using or drinking of acrid medicines, as Poysons, or of hot meats, or drinks; to conclude, all the efficient causes common to all Feavers, putrefaction only excepted which properly appertains to putrid feavers.

Aphorism. 55.
lib. 4.

For a *Bubo* also, which is a *Phlegmon* of the Glandules, causes a *Diary*, as *Hippocrates* shews. All feavers proceeding from the Tumors of the Glandules are evill, the *Diary* excepted. Which *Aphorism* must be understood warily and with that distinction which *Galen* gives in his commentary, where he saith; It is only to be understood of Tumors rising in the Glandules without occasion, that is, without any evident and manifest cause; for otherwise Feavers that thence take their originall, though not *Diary*, yet are not all evill, as we learn by *Buboes* in Children, and the venereous *Buboes*, which happen without inflammation, or corruption of the liver; for such commonly have no malign Feaver accompanying them, which thing is worthy a Chirurgeons observation.

The signs of a *Diary*.

The common signs of a *Diary* are, a moderate and vaporous heat feeling gentle to the hand, a pulse swift and frequent, sometimes great and strong, as when the *Diary* is caused by anger; sometimes little; if the Feaver proceed from sorrow, hunger, cold, crudity; for other respects equal and ordinary.

Why in a *Diary* the urines like to these in health.

The most certain signs are, if the Feaver come upon one not by little and little but suddenly and that from some externall and evident cause, no loathing of meat, no causeless weariness, no deep sleep, yawning, great pain, restlessness, shaking nor cold going before, and lastly, no other troublesome symptome preceding. We here make no mention of the urine, because most frequently they resemble the urines of sound bodies; for in so short a time as *Diaries* endure, there cannot so great a perturbation be raised in the blood that there may be signes thereof found in the urine. A *Diary* is ended in one fit, which by the proper nature of this Feaver lasts but one day, although sometimes, otherwise it is extended to three, or four dayes space; and then it easily degenerates into a *Putrid*, especially any error of the Patient, Physitian, or those which attend him concurring therewith, or if the externall things be not rightly fitted.

The unputrid *Synochus*.

This Feaver is terminated either by insensible transpiration, or by the moisture of the skin, or by a sweat naturall, gentle, and not ill smelling; to this *Diary* we may refer the unputrid *Synochus* generated of blood not putrid, but only heated beyond measure. For usually there arises a great heat over all the body, by means of the blood immoderately heated; whence the veins become more tumid, the face appears fiery, the Eyes red and burning, the breath hot, and to conculde, the whole habit of the body more full, by reason of that ebullition of the blood, and the diffusion of the vapours thence arising over all the body: Whence it is, that this kind of *Synochus* may be called, a vaporous Feaver. To this Children are incident as also all sanguine bodies, which have no ill humors. The cure of this and the *Ephemeræ* or *Diary* is the same; because it may scarce seem different from the *Ephemeræ* in any other thing, than that it may be prolonged for three or four dayes. Wherefore whatsoever we shall say for the cure of the *Ephemeræ*, may be applied to the *Synochus*, blood-letting excepted, which in an unputrid *Synochus* is very necessary.

The cure of a *Diary* Feaver.

Now the cure of a *Diary* Feaver consists in the decent use of things not natural, contrary to the cause of the disease; wherefore bathes of warm and naturall water are very profitable; so that the Patient be not Plethorick, nor stult with excrements, nor obnoxious to catarrhes and defluxions, because a catarrh is easily caused and augmented by the humors diffused and dissolved by the heat of a bath; therefore in this case we must eschew frictions, and anointing with warm oil, which things notwithstanding are thought very usefull in these kinds of Feavers, especially when they have their originall from extreme labour, by astriction of the skin or a *Bubo*. Let this be a generall rule, that to every cause, whence this Feaver proceeded, you oppose the contrary for a remedy; as to labour, rest; to watching, sleep; to anger and sorrow, gratefull society of friends, and all things replenished

plentiful with plearant good will; and to a *Bubo*, the proper cure thereof.

Wine moderately tempered with water according to the custome of the sick patient, is good and profitable in all causes of this Feaver; except he be pained in his head, or that the Feaver drew its originall from anger, or a *Bubo*; for in this last case especially, the patient must abstain wholly from wine, untill the inflammation come to the state, and begins to decline. This kind of Feaver often troubles infants; and then you must prescribe such medicines to their Nurses, as if they were sick, that so by this means their milk may become medicinal. Also it will be good to put the Infant himself into a bath of naturall and warm water, and presently after the bath to anoint the ridge of the back and breast with oyl of Violets. But if a *Phlegmon* possess any inward part; or otherwise by its nature be great; or seated near any principall Bowel; so that it may continually send from it either a putrid matter or exhalation to the heart, and not only affect it by a quality or preternaturall heat by the continuity of the parts, thence wil arise the putrid *Synochus*, if the blood by contagion putrefying in the greater vessels, consists of one equall mixture of the four humors. This Feaver is thus chiefly known, it hath no exacerbations, or remissions, but much less intermissions; it is extended beyond the space of twenty four houres, neither doth it then end in vomit, sweat, moisture, or by little and little by insensible transpiration; after the manner of intermitting Feavers, or Agues; but remains constant, untill it leaves the patient for altogether; it commonly happens not unless to these of a good temper and complexion, which abound with much blood, and that tempered by an equall mixture of the four humors. It commonly indures not long, because the blood by some peculiar putrefaction degenerating into cholera or Melancholy, will presently bring forth another kind of Feaver, to wit, a Tertian or continued Quartain.

The cure of this Feaver (as I have heard of most learned Physicians) chiefly consists in bloodletting. For by letting of blood the fulness is diminished, and therefore the obstruction is taken away, and lastly, the putrefaction. And seeing that in this kind of Feaver there is not only a fault of the matter, by the putrefaction of the blood, but also of the Temper by excess of heat; certainly Phlebotomy helps not only, as we said, the putrefaction, but also the hot distemper. For the blood in which all the heat of the creature is contained; whilst it is taken away, the acrid and fuliginous excrements exhale and vanish away with it, which kept in, encreased the Feaverish heat. Moreover, the veins, to shun emptiness, which nature abhors, are filled with much cold air in stead of the hot blood which was drawn away, which follows a cooling of the habit of the whole body; yea and many by means of Phlebotomy have their bellies loosed, and sweat; both which are much to be desired in this kind of Feaver.

This moved the ancient Physicians, to write, that we must draw blood in this disease, even to the fainting of the Patient.

Yet because thus, not a few have poured out their lives together with their blood, it will be better and safer to divide the evacuations; and draw so much blood as severall times, as the greatness of the disease shall require, and the strength of the Patient may bear.

When you have drawn blood, forthwith inject an emollient and refrigerative clyster; lest that the veins emptied by Phlebotomy may draw into them the impurity of the Guts; but these clysters which cool too much, rather bind the belly, than loose it. The following day the Morbifick matter must be partly evacuated by a gentle purge, as a bole of *Cassia*, or *Catholicon*; then must you appoint Syrups which have not only a refrigerative quality, but also to resist putrefaction, such as the Syrup of Lemmons, Berberries, of the Juice of Citrons, of Pomgranats, Sorrell and Vineger; let his diet be absolutely cooling and humecting, and also slender; for the native heat much debilitated by drawing of a great quantity of blood cannot equall a full diet. Therefore it shall suffice to feed the Patient with chicken and veal broths made with cooling herbs, as Sorrell, Lettuce, and Purslain. Let his drink be Barly water, Syrup of Violets mixed with some pretty quantity of boiled water, *Julepum Alexandrinum*, especially if he be troubled with scouring, or laske. But the Physician must chiefly have regard to the fourth day; for if then there appear any signs of concoction in the excrements, the *Crisis* must be expected on the eventh day, and that either by a loosness of the belly, or an abundance of urine, by vomits, sweats, or bleeding. Therefore we must then do nothing but commit the whole business to nature.

But for drinking cold water, which is so much commended by *Galen* in this kind of Feaver, it is not to be suffered before there appear signs of concoction; moreover in the declining of the disease the use of wine will not be unprofitable to help forwards sweats.

The use of wine in a Diet.

CHAP. XII.

Of an Erysipelas, or Inflammation.

The definition
of an Erysipe-
las.

Having declared the cure of a Phlegmon, caused by laudable blood, we must now treat of these tumors which acknowledge choler the material cause of their generation, by reason of that affinity which intercedes between Choler and Blood. Therefore the tumors caused by naturall Choler, are called *Erysipelata*, or Inflammations; these contain a great heat in them, which chiefly possesses the skin, as also oftentimes some portion of the flesh lying under it. For they are made by most thin and subtle blood (which upon any occasion of inflammation easily becomes cholerick) or by blood and choler, hotter than is requisit, and sometimes of choler mixed with an acrid serous humor.

Gal. Cap. 2. lib.
14. Meib. med.
Cy 2. ad Glau.

That which is made by sincere and pure choler, is called by *Galen*, a true and perfect *Erysipelas*. But there arise three differences of *Erysipelaes* by the admixture of choler with the three other kinds of humors. For if it being predominant be mixed with blood, it shall be termed *Erysipelas Phlegmonodes*; if with Phlegm, *Erysipelas adematodes*; if with Melancholy, *Erysipelas Scirrholes*. So that the former and substantive word shews the humor bearing dominion, but the latter or adjective that which is inferior in mixture. But if they concur in equall quantity, there will be thereupon made *Erysipelas Phlegmone*; *Erysipelas adema*, *Erysipelas Scirrhus*.

Two kinds of
Erysipelas.

Galen acknowledges two kinds of *Erysipelaes*, one simple and without an ulcer, the other ulcerated. For choler drawn & severed from the warmnes of the blood, running by its subtlety and acrimony unto the skin, ulcerates it; but restrained by the gentle heat of the blood, as a bridle, it is hindered from piercing to the top of the skin, and makes a tumor without an ulcer. But of unnaturall choler are caused many other kinds of cholerick tumors, as the *Herpes exedens*, and *Miliaris*, and lastly, all sorts of tumors which come between the *Herpes* and *Cancer*. You may know *Erysipelaes* chiefly by three signs, as by their colour, which is a yellowish red; by their quick sliding back into the body at the least compression of the skin (the cause of which is the subtlety of the humor and the outward site of it under the skin, whereupon by some an *Erysipelas* is called a Disease of the skin;) Lastly, by the number of the Symptoms, as heat, pulsation, pain. The heat of an *Erysipelas* is far greater than that of a Phlegmon, but the pulsation is much les; for as the heat of the blood is not so great, as that of choler, so it far exceeds choler, in quantity and thickness, which may cause compression and obstruction of the adjacent muscle.

Gal. lib. 2. ad
Glauc.

Hip. Apho. 79.
Sect. 7.
Aph. 25.
Sect. 16. Aph.
43. Sect. 3.

For Choler easily dissipable by reason of its subtlety quickly vanishes, neither doth it suffer it self to be long contained in the empty spaces between the muscles; neither doth an *Erysipelas* agree with a Phlegmon in the propriety of the pain. For that of an *Erysipelas* is pricking and biting without tension, or heaviness, yet the primitive, antecedent, and conjunct causes are alike of both the tumors. Although an *Erysipelas* may be incident to all parts, yet principally it assails the face, by reason of the rarity of the skin of that place, and the lightness of the cholerick humor flying upwards. It is ill when an *Erysipelas* comes upon a wound, or ulcer; and although it may come to suppuration, yet it is not good; for it shews that there is obstruction by the admixture of a gross humor, whence there is some danger of erosion in the parts next under the skin.

It is good when an *Erysipelas* comes from within outwards; but ill when from without it retires inward. But if an *Erysipelas* possess the womb it is deadly, and in like manner if it spread too far over the face, by reason of the sympathy of the membranes of the brain.

CHAP. XIII.

Of the cure of an Erysipelas.

Gal. 14.
Meibed.

Nor the cure of an *Erysipelas* we must procure two things, to wit, evacuation and refrigeration. But because there is more need of cooling, than in a Phlegmon, the chief scope must be for refrigeration. Which being done, the contained matter must be taken away and evacuated with moderately resolving medicines. We must do four things to attain unto these forementioned ends.

4 Things to be
performed
in cutting an
Erysipelas.

First of all we must appoint a convenient manner of Diet, in the use of the six things not naturall; that is, we must incaffate, refrigerate and moisten as much as the nature of the disease and patient will suffer, much more than in a Phlegmon; then we will evacuate the Antecedent matter, by opening a vein, and by medicines purging choler. And that by cutting the Cephalick vein, if there be a portion of the blood mixed with Choler, if the *Erysipelas* possess the face, and if it be spread much over it.

In what
Erysipelas it is
convenient to
let blood, in
what not.

But if it shall invade another part, although it shall proceed of pure choler, Phlebotomy will

will not be so necessary, because the blood which is as a bridle to the choler being taken away, there may be danger, lest it become more fierce; yet if the body be plethorick, it will be expedient to let blood, because this, as *Galen* teacheth, is oft times the cause of an *Erysipelas*. It will be expedient to give a clyster of refrigerating and humecting things before you open a vein; but it belongs to a learned and prudent Physitian to prescribe medicines, purging choler.

The third care must be taken for Topick, or locall medicines, which in the beginning and encrease must be cold and moist, without any either dryness or astringent, because the more acrid matter by use of astringent things being driven in, would ulcerate and fret the adjacent partick.

Galen and *Avicen* much commend this kind of remedy; Take fair water ℥vi, of the sharpest Vinegar ℥i, make an Oxycrate, in which you may wet linnen clothes and apply to the affected part and the circumjacent places, and renew them often. Or R̄, *Succi solani, plantag. & sempervivi, an. ℥ij, aceti ℥β, Mucaginis sem. Pylly ℥ij, succi hyoscyami ℥i, Misce.* But if the *Erysipelas* be upon the face, you must use the medicine following.

R̄, *Unguent. Roj. ℥iiij, succi plantagin. & sempervivi, an. ℥i, trochisc. de Camphora ℥β, aceti parum;* let them be mixed together and make a liniment. But if the heat and pain be intolerable, we must come to narcotick medicines. As R̄, *succi hyoscyami, solani, cicutæ, an. ℥i, album. ovorum n. ii, aceti ℥β, opii & Camphor. an. gra. 4, croci ℥β, Mucaginis sem. psyll. & semigr. extractæ in aq. ros. & plantag. an. ℥i, ol. de papav. ℥ij. fiat linimentum, addendo ung. refrigerantis Gal. camphor. q. satis sit.* Yet we must not use such like medicines too long, lest they cause an extinction of the native heat and mortification of the part.

Wheretore such Narcotick medicines must be used with regard of place, time and such other circumstances. Therefore we may three manner of wayes understand when to desist from using Narcotick or stupefactive medicines. The first is when the Patient in the affected part feels not so much heat, pricking and pain, as before; The second is when the part feels more gentle to the touch than before; The third when the fiery and pallid colour begins by little and little to waxe livid and black; for then must we abstain from Narcotick, and use resolving and strengthening things, whereby the part may be revived and strengthened by recalling the Native heat; As R̄, *Farinæ hordei & Orobi, an. ℥ij, farinæ sem. lini ℥i β, coquantur in Hydromelite vel oxycrato, addendo pulv. rosarum & chamemel. an. ℥β, ol. anethi & chamem. an. ℥i, fiat cataplasma.* Or you may use this following fomentation, R̄, *Rad. Altheæ ℥ij, fol. malvæ, bismal. pariet. absinthii, salviæ, an. m. i, flor. chamem. meliloti, rosar. rub. an. m. ij, coquantur in aquis partibus vini & aquæ, & fiat satus cum spongia.* After the fomentation you may apply an Emplaster of *Diachylon Ireatum*, or *Diapalma* dissolved in oil of chamomile and Melilote, and such other like. The fourth Intention which is of the correction of accidents, we will perform by these means which we mentioned in curing a Phlegmon, by varying the medicaments, according to the judgment of him which undertakes the cure.

What to pick medicines are fit to be used in the beginning of an *Erysipelas*;

What caution must be had in the use of narcotick medicines.

Resolving and strengthening medicines.

CHAP. XIII.

Of the Herpes; that is, Teaters, or Ringwormes, or such like.

Herpes is a tumor caused by pure choler separated from the rest of the humors, that is carried by its naturall lightness and tenuity even to the outer or scarce skin, and is diffused over the surface hereof. *Galen* makes three sorts of this tumor. For if perfect choler of an indifferent substance, that is, not very thick, cause this tumor, then the simple *Herpes* is generated, obtaining the name of the *Genus*; but if the humor be not so thin, but compounded with some small mixture of Phlegm, it will raise little blisters over the skin like to the seeds of Millet, whence it was that the Ancients called this Tumor the *Herpes Miliaris*. But if it have any admixture of Melancholy, it will be an *Herpes exedens*, terrible by reason of the erosion or eating into the skin and muscles lying under it.

These are absolutely three intentions of curing; The first is to appoint a Diet just like that we mentioned in the cure of an *Erysipelas*; The second is to evacuate the antecedent cause, by medicines purging the peccant humor, for which purpose oft-times clysters will suffice, especially if the patient be somewhat easie by nature, and if the urine flow according to your desire; for by this a great part of the humor may be carried into the bladder; The third shall be to take away the conjunct cause by locall medicines ordained for the swelling and ulcer: Therefore the Chirurgeon shall have regard to two things, that is, the resolving of the tumor, and the drying up of the ulcer; for every ulcer requires drying, which can never be attained unto, unless the swelling be taken away. Therefore because the chiefest care must be to take away the Tumor, which unless it be performed there can be no hope to heal the ulcer, he shall lay this kind of medicine to dissolve and dry, as R̄ *Ceruse & tuthie prepar. an. ℥i, ol. ros. & adipis capon. an. ℥ij, corticis pini usti, & loci, ℥β, cereæ quantum satis, fiat unguentum.* Or R̄, *Farin. hordei & lent. an. ℥ij, coquantur in decocto corticis*

What a *Herpes* is, what be the kinds thereof.

Gal. 2. ad Glauconem. What the *Herpes miliaris* is.

What the *exedens*.

Three intentions in curing *Herpes*.

Mercurio.
Medicines fit
for restraining
eating and
spreading
ulcers.

mali granati, balaust. plantag. addendo pulveris rosar. rub. absinth. an. ʒ β, olei Myrtillor. & mellis com. an. ʒ vi, fiat unguentum, ut artis est. But for an *Herpes Miliaris* these must chiefly be used, *Res. pulv. gallarum, malicuri, balaust. boli armeni an. ʒ i, aquæ ros. ʒ iij, aceti acerrimi ʒ i, axungie anser. & olei Myrtillor. an. ʒ i β, terebinth. ʒ i, fiat unguentum ad usum.* I have often found most certain help in *unguentum enulatum cum Mercurio*, for it kills the pustules, and partly waists the humor contained in them. Yet if the ulcer, not yett neither yeelds, but every day diffuses it self further and further, you shall touch the edges and lips thereof with some acrid medicine, as *Aqua fortis*, oyl of Vitriole, or such like, for by this kind of remedy, I have oft times healed fretting ulcers, which seemed altogether incurable.

CHAP. XV.

Of Feavers, which happen upon Erysipelous Tumors.

A vulgar de-
scription of an
intermitting
Tertian feaver.

S Feavers sometimes happen upon Inflammations, and Erysipelaes, which favour of the humor whereof they proceed, that is, Choler. Therefore seeing it is peculiar to Choler, to move every third day, it is no marvail if great Inflammations bring with them Tertian Feavers, or Agues, which have their fit every third day; for it is called an Intermitting Tertian which comes every other day.

The causes of
Tertian fea-
vers.

The Primitive causes; in generall are strong exercises, especially in the hot Sun, the use of heating, and drying either meats or medicines, great abstinence joyned with great labour, care, sorrow; the antecedent causes are the plenty of choler in the body, an hot and dry disposition either of the whole body, or of the liver only: the conjunct cause is the putrefaction of the cholerick humor lying in some plenty without the greater vessels, in the habit of the body.

The signs of an
intermitting
Tertian.

The signs, a shaking or shivering like as when we have made water in a cold winter morning, a great pricking, stretching, or stiffness, as if there were pins thrust into us over all our bodies, by reason of the acrimony of the cholerick humor driven uncertainly and violently over all the body, and the sensible membranous and nervous particles at the beginning of the fit; then presently the heat becomes acrid, the Feaver kindled, like a fire in dry straw; the pulse is great, quick and equal; the tongue dry; the urine yellowish, red and thin. The Symptoms are watchings, thirst, talking idly, anger, disquietness and tossing the body at the least noise or whispering. These Feavers are terminated by great sweats. They are incident to cholerick young men, such as are lean, and in Summer; after the fit oft times follow cholerick vomiting and yellowish stools. After the fit there follows an absolute intermission retaining no reliques of the Feaver, untill the approach of the following fit, because all the cholerick matter by the force of that fit and nature is easily cast out of the body, by reason of its naturall levity and facility; whereas in Quotidians there is no such thing, as which after the fit always leave in the body a sense and feeling of a certain inequality by reason of the stubbornness of the Phlegmatick humor, and dulnes to motion. The fit commonly uses to endure 4, 5, or 6 houres, although at some time it may be extended to 8 or 10. This Feaver is ended at 7 fits, and usually is not dangerous, unless there be some error committed by the Physitian, Patient, or such as attend him. Tertians in summer are shorter, in winter longer.

The Sym-
tomes

Why Tertians
have an abso-
lute cessation
of the feaver at
the end of each
fit,

Wherefore the beginning of the fit is accompanied with stiffness, or stretching, the state with sweat, whereupon if the nose, lips or mouth break forth into pimples or scabs, it is a sign of the end of the Feaver, and of the power of nature which is able to drive the conjunct cause of the disease from the center to the habit of the body; yet these pimples appear not in the declining of all Tertians, but only then, when the cholerick humor causing the Feaver shall reside in the stomach, or is driven thither from some other part of the first region of the Liver. For hence the subtler portion thereof carryed by the continuation of the inner coat to the mouth and nose, by its acrimony easily causes pimples in these places. The cure is performed by Diet, and Pharmacy.

The diet of
such as have a
Tertian.

When such as
have a tertian
may use wine.

The time of
feeding the
patient.

Therefore let the Diet be so ordered for the six things not naturall, that it may incline to refrigeration and humectation, as much as the digestive faculty will permit, as Lettuce, Sorrel, Gourds, Cowcubers, Mallows, Barly Creams, Wine much allaid with water, thin, small, and that sparingly and not before signs of concoction shall appear in the urine; for at the beginning he may not use wine, nor in the declining, but with these conditions, which we have prescribed.

But for the time of feeding the patient, on that day the fit is expected, he must eat nothing for three houres before the fit, lest the aguish heat lighting on such meats as yett crude, may corrupt and putrefie them; whence the matter of the Feaver may be increased, (because it is as proper to that heat to corrupt all things, as to the native to preserve and vindicate from putrefaction) the fit lengthened, and nature called away from the concoction and excretion of the Morbifick humor; yet we may temper the severity of this law by having regard to the strength of the patient; for it will be convenient to feed a weak patient not only before the fit, but also in the fit it self, but that only sparingly, lest the strength should be too much impaired.

Now

Now for Pharmacy; It must be considered, whether the strength of the Patient be sufficient, if the humors abound; for then you may prescribe *Diaprunum simplex*, *Cassia* newly extracted, the decoction of Violets, of Citrin Myrobalanes; Syrups of Violets, Roses, of Pomegranats and Vineger. But if the powers of the Patient languish, he must not only not be purged, but also must not draw blood too plentifully, because Cholerick men soon faint, by reason of the facile and easie dissipation of the subtle humors and spirits; besides such as are subject to tertian Feavers do not commonly abound with blood, unless it be with Cholerick blood, which must rather be rentied, or amended by cooling and humecting things, than evacuated. Yea verily, when it is both commodious and necessary to evacuate the body, it may be attempted with far more safety by such things as work by insensible transpiration, which provoke sweats, vomit or urine by reason of the subtlety of the Cholerick humor, than by any other. Also the frequent use of emollient glysters made with a decoction of Prunes, Jujubes, Violets, Bran and Barley, will profit much. If the Patient fall into a *Delirium* or talk idly by reason of the heat and dryness of the head, with a particular excess of the cholerick humor, the Head must be cooled by applying to the Temples and Forehead and putting into the Nose oyl of Violets, Roses, or womans milk. Let the feet and legs be bathed in fair and warm water, and the soles of the feet be anointed with oyl of Violets and such like.

When to
purge the
patient.

In the declining, a Bath made of the branches of Vines, the leaves of Willows, Lettuce and other refrigerating things boiled in fair water, may be profitably used three hours after meat eaten sparingly.

But I would have you so to understand the Declination or declining not of one particular fit, but of the disease in generall, that the humors already concocted, allured to the skin by the warmth of the bath, may more easily and readily breath forth: he which otherwise ordains a bath at the beginning of the disease, will cause a constipation in the skin and habit of the body, by drawing thither the humors peradventure tough and gross, no evacuation going before.

When the time
is fit to use a
Bath.

Also it will be good after generall purgations to cause sweat by drinking White wine thin and well tempered with water; but urine by a decoction of Smallage and Dill; Certainly sweat is very laudable in every putrid Feaver, because it evacuates the conjunct matter of the disease, but chiefly in a Tertian, by reason that choler by its inbred levity easily takes that way, and by its subtilty is easily resolved into sweat. But that the sweat may be laudable it is fit it be upon a criticall day, and be foresheved by signs of concoction agreeable to the time and manner of the disease. Sweats when as they flow more slowly are forwarded by things taken inwardly and applied outwardly; by things taken inwardly, as with white wine, with a decoction of Figs, Raisins stoned, grasse roots and the like opening things; but by things outwardly applied, and sponges dipped in a decoction of hot herbs (as Rosmary, Time, Lavander, Marjerom and the like) applied to the Groins, Armholes, and ridge of the back.

What kinds of
evacuatiions are
most fit in a
Tertian.

Sudorificks,

You may for the same purpose, fill two Swines bladders with the same decoction, or else stone bottles, and put them to the feet, sides, and between the thighs. Then let this be the bound of sweating, when the Patient begins to waxe cold; that is, when the sweat feels no more hot, but cold.

But by the consent of all, blood must not be letten after the third fit, but presently at the beginning of the Feaver, according to the opinion and prescription of *Galen*; for seeing this Feaver for the most part is terminated at seven fits, if you stay untill the third fit be past, the Feaver will now be come to its state; but *Hippocrates* forbids us to move any thing in the state, lest nature then busied in concocting the disease, be called from its begun enterprise.

When blood
must be let.

Aphor. 29.
Sect. 2.

CHAP. XVI.

of an Oedema or cold Phlegmatick Tumor.

Hitherto we have treated of hot Tumors, now we must speak of cold; Cold Tumors are only two, an *Oedema* and a *Scirrhus*; And for all that *Hippocrates* and the Ancients used the word *Oedema* for all sorts of Tumor, in generall; yet by *Galen* and these Physitians, which succeeded him, it hath been drawn from that large and general signification, to a more strait and speciall, only to designe a certain species, or kind of Tumor.

Gal. lib. de tumo-
ra præter naturæ.

Wherefore an *Oedema* is a soft, laxe and painlesse Tumor, caused by collection of a Phlegmatick humor.

What an
Oedema is.

The Ancients made eight differences of Tumors proceeding of Phlegm: The first they termed a true and lawfull *Oedema* proceeding from naturall Phlegm; from unnaturall phlegm by admixtion of another humor they would have three sorts of Tumors to arise, as

The differ-
ences of Oedema.

that by mixture of blood, should be made an *Oedema Phlegmonodes*, and so of the rest.

Besides, when they perceived unnaturall Phlegm either puffed up by flatulency, or to flow with a waterish moisture, they called some *Oedemaes* flatulent, others waterish; but also when they saw this same Phlegm often to turn into a certain Plaister-like substance, they thought that hence proceeded another kind of *Oedema*, which they expressed one while by the name of *Atheroma*, another while by *Steatoma*, and sometimes by *Melicerides*, as lastly, they called that kind of *Oedema* which is caused by putrid and corrupt slegm, *Scrophule*. For we must observe that Phlegm sometimes is naturall, and offends only in quantity, whence the true *Oedema* proceeds; otherwhiles it is not naturall; and it becomes not naturall, either by admixtion of a strange substance, as bloud, Choler or Melancholy, whence arise the three kinds of *Oedema's* noted formerly by the way; or by the putridness and corruptions of its proper substance, whence the *Strumæ* and *Scrophule* proceed; or by concretion, whence kernels and all kinds of Wens, *Ganglia* and knots; or by resolution, whence all flatulent and waterish Tumors, as the *Hydrocele*, *Pneumatocèle* and all kinds of Dropsies.

By how many waies Phlegm becomes not naturall.

The Causes.

The causes of all *Oedema's* are the defluxion of a Phlegmatick or flatulent humor into any part, or the congestion of the same made by little and little in any part, by reason of the imbecillity thereof in concocting the nourishment, and expelling the excrement.

The signs.

The signs are a colour whitish and like unto the skin, a soft Tumor, rare and laxe by reason of the plentiful moisture with which it abounds, and without pain, by reason this humor inters no sense of heat nor manifest cold; when you press it with your finger the print thereof remains, because of the grossness of the humor and slowness to motion. *Oedema's* breed rather in winter than in summer, because winter is fitter to heap up Phlegm; they chiefly possess the Nervous and Glandulous parts, because they are bloudless, and so cold and more fit by reason of their looseness to receive a defluxion; for the same cause bodies full of ill humors, ancient, and not exercised, are chiefly troubled with this kind of Tumor.

The progno-
sticks.

How *Oedema's*
are terminated.

An *Oedema* is terminated sometimes by resolution, but oftner by concretion, seldomer by suppuration, by reason of the small quantity of heat in that humor.

A Symptomatically *Oedema*, as that which follows upon a Dropsie or Consumption, admits no cure unless the disease be first taken away.

The intentions
of curing *Oede-
ma's*.
The diet.

The generall cure is placed in two things, that is, in evacuation of the conjunct matter prohibiting the generation of the antecedent. We attaine to both chiefly by four means.

The first truly by ordaining a fit manner of living and prescribing moderation in the use of the six things not naturall. Wherefore we must make choise of such air as is hot, dry and subtile; we must prescribe wine of a middle nature for his drink; let the bread be well baked; let meats be appointed which may generate good bloud, and these rather roasted than boyled. Let all fruits be forbidden, as also broths and milk-meats; let him eat such fish as are taken in stony rivers; the Patient shall observe mediocrity in feeding, but principally sobriety in drinking, for fear of crudities; after meat let him use digestive powders, or common drige powder; if his belly be not naturally loose, let it be made so by art.

Exercise.

Let the Patient use exercise before meat, so by little and little to spend this humor, and restore the native heat. Let him sleep little, because much sleep breedeth cold humors; let him avoid grief and sadness. And if he be of a weak body, let him abstain from venery, lest by another weakning by the use of venery added to his present infirmity, he fall into an incurable coldness, from whence a greater measure of crudity will arise. Otherwise, if the body be strong and lusty, by such exercises and the moderate use of venery it will be the more dryed and heated.

What to be
observed in the
use of venery.
6. Epid. sect. 5.
sen. 23.

For so that sentence of *Hippocrates* is to be understood; That venery is a cure for Phlegmatick diseases, as *Galen* in his commentaries tels us. The Physician may perform the second intention by turning his counsell to that part, from whence the spring of this Phlegmatick humor flows. For if the infirmity arise from the stomach, or from any other part, the part from whence it comes must be strengthened; if from the whole habit of the body, let attenuating, penetrating and opening medicines be prescribed. We perform the third intention by evacuating the humor impact in the part with local medicines varied according to the four times of the Tumor.

Lib. 2 ad Glauc.
cap. 3.
A rowler.

For *Galen* in the beginning and encrease prescribeth a fomentation of *Oxycratum* used with a sponge. But if so be that the *Oedema* be upon the Arm or Leg, a repelling rowler is very good, that is, such an one as is brought from below upwards. So these medicines following are very fit for the same purpose, *Rx*, *Lixivii ex cineribus sarmentorum, & caulium*, an. ζ iiii, *Tartari & Aluminis* an. ζ β , *aceti* ζ ij, mixe all together and make a decoction, wherein wet sponges and foment the place. Also you may use the following Cataplasim, *Rx*, *farine hordei* ζ iiii, *coquantur in Lixivio communi, addendo pulveris nucis cupressi, corticum granatorum, balausti*. an. ζ i, *Myrrhe, Aloes, alum.* an. ζ β , *olei Myrtill.* ζ ij, *fiat Cataplasma*. In the state and declination you must use drying and resolving medicines, as *Rx*, *Nucum cupressi, granat. sumach. balausti*, an. ζ i, *Salvia, origan. calament. Hyssopi, melissæ* an. m. i, *absinthii, plantag. caudæ equ. tappi. barb. certinod.* an. m. ss. *alum. tartar. & salis com.* an. ζ i, *coquantur cum lixivio*; foment it with a sponge, then presently apply this following Cataplasim. *Rx*, *Rad.*

Brionie

Bronia ꝛ ij, *absinth.* *plantag.* *centin.* *chamem.* *meliloti.* *peleg. an. m. ss.* *coquantur in hydromelite,* *pi-*
stentur, *trajiciantur,* *addendo pulveris ros. rub. chamem. melil. an* ꝛ i, *fiat Cataplasma.*

Lastly, you may here with good success use resolving emplaisters and ointments, first, heating or chafing the part by friction or fomentations, as well moist as dry; otherwise emplaisters will scarcely do their duty, by reason of the great coldness of the part, being not sufficient of it self to assimilate the nourishment, or to expell the superfluous and unprofitable humor. Let a fomentation be made with white Wine, in which Sage, Rosemary, Time, Lavander, Chamomile and Melilote flowers, red Roses, Orris roots, *Stachas* and such like have been boyled, with a little Vinegar added thereunto. Quench hot bricks in the same decoction, and apply them wrapped in linnen clothes to the affected part, for so a vapour will breath forth which hath an attenuating, piercing, resolving and strengthening faculty. But you may in stead of the bricks fitly apply Hogs or Oxe bladders, filled half full with the foresaid decoction, and that hot. The frictions must be made of hot linnen clothes, for so the native heat together with the bloud and spirits is recalled to the part, and fuliginous humors contained under the skin are resolved, whereby the strength of the part is in some part recovered.

What caution
to be had in
application of
Emplaisters.

CHAP. XVII.

Of the cure of flatulent and waterish Tumors.

Formerly declared that not only flatulent and waterish Tumors were comprehended under this word *Oedema*, but also such as are bred of congealed Phlegm, as *Atheromata*, *Steatomata* and *Melicerides*. Flatulent or windy Tumors are caused by vapour and wind kept in or contained sometimes under the skin, somewhiles under the membranes, as the *Periosteum* and *Pericranium*, whereupon insues cruell torment by reason of the distention of these parts which are endued with most exquisite sense. Sometimes the Entrails, as the stomach and Guts are swollen and stretched out with wind, as in a Tympany.

In what places
flatulencies
may be gather-
ed.

They in this differ from a true and ligitimate *Oedema*, that when you lay your finger upon them and take it off again, there remains no sign of the pressure thereof, because they are distent by vapour and not by humor, for the vapour being pressed returns speedily again, as you may perceive by balls or bladders filled with wind.

In what flatu-
lent tumors
differ from a
true *Oedema*.

The cause of such Tumors is the weaknes of the native heat, not being able easily to resolve and waste the Phlegm by which the windy Tumors are raised, for so the morning Sun (which in some sort resembles our native heat) cannot resolve the mists disperfed in the air; which at noon it easily resolves into pure air. Also after the same manner our weaker heat stirs up vapours from that Phlegm it could not dissolve, which vapours are the matter of inflammations, or swellings. But oft times although the native heat be sufficiently powerfull, yet because the humor lyeth deep, or is kept by the thicknes of some membrane, tendon or Ligament, the stirred up vapour cannot exhale, whereby it comes to pass, that increased by little and little it causes a Tumor.

The causes of
flatulent Tu-
mors.

The signs of such a Tumor are a certain renitency or resistance perceived by pressing it with your finger, and sometimes a noise as if you smite upon a drum, especially if much wind be contained therein, such as are often gathered together in the hollownes of the belly, and in the spaces between the larger muscles. The Tumor is neither red nor hot, but rather cold and white as in an *Oedema*. It often possesseth the joints, and especially the knees, and it is very difficult to be resolved. If such flatulency be gathered together in the Guts, it causeth the wind Colick, in which sometimes the distention is so great that death ensues by reason of the renting or tearing the coats of the Guts.

The signs of
such Tumors.

CHAP. XVIII.

Of the cure of a flatulent and waterish Tumor.

WE shall chiefly and principally cure flatulent and waterish tumors by three means. First, by the same diet which we prescribed in an *Oedema*; then by strengthening the parts appointed for concoction, as the stomach and Liver, chiefly by the temperate use of Aromatick things, as *Diacuminum*, *Diacalamentha*, *Aromaticum*, *Caryophyl-
latum*, *Aromaticum Rosatum*, and the like, to be prescribed according to good liking of the Physitian which oversees the cure; lastly, by taking away of the conjunct matter by hot, drying and attenuating medicines which they call Carminative, that so the part being rarified the humor and flatulency therein contained may be discussed and dissipated. But remedies of this nature must be varied according to the variety of the parts; for some things are fit to be applied to the stomach, others to the Guts, others to the joints, and others to the fleshy parts; for the Colick you must inject carminative glysters, let resolving *Sacculi* or Bags be applied, and cupping-glasses fastened to the Navel; if an outward part be affected

Diet
Things
strengthening
the parts.

Medicines eva-
cuating the
conjunct mat-
ter.

affected, we use fomentations, liniments, chiefly if pain torment; as also Cataplasmes and Emplaisters, as *Rx Florum chamem. melil. rorismarini, rosar. rub. an. p. j. absinthii j. hyssopi, an. m.* let them be boiled in Lye, adding a little vineger for a fomentation to be used with sponges.

Galens fomen-
tation.

Galens foment the part with Rose-vinegar and a little salt put thereto, and would have a sponge dipped therein to lye somewhat long upon the part. *Rx Olei chamem. aneth. rut. & liliorum, an. ℥β, cera albæ ℥vj. aq. vitæ ℥ij,* let them all be mixed together and make a liniment, with which anoint the part after the fomentation. *Rx Farinæ fabar. orobi, an. ℥iij, coquantur in decocto pulegii, origani, calamenth. salviæ, addita pulverem chamem. & melilot. an. m. β, fursur. farinæ fab. & orobi, an. ℥ij, coquantur cum lixivio communi, addendo terebinth. ℥iij, oleor. aneth. & rut. an. ℥ij.* make an emplaister for the foresaid use.

The emplaister of *Vigo* with Mercury, and without, is very good for the same purpose. But you must note, that such medicines must be applied to the part actually hot, and the same heat must be contained and renewed by putting about it linnen clothes, bricks, bottles and such like hot things.

Corroborating
medicines.

The Humor and flatulency which were kept shut up in the part being resolved, the part must be strengthened, lest now and then it receive or generate the like matter. That may be done by the following fomentation and cataplasme. *Rx Nucum cupressi, corticum granat. sumach. berberis, balauft. an. ℥j. caudæ equin. arnogloss. tupsii barb. absinth. salviæ, rorisim. lavendul. an. m. ss. flor. chamem. melil. rosar. anthos, an. p. j. alum. salis com. an. ℥j,* bulliant omnia in aquis partibus aquæ fabrorum & vini austeri, make bags for a fomentation, or use the decoction for the same purpose with a sponge. *Rx Farinæ fab. hordei & lupin. an. ℥ij. terebinth. com. ℥iij. pulver. radicis ireos, mastic. an. ℥β, mellis com. ℥ijβ,* of the foresaid decoction as much as shall suffice, so to make a cataplasme to the form of a poultis liquid enough, let it be applied hot to the affected part having used the fomentation before.

The signs of a
waterish tu-
mor.

The signs of a waterish tumor are the same as of a flatulent; but over and besides it shines, and at the pressing with your fingers, there is heard a noise or murmur as of a bladder half filled with water.

Why a water-
ish tumor must
be opened
with an instru-
ment.

Therefore the waterish tumor if it shal not yeeld to the forementioned resolving medicines, the way must be opened with an incision knife, after the same manner, as we mentioned in a Phlegmon. For oftentimes this kind of remedy must be necessarily used, not only by reason of the contumacie of the humor which gives no place to the resolving medicines, but also because it is shut up in its proper cist or bag, the thicknesse of which frustrates the force of the resolving medicines, neither suffers it to penetrate into the humor. As I some years agoe found by experience in a maid of 7 years old; which troubled with a *Hydrocele* or waterish rupture, to whom when I had rashly applyed to dissolve it resolving medicines of all sorts, at length I was forc't to open it with my knife; not only to evacuate the contained matter, but also that I might pluck out the bag, which unlesse it were cut up by the root, would be a mean to cause a relapse. *John Altine* Doctor of Physick called me to this businesse. *James Guilemeau* the Kings Chirurgon oversaw the cure.

A History.

CHAP. XIX.

Of an Atheroma, Steatoma, and Meliceris.

In what an
Atheroma,
Steatoma, and
Meliceris dif-
fer.

Although these tumors may be thought comprehended under one *genus* with other *Oedematous* tumors, yet they differ as thus; that is, their matter is shut up in its bladder or bag, as it were in a peculiar cell. But their difference amongst themselves is thus; the matter of the *Steatoma*, as the name signifieth, is like unto Tallow [for *Steiris* in Greek signifieth Tallow, or seam] yet it oft-times is found stuffed with other divers hard bodies, stony, bony or callous like unto the claws of an hen. For *Philoxenus* reports that he sometimes saw flies in a *Steatoma* at the opening thereof, and such other like things wholly dissenting from the common matter of Tumors. The matter contained in an *Atheroma* is like to pap, with which they feed little Children. A *Meliceris* contains matter resembling honey in colour and consistence; these tumors appear and rise without any inflammation going before them. Thus you shal know these tumors; a *Steatoma* is harder than the other two, neither yeelds it to the pressure of your finger, but when it once yeelds, it doth not speedily and easily return to its former figure, because the matter is more gross; it is of the same colour as the skin, without pain, and of a longish figure. The *Meliceris* yeelds to the touch, as being a loose and soft body, and as it is easily disposed and diffused, so it quickly returns to its former place and tumor. It differs from the *Atheroma* in figure and substance. For it is more globous and of a subtler and more shining matter, besides also it takes up a large space, and is more obsequious to the touch, and for the rest, without pain. As for the manuell operation of the Chirurgon in their cure, it seems to be of no great consequence of what sort the matter is, whether resembling tallow, honey, or pap, for there is one simple manner of operation, which is, that you pluck away the contained humor, as also the receptacle in which it is contained. Yet you must note such tumors, sometimes as it were hanging in the surface of the skin, are easily to be moved this way, and

Of Chirurgery
to be used to
these tumors.

and that way; but other some again deeper fastned firmly cohere with the adjacent bodies, and these require an exquisit hand and also industry for fear of a great flux of blood and convulsion by cutting a vein. There are many other kinds of tumors, as the *Testudo* or Mole, the *Nata*, the *Glandula*, *Nodus*, *Botium*, *Lupia*, which as in matter (for they are all of a thick, clammy and viscous Phlegmatick humor) so also in kind they agree with an *Atheroma*, *Steatoma*, and *Meliceris*. But also in these for the most part, when they are opened, you may see bodies of all sorts far different from the common matter of tumors, as stones, chalk, sand, coals, snails, straws; or awnes of corn, hey, horn, hairs, flesh both hard and spongeous; gristles, bones, whole creatures as well living as dead.

The generation of which things (by the corruption and alteration of humors) shall not make us much to admire it, if we consider, that as nature of all the seeds and elements of the whole great world, hath made man the Microcosme or little world, that he might be, as it were, the lively Image of that greater world; so in him, it being never idle in us, would have all the kinds of all motions and actions to shew themselves, as long as matter for generation is not wanting. But because there is little, or rather no mention of these tumors amongst the ancients, we will briefly shew the opinions of the later writers concerning them.

Now they say, the *Testudo* is a tumor contrary to nature, soft, diffused, or vaulted, or arched like a Tortois, sometimes it arises in the head in form of a Mole, and then it is called a Mole.

The *Nata* is a great and fleshy tumor, not in shape unlike a Melon, or rather the flesh of a mans buttocks, whence it may seem to have had the name, unless we had rather say it had it, because it more usually breeds upon the buttocks, than upon any other part of the body.

The *Glandula* takes its denomination from an Acorn, called *Glans* in Latine, the which it somewhat resembles in the compasse and form of the tumor; or else because it most commonly breeds in the Glandules, or Emunctories of mans body.

The *Nodus* or knot, is a round tumor, hard and immoveable, named from a rope tied on a knot.

Guido Cauliacensis affirms knots commonly to grow in nervous bodies; but at this time they more usually arise on the bones of such as have the French disease.

What the cause may be, that we sometimes find *infesta* in these Tumors.

What the *Testudo*, or *Talpatria* is.

What the *Nata* is.

What a *Gandula*.

What *Nodus*.

CHAP. XX.

Of the cure of *Lupia*, that is, *Wens*, or *Ganglions*.

Wen or *Ganglion* is a tumor sometimes hard, sometimes soft, yet alwaies round, using to breed in dry, hard, and nervous parts. And seeing that some of the tumors mentioned before in the former Chapter, stick immoveable to the part to which they grow, because they are contained in no cist, or bag; other some are moved up and down by the touch of your fingers, because they are contained in a bag or bladder, it commonly comes to passe that *Wens* have their bladder wherein to contain them, and therefore we think fit, the rather more freely, and particularly to treat of their cure, because they are more difficultly cured, especially where they are inveterate and of long standing.

The primitive causes of these are dull blows, fallings from high places, strains, and other such like occasions. But the antecedent and conjunct causes are the same with those of an *Atheroma*, *Meliceris* and *Steatoma*.

The description formerly set down, will furnish you with the signs by which you may know when they are present; certainly from very small beginnings they grow by little and little to a great bigness, in the space of six or seven yeers, some of them yeeld much to the touch, and almost all of them are without pain.

You may hinder such as are beginning and first growing, from encrease by somewhat a strong and frequent rubbing with your fingers. For so their bag or bladder, together with the skin wax thin, and the contained humor grows hot, is attenuated and resolved. But if so you nothing prevail, you must lie upon them with your whole hand, or a flatted peece of wood as heavy as you can, untill such time as the cist or bag be broken by your impression; Then apply and strongly bind unto it a plate of lead, rubbed over with *Quick-silver*; for I have many times found by experience, that it hath a wonderfull force to resolve and waist the subject humor. But if the *Wen* be in such a place in which you can make no strong impression, as in the face, chest, belly, & throat, let there be applied an emplaister which hath a resolving force, such as this following hath; *Re gummi ammon. bdelii, galban. an. ℥iij. liquefiant in aceto, & trajiciantur per setaceum, addendo olei liliorum & lauri, an. ℥j. aqu. vitæ parum, pulveris ireos, salis ammon. sulphur. vivi, vitrioli romani, an. ℥β.* let them be all incorporated together, and make an Emplaister according to Art. But if the tumor cannot be thus resolved, it must be opened with a knife or cautery. And after the *Eschar* is removed, and the bag waisted by *Egyptiacum*, *Mercury*, and the like, the ulcer must be cleansed, replenished with flesh, and cicatrized.

What a *Ganglion* is.

The causes.

Signes.

Their cure at the beginning.

Plates of lead rubbed with *Quick silver*. A resolving plaister. Things to waist or consume the bag.

Some-

The manner
to take away
Wens.

Sometimes Wens grow to so great a masse, that they cannot be cured by the described remedies, wherefore they must be taken away by the root, by your hand and instrument, if so be that there be no danger by reason of their greatnes, and so that they adhere not too closely to the adjacent parts, and if they be not too nigh to the greater veins and arteries; for it will be better in such a cause to let them alone. This shall be your way to cut them off, or take them away. A small incision must be made, even to the bladder, or bag, by which thrust in a probe of a fingers thickness, hollowed in the midst, round at the end, and as long as need shall require; then draw it many times about between the skin & the bag, even to the root of the Wen, that so the skin may be divided long waies, then it will be requisite to make another incision overthwart, so that they may intersect each other like a cross; then presently draw the skin from the bladder, from the corners of the Wen, towards the root, and that with your finger covered with a fine linnen cloth, or else with a Razor if need require.

But you must observe that in a Wen there are alwaies certain vessels, which are small in the beginning, but much increased in proccesse of time, according to the encrease of the Wen, whereof they are as it were the roots; wherefore if any *Hemorrhagie* or flux of blood happen, let it be stopped by binding the vessels at their heads and roots, or make a strait ligature at the roots of the Wen, with a peece of whipcord, or with a many times doubled thred, and let the ends hang forth until it fall away of its own accord. Neither will it be sufficient to have cut away all this tumor, but also it will be fit to cut away a portion of the skin, wherewith the tumor was covered, and only to leave so much as shall suffice to cover the part, then with a needle and thred draw together the lips of the incision, but in the interim let tents be put into the bottome of the ulcer untill it be perfectly cleaned, and the rest of the cure be workmanlike performed, even to the cicatrizing thereof.

A History.

The Chirurgeon *Collo* and I using this method, in the presence of Master *Dr. Violanius* the Kings Physitian, took away a Wen from *Martiall Colard*, the Major of *Burbon*; it hanged at his neck, as big as a mans head, and it weighed eight pounds; which made it so troublesome and burdnesome to him, that he was forced to carry it bound up in a towell, as in a scrip.

What Wens to
be cured by
ligature.
Which dange-
rous to cure.

Verily if these kind of tumors have a slender root and broad top, they must be straitly tied and so cut off. But it is very difficult and full of dangerous chance to take away such Wens as are seated in the neck, neer unto the Jugular veins, these under the Arm-holes, in the groins, and such as are under the ham; by reason of the deadly force of such symptoms, as may thence arise. We can only conjecture, not certainly say, what kind of matter may be contained in them. We can only know of what sort it is, when by incision it is presented to our sight. Yet in such as are very hard and do much resist the touch, there are often found matters, which in consistence may be resembled to little stones or pibles.

A History.

The matter of
a Wen is some-
times taken for
a Cancer.
Another
History.

I being on a time called to open the body of a great Lady, found in one of her breasts a body which might equal the bigness of an Hens egg, hard, and compact like a rough pible; it was held, whilst she lived, both by the Physitians and Chirurgeons, to be a *Cancer*, because this hardness was very painfull to her, when it was but gently pressed down.

How you may
know a Wen
from a Cancer.

But also some few yeers ago, I being called to the cure of a very honest woman, which was troubled with the same disease, strongly withstood the Physitians and Chirurgeons affirming it to be a *Cancer*, for the tumor had taken no deep root, the habit of the part was not changed from the native colour, the veins about it were not swollen, neither was there any other convincing sign of a *Cancer*. For this same woman had her courses at their due and usuall time, and was well liking, and had a good colour in her face and body, was free from all sort of pain, unlesse when you pressed down the part affected. Besides thence forward the tumor grew not at all; no other evill accident befel her, yea verily she lives merrily, and well both in body and mind.

CHAP. XXI.

Of a Ganglion more particularly so called.

What a Gan-
gion properly
is called is.
The causes.

Here are also certain small tumors of the kind of *Lupie* or Wens, which grow on divers parts of the body, but chiefly on the wrists of the hands, and ankles of the feet, being called by a more particular name *Ganglia*; they appear on the top of the skin, neither do they ever lie deep. The cause of them is either the imbecillity of a nerve or tendon got by wresting, extension, a blow, labour, or other such like cause. Through which occasion the alimentary juice which flowed to these parts, seeing it can neither be concocted, nor assimilated into the proper substance, is converted into an humor of the like nature cold, and gross, which in continuance of time heaping it self up by little and little about the fibers, and the very substance of the tendon, concretes into a tumor.

What *Ganglia*
may not be
cured with iron
Instruments.

It is not fit to use any iron instrument to these *Ganglia* which possess the tendons and joints, but only apply *Ammoniacum* and *Galbanum* dissolved in Vinegar and *Aqua vite*: as *Re- gum*

gummi ammon. & sagapeni in aqua vite dissolutorum, an. ℥j. coquantur super cineres calidos ad formam emplastri, sub finem adde sulphuris vivi subtiliter pulverisati ℥ss, fiat empl. ad usum. Also the Emplaister of *Vigo* with double Mercury would be good for the same purpose.

The tumor softned by these remedies, must be wrought, rubbed, or pressed, so long, untill the bladder or bag be broken under your fingers, which I have divers times done; then it will be expedient presently to apply and bind hard thereunto a plate of lead rubbed with Quick-silver, which may waite and consume the remainder of the tumor.

Sometimes there are *Ganglia* seen hanging by a small root, as it were a string; wherefore they must be tied with a string at the root, and every day twitched harder and harder, till such time as they fall off. The rest of the cure may be easily performed by the common rules of Art.

CHAP. XXII.

Of the Strumæ or Scrophulæ, that is, the Kings-evil.

The *Scrophulæ* are œdematous tumors arising in the glandulous parts, as the breasts, armholes, groins, but chiefly in the glandules of the neck. They appear either one or many, according to the quantity of that matter from whence they proceed, commonly contained in their proper cyst, or bag, as *Atheromæ*, *Steatomæ*, and *Melicrides* are.

They are made of a grosse, cold, viscid, and phlegmatick matter with some admixture of melancholy. They differ from other glandulous tumors; first in number, for most usually there appear many of them united together, springing from somewhat a deeper root than glandulous tumors doe; some of them are moveable, other some woven with the neighbouring nerves, remaining unremovable.

Gangliæ appear fewer in number, and are without pain; but *Scrophulæ* oftentimes are painful, especially when they wax hot by putrefaction; so that sometimes they degenerate into cancerous ulcers, not to be touched by instruments nor acrid medicines.

Phlegmatick, melancholick, and gluttonous persons, and such as are accustomed to feed on cold and moist nourishments, as fish and cold water, and lead a sedentarie and idle life, are subject to the *Scrophulæ*. They are cured by a most slender diet, for so the native heat by want of nourishment turned upon the material cause of such like tumors, waits it.

And they are cured by purging of the superfluous humors, and also by application of emollient resolving, and suppurating topick medicines, after this following manner. *R. Mucaginis alth. fenugr. & ficuum ping. an. ℥ij, olei liliorum, & chamem. an. ℥j, pinguedinis anseris & axungie porci ℥ss, Terebinth. Ven. ℥ss, ammoniaci, & galbani in aceto dissolutorum an. ℥j. cera nova quantum satis, fiat cerotum secundum artem ad modum diachyli magni.*

The ointment for the French disease, and the Emplaister of *Vigo* with Mercury, are excellent for this purpose, especially if we continue so long untill the Patient come to Salivation, for so nature will disburden it self of the humor, generating the *Scrophulæ*, which I have sometimes tried with happy successe. *R. Emplastri diachyl. alb. & mag. ceroti asopi descriptionis Philagrii, an. ℥ij. Terebinth. claræ ℥j. olei liliorum parum, fiat emplastrum satis molle.* But if the *Scrophulæ* cannot by this means be resolved, but as it oftentimes happens, tend to suppuration, you must use suppuratives, as *R. rad. alth. & liliorum, an. ℥iij. coquantur in aqua communi, pistentur, trajectis adde capitum alliorum sub cineribus coctorum ℥iij, olei liliorum, & ping. anseris & anat. an. ℥ss, farinae seminis lini quantum satis, formetur cataplasma.*

Here we must admonish the Chirurgeon, that he open not the *Scrophulæ* before that all the contained humor be fully and perfectly turned into pus or matter; otherwise the residue of the humor will remain crude, and will scarce in a long time be brought to maturation; which precept must be principally observed in the *Scrophulæ*, and also sometimes in other abscesses, which come to supuration. For we must not as soon as any portion of the contained humors appears converted into pus, procure and hasten the apercion. For that portion of the suppurated humor, causes the rest sooner to turn into pus, which you may observe in inanimate bodies. For fruits which begin to perish and rot, unless we presently cut away the putrefying part, the residue quickly becomes rotten; there is also another reason; The native heat is the efficient cause of supuration; it therefore (the sore being opened) diminished and weakened by reason of the dissipation of the spirits, evacuated together with the humor, will cause the remaining portion of the humor not to suppurate, or that very hardly, and with much difficulty. Yet if the tumified part be subject, by its own nature, to corruption and putrefaction, as the fundament; if the contained matter be malign, or critical, it will be far better to hasten the apercion.

There is also another way of curing the *Scrophulæ*, which is performed by the hand. For such as are in the neck; and have no deep roots, by making incision through the skin, are pulled and cut away from these parts with which they were intangled. But in the performance of this work, we take speciall care, that we doe not violate or hurt with our instrument, the jugular veins, the sleepey arteries, or recurrent nerves. If at any time there be dan-

ger of any great efflux of blood, after they are plucked from the skin, they must be tied at their roots, by thrusting through a needle and thred, and then binding the thred strait on both sides, that so bound they fall off by themselves by little and little without any danger. The remainder of the cure may be performed according to the common rules of Art.

CHAP. XXIII.

Of the Feaver which happens upon an œdematous Tumor.

How an intermitting Quotidian happens upon œdematous tumors. The cause of a Quotidian feaver.

Having shewed all the differences of œdematous tumors, it remains that we briefly treat of the Symptomatical feaver, which is sometimes seen to happen upon them. This therefore retaining the motion of the humor by which it is made, is commonly of their kind, which they name Intermitting Quotidians. Now the fit of a Quotidian comes every day, and in that repetition continues the space of eighteen hours; the residue of the day it hath manifest intermission.

The primitive causes of this feaver are, the coldnesse and humidity of the air encompassing us, the long use of cold meats and drinks, and of all such things as are easily corrupted, as Summer fruits, crude fishes, and lastly, the omission of our accustomed exercise.

The antecedent causes are a great repletion of tumors, and these especially phlegmatick. The conjunct cause, is phlegm putrefying in the habit of the body, and first region thereof without the greater veins.

The Signs.

The signs of this feaver are drawn from three things; as first naturall; for this Feaver or Ague chiefly seizes upon these which are of a cold and moist temper, as Old-men, Women, Children, Eunuches, because they have abundance of phlegm; and it invades Old-men by its own nature, because their native heat being weak, they cannot convert their meats, then taken in a small quantity, into laudable blood, and the substance of the parts. But it takes children by accident, not of its self, and the own nature, for children are hot and moist; but by reason of their voracity, or greediness, and their violent, inordinate, and continuall motion after their plentiful feeding, they heap up a great quantity of crude humors fit matter for this feaver; whereby it comes to passe, that fat children are chiefly troubled with this kind of feaver, because they have the passages of their bodies strait and stopped, or because they are subject to Worms, they are troubled with pain, by corruption of their meat; whence ariseth a hot distemper by putrefaction, and the elevation of putrid vapors, by which the heart being molested, is easily taken by this kind of feaver.

How children come to be subject to Quotidian feavers.

From things not naturall, the signs of this feaver are thus drawn. It chiefly takes one in Winter, and the Spring, in a cold and moist Region, in a sedentary and idle life, by the use of meats, not only cold and moist, but also hot and dry, if they be devoured in such plenty, that they overwhelm the native heat.

How phlegmatick humors happen to be generated by hot and dry meats.

For thus wine, although it be by faculty and nature, hot, and dry, yet taken too immoderately, it accumulates phlegmatick humors, and causes cold diseases. Therefore drunkenness, gluttony, crudity, bathes and exercises presently after meat, being they draw the meats as yet crude into the body and veins; and to conclude, all things causing much phlegm in us, may beget a Quotidian feaver. But by things contrary to nature, because this feaver usually follows cold diseases, the Center, Circumference, and Habit of the body being refrigerated.

The symptoms of Quotidians.

The symptoms of this feaver are, the pain of the mouth of the stomach, because that phlegm is commonly heaped up in this place, whence follows a vomiting, or casting up of phlegm; the face looks pale, and the mouth is moist, without any thirst, oftentimes in the fit it self; because the stomach flowing with phlegm, the watery and thinner portion thereof continually flows up into the mouth and tongue, by the contiunity of the inner coat of the ventricle common to the gullet and mouth.

The manner of the pulse and hearin a Quotidian.

It takes one with coldness of the extreme parts, a small and deep pulse, which notwithstanding in the vigour of the fit, becomes more strong, great, full, and quick. Just after the same manner, as the heat of this feaver at the first touch appears mild, gentle, moist and vaporous; but at the length it is felt more acrid, no otherwise than fire kindled in green wood, which is small, weak, and smoakie at the first; but at the length when the moisture being overcome, doth no more hinder its action, it burns and flames freely.

Critical sweats. The urin.

The Patients are freed from their fits with small sweats, which at the first fits break forth very sparingly, but more plentifully when the *Crisis* is at hand; the urin at the first is pale and thick, and sometimes thin, that is, when there is obstruction. But when the matter is concoct, as in the state, it is red; if at the beginning of the fit they cast up any quantity of phlegm by vomit, and that fit be terminated in a plentiful sweat, it shews the feaver will not long last; for it argues the strength of nature, the yeelding and tenuitie of the matter flying up, and the excretion of the conjunct cause of the feaver.

Why Quotidians are oftentimes long. Into what diseases a Quotidian usually changes.

A Quotidian feaver is commonly long, because the phlegmatick humor being cold, and moist by nature, is heavy and unapt for motion: neither is it without fear of a greater disease, because oftentimes it changes into a burning, or quartain feaver, especially if it be bred

of salt Phlegme, for saltneis hath affinity with bitterneis, wherefore by adustion it easily degenerates into it, so that, it need not seem very strange, if salt phlegm by adustion turn into choler, or melancholy. Those who recover of a Quotidian feaver, have their digestive faculty very weak; wherefore they must not be nourished with store of meats, nor with such as are hard to digest. In a Quotidian the whole body is filled with crude humors, wherefore by it comes to passe that this Feaver oft-times lasts sixty daies. But have a care, you be not deceived, and take a double tertian for a Quotidian, because it takes the Patient every day as a Quotidian doth. Verily it will be very easie to distinguish these Feavers by the kind of the humor, and the propriety of the symptomes and accidents; beside, Quotidians commonly take one in the evening, or the midst of the night, as then when our bodies are refrigerated by the coldness of the air caused by the absence of the Sun. Wherefore then the cold humors are moved in us, which were bridled a little before by the presence and heat of the Sun. But on the contrary, double tertians take one about noon. The shortness and gentleness of the fit, the plentiful sweat breaking forth, the matter being concocted, causes us to think the Quotidian short and salutary.

The cure is performed by two means; to wit, Diet, and Pharmacy. Let the Diet be slender and attenuating, let the patient breath in a cleer air moderately hot and dry; let his meats be bread well baked, cock or chicken broths in which have been boiled the roots of Parsly, Sorrell and the like.

Neither at sometimes will the use of hot meats, as those which are spiced and salted, be unprofitable, especially to such as have their stomach and liver much cooled. Let him eat Chickens, Mutton, Partridge and small birds, river fishes and such as live in stony waters fryed or boiled, rear eggs and such like. These fruits are also good for him, Raisons, stewed Prunes, Almonds and Dates. Let his drink be small white wine mixed with boiled water. Moderate exercises will be good, as also frictions of the whole body: sleep taken at a fitting time, and proportioned to waking, so that the time of sleep fall not upon the time of the fit; for then it hurts very much; for calling the heat to the inner parts, it doubles the raging of the feaverish heat inwardly in the bowels.

For the passions of the mind, the patient must be merry, and comforted with a hope shortly to recover his health. It seems not amisse to some, at the coming of the fit to put the feet and legs into hot water, in which Chamomill, Dill, Melilot, Marjerom, Sage, and Rosemary have been boiled.

The medicines shall be such syrups as are called digestive and aperitive, as syrup of Wormwood, Mints, of the five opening roots, *Oxymel* with a decoction of Chamomill, Calamint, Melilot, Dill, and the like, or with common decoctions. The Purgatives shall be *Diaphanicon*, *Electuarium Diacarthami*, *Hiera picra*, Agarick, Turbith, of which you shall make potions with the water of Mints, Balm, Hyssop, Sage, Fennell, Endive or the like, *Pillule aureae* are also good. These purgatives shall sometimes be given in form of a bole with sugar, as the Physitian being present shall think most fit and agreeable to the nature of the Patient.

About the state of the disease, you must have a care of the stomach and principally of the mouth thereof, as being the chief seat of phlegm; wherefore it will be good to anoint it every other day with oil of Chamomill mixed with a little white wine, as also to unlade it by taking a vomit of the juice of Radish, and much *Oxymel*, or with the decoction of the seeds and roots of *Asarum* and Chamomill; and syrup of vinegar will be very good, especially at the beginning of the fit, when nature and the humors begin to move; for an inveterate Quotidian, though you can cure it by no other remedy, nothing is thought to conduce so much as one dram of old Treacle taken with sugar in form of a bole, or to drink it dissolved in *Aqua vite*.

CHAP. XXIV.

Of a Scirrhus, or an hard tumor proceeding of Melancholy.

Having shewed the nature of tumors caused by blood, choler and phlegm, it remains we speak of these, which are bred of a melancholick humor; of these there are said to be four differences. The first is of a true and legitimate *Scirrhus*, that is, of an hard tumor endued with little sense, and so commonly without pain, generated of a naturall melancholick humor. The second is; of an illegitimate *Scirrhus*, that is of an hard tumor insensible; and without pain, of a Melancholick humor concrete by too much resolving and refrigerating. The third is of a cancrus *Scirrhus* bred by the corruption and adustion of the Melancholick humor. The fourth of a phlegmonous, *Erysipelous* or *Oedematous Scirrhus*, caused by Melancholy mixed with some other humor. The cause of all these kinds of Tumors is a grosse, tough and tenacious humor concrete in any part. But the generation of such an humor in the body happens either of an ill and irregular diet, or of the unnaturall affects

Medicines.

Care must be had of the stomach Vomits.

The use of Treacle in an inveterate quotidian.

What a true and legitimate Scirrhus is. What an illegitimate Scirrhus is.

The Signs.

of the liver or spleen, as obstruction; or by suppression of the *Hæmorrhoids* or Courses. The signs are hardness, renitency, a blackish colour, and a dilation of the veins of the affected part with blackishness, by reason of the abundance of the gross humor. The illegitimate or bastard *Scirrhus* which is wholly without pain and sense, and also the cancerous admit no cure, and the true legitimate scarce yeeld to any. Those which are brought to suppuration, easily turn into Cancers and fistulaes; these tumors though in the beginning they appear little, yet in process of time they grow to a great bigness.

Prognostick.

CHAP. XXV.

Of the cure of a Scirrhus.

Diet.

He Cure of a *Scirrhus* chiefly consists of three heads. First, The Physician shall prescribe a convenient diet, that is sober and moderate in feeding, tending to humidity, and indifferent heat; for his manner of life, let it be quiet and free from all perturbation of anger, grief and sadness, as also abhorring the use of venery. The second is placed in the evacuation of the antecedent matter, as by Phlebotomy, if need require, and by purging, by procuring the *Hæmorrhoids* in men, and the courses in women; let purgations be prescribed of *Diacatholicon*, *Hiera*, *diarsenna*, *polypody*, *Epythymum* according to the mind of the learned Physician. The third consists in the convenient use of Topick medicines, that is, emollient at the beginning, and then presently resolving, or rather such as are mixed both of resolving and emollient faculties, as *Galen* teaches; for by the use of only emollient things there is danger of putrefaction and a *Cancer*, and only of resolving there is fear of concretion, the subtiler part being resolved, and the grosser subsiding.

Lib. 2. ad Glauconem.

Emollients.

The emollient shall be thus: *R Rad. alb. lib. s. rad. liliorum ℥iij. coquantur in aqua com. pistentur, trajiciantur per setaceum, addendo olei chamæ. & lilior. an. ℥ij. aspi humide ℥ss. emplastri diachyl. alb. cum oleo liliorum dissoluti ℥iij, ceræ albæ quantum sit satis, fiat cerotum.* Or *R gummi ammoniaci, galb. bdellii, styracis liquidæ in aceto dissolutorum, an. ℥j, diachyl. mag. ℥jss, olei liliorum, & unguis anseris, an. ℥j. ceroti aspi. descriptione Philagr. ℥ij. liquecant omnia simul, ceræ quantum sit satis, ut inde fiat cerotum satis molle.* When you have sufficiently used emollient things, fume the tumor with strong Vinegar and *Aqua vitæ* poured upon a piece of a Millstone, flint or brick heated very hot; for the so mollified humor will be rarified, attenuated and resolved; then some while after renew your emollients, and then again apply your resolvers to wast that which remains, which could not be performed together and at once; for thus *Galen* healed a *Scirrhus* in *Cercilus* his son. Goats dung is very good to discusse *Scirrhus* tumors; but the Emplaster of *Vigo* with a double quantity of Mercury is effectual above the rest, as that which mollifies, resolves and wasts all tumors of this kind.

the Empl. of
Vigo with
Mercury.

CHAP. XXVI.

Of a Cancer already generated.

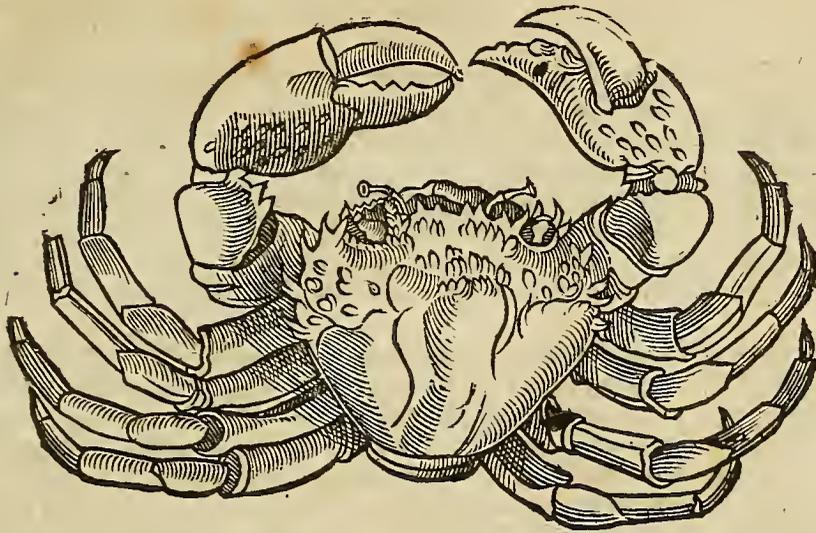

What a Cancer is.

Cancer is an hard tumor rough and unequal, round, immoveable, of an ash or livid colour, horrid by reason of the veins on every side, swollen with black blood, and spread abroad to the similitude of the stretched out legs and claws of a Crab. It is a tumor hard to be known at the first, as that which scarce equals the bigness of a Chick, or *Cicer*, after a little time it will come to the greatnesse of a Hasell nut, unless peradventure provoked by somewhat too acrid medicins it sodainly encrease being grown bigger, according to the measure of the encrease it torments the patient with pricking pain, with acrid heat, the grosse blood residing in the veins growing hot, and inferring a sense like the pricking of needles, from which notwithstanding the Patient hath oft-times some rest. But because this kind of tumor by the veins extended and spread about it like claws and feet, being of a livid and ash colour, associated with a roughness of the skin and tenacity of the humor, represents, as it were, the toothed claws of the Crab, therefore I thought it not amisse here to insert the Figure of the Crab, that so the reason both of the name and thing might be more perspicuous.

The nature of
the pain.
The reason of
the name.

The figure of the Crab, called Cancer in Latin.

CHAP. XXVII.

Of the causes, kinds, and prognosticks of a Cancer.

Here we acknowledge two causes of a *Cancer*, the antecedent, and conjunct. The antecedent cause depends upon the default of irregular diet, generating and heaping up grosse and feculent blood; by the morbifick affection of the Liver disposed to the generation of that blood; by the infirmity or weakness of the spleen in attracting and purging the blood; by the suppression of the Courses or Hemorrhoids, or any such accustomed evacuation. The conjunct cause is that gross and melancholick humor sticking and shut in the affected part as in a strait. That melancholick blood which is more mild, and less malign, only increased by a degree of more fervid heat, breeds a not ulcerated *Cancer*, but the more malign and acrid causes, an ulcerated. For so the humor which generated Carbuncles, when it hath acquired great heat, acrimony, and malignity, corrodes, and ulcerates the part upon which it alights. A *Cancer* is made more fierce and raging by meats inflaming the blood, by perturbations of the mind, anger, heat, and medicines too acrid, oily, and emplastick, unfitly applied, both for time and place.

Amongst the sorts or kinds of *Cancers*, there be two chiefly eminent, that is, the ulcerated or manifest *Cancer*, and the not ulcerated or occult. But of *Cancers* some possess the internall parts, as the Guts, Womb, Fundament; others the externall, as the Breasts; also there is a recent, or late bred *Cancer*, and also an inveterate one. There is one small, another great, one raging and malign, another more mild. Every *Cancer* is held almost incurable, or very difficult to be cured, for it is a disease altogether malign, to wit, a particular Leprosie. Therefore saith *Aetius*, a *Cancer* is not easily staid untill it hath eaten even to the innermost of the part which it possesses. It invades women more frequently than men, and those parts which are lax, rare, fungous, and glandulous, and therefore opportune to receive a defluxion of a grosse humor; such are the breasts and all the emunctories of the noble parts. When it possesses the breasts, it often causes inflammation to the armpits, and sends the swelling ever to the glandules thereof; whereupon the Patients do complain that a pricking pain, even pierces to their hearts. But this same pain also runs to the clavicles, and even to the inner side of the shoulder-blades and shoulders. When it is increased, and covers the noble parts, it admits no cure but by the hand; but in decayed bodies, whose strength fail, especially if the *Cancers* be inveterate, we must not attempt the cure, neither with instrument, nor with fire, neither by too acrid medicines, as potentiall cauteries: but we must only seek to keep them from growing more violent, and from spreading further, by gentle medicines, and a palliative cure. For thus many troubled with a *Cancer*, have attained even to old age. Therefore *Hippocrates* admonishes us, that it is better not to cure occult, or hidden *Cancers*; for the Patients cured (saith he) do quickly die, but such as are not cured live longer.

The causes of a *Cancer*.

The causes of a not ulcerated *Cancer*.

The sorts and differences of *Cancers*.

Aetius lib. 6.
The parts most subject to *Cancers*.

What *Cancers* one must not undertake truly to cure.

CHAP. XXVIII.

Of the Cure of a Cancer beginning, and not yet ulcerated.

Cancer beginning is oft hindred from encreasing, before it fasten its roots, but when it hath once encreased, it admits no cure but by iron, as that which contemns, by reason of the malignity & contumacy, the force of all medicines. Galen affirms, he cured a Cancer not ulcerated.

Lib. 2. ad Glau.

Now that cure is performed by medicines, purging melancholy, by Phlebotomy, when the strength and age of the Patient may well endure it, by shunning all things which may breed ill and fœulent blood. The distemper of the Liver must first be corrected, the Spleen ned, as also the part affected; in men the Hæmorrhoides, in women their Courses must be procured.

Diet.

Therefore thick and muddy wines, vinegar, brown bread, cold herbs, old cheese, old and salted flesh, beef, venison, goat, hare, garlick, onions and mustard; and lastly all acrid, acid and other salt things, which may by any means incrassate the blood, and inflame the humors, must be eschewed. A cooling and humecting diet must be prescribed; fasting eschewed, as also watchings, immoderate labours, sorrow, cares, and mournings; let him use ptisans; and in his broths boil Mallows, Spinace, Lettuce, Sorrell, Purslain, Succory, Hops, Violets, Borrage and the four cold seeds. But let him feed on Mutton, Veal, Kid, Capon, Pullet, young Hares, Partridges, Fishes of stony rivers, rear Eggs; and use white wine but moderately for his drink.

How to handle the cancerous part.
Antidotes.
Asses milk.

The part affected with the Cancer must be gently handled, and not overburdened by over hard or heavy things, or by too solid or fat Emplaisters; on the contrary gentle and mitigating medicines must be used; applying also at certain times such things as resist venome or poyson, as Treacle and Mithridate. Asses milk is exceeding fit to asswage the acrimony of the cancerous humor. Therefore it must not only be taken inwardly, but also applied outwardly to the cancerous ulcer, making thereof a fomentation.

CHAP. XXIX.

Of the cure of an ulcerated Cancer.

The Signs.

AN Ulcerated Cancer hath many signs common with that which is not ulcerated, as the roundness of the tumor, the inequality, roughness, and pain; to the judgment of the eye, the tumor seems soft, but it is hard to the touch; the Ulcer is filthy, with lips, thick, swollen, hard, knotty, turned out, and standing up, having a horrid aspect, and casting forth ichorous, filthy, and carion-like filth, sometimes black, sometimes mixed with rotten filth, and otherwhiles with much blood. This kind of ulcer is malign, rebellious, and untractable, as that which contemns mild remedies, and becomes more fierce, by acrid and strong; the pain, fever, and all the symptoms being increased, from whence the powers are dejected, the wasting and consumption of the body follows and lastly death. Yet if it be small, and in a part which may suffer amputation, the body being first purged, and blood drawn, the strength of the Patient not disswading, it will be convenient to use the hand, and to take hold of, and cut away whatsoever is corrupt, even to the quick, that no fear of contagion may remain, or be left behind. The amputation finished, the blood must not be presently stopped, but permitted to flow out in some measure, yea verily pressed forth all about it, that so the veins swollen with black and melancholy blood may be disburdened. When you have taken a sufficient quantity of blood, the place must be seared with an actual cautery. For that will strengthen the part affected, draw forth the venenate quality, and also stay the defluxion. Then must you apply mitigating medicines, and procure the falling away of the Eschar. To conclude, that which remains, must be performed according to the cure of other ulcers. Now we know and understand that all the Cancer is cut away, and all the malignity thereof extinct, when the ulcer casts forth laudable matter, when that good flesh begins to grow by little and little, like to the grains of a Pomegranat, the pricking pain, and all the symptoms being asswaged. Yet the cure of an ulcerated Cancer which shall possess the lips may be more happily and mildly performed, no caustick medicine being applied after section, so also that scarce any deformity will be left, when it is cicatrized. Which new and never formerly tried, or written of way, as far as I know, I found and performed in a man of fifty years old. Doctor John Altine, a most learned Physician being called to Counsell, James Guillemeau, and Master Eustachius the Kings Chirurgeons, and John Le Jeune the Duke of Guise his most worthy Chirurgeon being present.

How & where a Cancer may be cut away.
What to be observed in cutting away a Cancer.
The benefit of applying a cautery after amputation of the Cancer.

Signs that a Cancer is well taken away.

The way is this; The Cancer must be thrust through the lips on both sides, above and below

below with a needle and thred, that so you may rule and govern the *Cancer* with your left hand, by the benefit of the thred (lest any portion thereof should scape the instrument in cutting) and then with your Siziers in the right hand, you may cut it off all at once; yet it must be so done, that some substance of the inner part of the lip, which is next to the teeth may remain, (if so be that the *Cancer* be not grown quite through) which may serve as it were for a foundation to generate flesh to fill up the hollownes again. Then when it hath bled sufficiently, the sides and brinks of the wound must be scarified on the right and left sides, within, and without, with somewhat a deep scarification, that so (when we would draw together the sides and lips of the wound, by that manner of stitching, which is used in an hare lip) we may have the flesh more pliant and tractable to the needle and thred. The residue of the cure must be performed just after the same manner as we use in hare lips; of which we shall treat hereafter.

A new and observable way of taking away a *Cancer* from the lip.

CHAP. XXX.

Of the Topicke medicines to be applied to an ulcerated, and not ulcerated *Cancer*.

WE at the beginning use repercussive medicines, such as are the juices of Nightshade, Plantain, Henbane, Lettuce, Sorrell, Houfeleek; Water Lentill or Ducks meat, Knotgrasse, Pomegranates, and the like. Also *oleum rosarum omphacinum*, the powders of Sumach, Berberies, Litharge, Ceruse, Burnt-lead, Tutia, Quicksilver, and the like. Of which you may compose Fomentations, Liniments, Ointments, Cataplasmes, Emplaisters. *Emplastrum Diacalcitheos* dissolved with juice of Nightshade, and oil of Roses is very fit for not ulcerated *Cancers*. *Pompholix*, or Tutia, washed in juice of Nightshade, or Plantain, is very good for ulcerated *Cancers*. Besides this following medicine is very commendable.

Repelling medicines.

Rx Lytharg. & cerus. an. ʒj, terantur in mortario plumb. cum oleo rosar. donec reducantur ad consistentiam linimenti vel unguenti; and there may be use of a resolving and repercussive ointment, as *Rx plumbi usti loti, pomphol. thuris, an. ʒijʒ, absinth. pontic. ʒʒ, olei rosarum ʒiij, ceræ ʒvj, succi solani, quantum sufficit ad unguenti crassitudinem.* They very much commend *Theodorickes Emplaister* to asswage the pain of ulcerated *Cancers*.

Rx olei ros. ceræ alb. an. ʒijʒ, succi granat. & solani, an. ʒij, cerusæ lotæ ʒj, plumbi usti, loti, & tuthiæ prepar. an. ʒʒ, thuris, mastich. an. ʒij, fiat empl. molle. This following ointment I have often used with good successe,

Theodorickes Emplaister.

Rx Theriac. veter. ʒj, succi cancerorum ʒʒ, succi lactucæ & olei rosar. an. ʒijʒ, vitel. ovorum sub cinerib. coct. ij, camphor. ʒʒ. pistentur omnia in mortario plumb. & fiat unguentum.

Rx Spum. argent. axungia porci recentis, ceræ alb. an. ʒʒʒ, olei boni ʒvij, vitel. ovorum assat. iijj, fiat unguent. servetur usui. And when you will use it, mix it with a little ointment of Roses. I have also mitigated great pain by applying Leaches to an un ulcerated *Cancer*, in that part where the torment was most vehement, by disburdening the part of some portion of the malign humor; which same thing I have done by application of yong Whelps, or Kitlings, or Pidgeons, or Chickens cut long waies, and presently applied to the ulcer, and now and then changed as soon as their heat seems dissolved; and others applied for the naturall heat in an anodyne or mitigating medicine. *John Baptista Theodosius* in his Epistles, writes, that a cataplasme of the herb *Erysimum* or Cadlock, being beaten, is very good to be applied to a *Cancer* not ulcerated; but if the *Cancer* be ulcerated, he boils this same herb in *Hydromel*, and so by injections and lotions cleanses the ulcer, and mitigates the pain. If the *Cancer* affect the womb, the patient feels the pricking of the pain in the groins above the *pecten*, and in the Kidneyes, and is often troubled with a difficulty of making water; but when it is ulcerated it poures forth filth or matter exceeding stinking and carion-like, and that in great plenty; the filthy vapour of which carryed up to the heart and brain causes often fwounding. Now to mitigate the pains of such like places, the following medicines are of good use.

Leaches.

The application of Whelps, Chickens, &c.

Epist. 21.
The estate of *Erysimum*.
The signs of the *Cancer* in the womb.

Rx Mucag. semin. lini; sænigr. extract. in aqua rosar. & plantaginis quod satis est; Of this being warm make a fomentation.

Rx Rad. Athæ ʒʒ. coquatur in hydromelite, pistetur & trājiciatur, addendo olei rosar. parum, fiat Cataplasma. Also you shall make divers pessaries according to the different kinds of pain; also make injections of the juice of Plantain, Knotgrasse, Lettuce, Purslain mixed together, and agitated or laboured in a leaden mortar with a little oil of Roses; for this kind of medicine is commended by *Galen* in every kind of ulcerated *Cancers*. Also this following water is very profitable, and often approved by me. *Rx Stercoris bubuli ʒiij, herbæ Roberti, plantag. sempervivi, hysciami, portulac. lactuc. endiv. an. m. j. canros fluviatiles, num. xij.* let them be all beaten together and distilled in a leaden Alembick, keep the liquor for use and with it make often injection into the part; or if the site of the part will permit, let the cancerous ulcers be washed therewith, and pledgets of lint steeped therein, be applyed and renewed

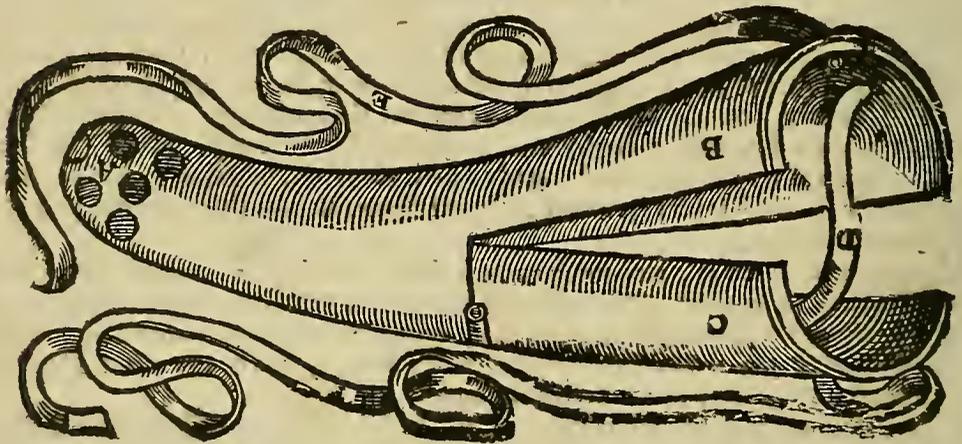

Lib. 9. Simplic.

Lib. 4. de comp.
med. secundum
gen.

ever and anon; for so the acrimony and force of the inflammation is retunded, and the pain asswaged. *Galen* beats into powder river Crabs burnt; the powder mixed with ointment of *Roses* is most profitably applied upon lint to cancerous ulcers.

It will be very convenient to put into the neck of the womb the following instrument made of Gold or Silver, whereby the cancerous filth may have free and safe passage forth, and the filthy and putredinous vapors may more easily breath forth. Therefore let it be hollow quite through, some five or six fingers long, and about the bigness of ones thumb, at the upper end, perforated with many holes whereby the filth may have passage forth. Let the outer or lower end be some two fingers thick in the circumference, make it with a neat spring, that may hold that end open more, or less, according to the Physitians mind; let there be two strings or laces put unto it, by which being tyed before and behind to the rowler, with which the woman shall girt her loins, the Device may be kept from falling, as you may see in the following figure.

A Vent made like a Pessary for the womb affected
with a cancerous ulcer.

- A. Shews the upper end perforated with five or six holes.
B. The lower end.
C. That part of the end which is opened by the spring, which is marked with the Letter D.
EE. The strings or laces.

Lib. 6. simp.
Plates of Lead.

A History.

Neither is that remedy for not ulcerated *Cancers* to be contemned, which consists of a plate of lead besmeared with *Quick-silver*; for *Galen* himself testifies that lead is a good medicine for malign and inveterate ulcers. But *Guido Cauliacensis* is a witness of ancient credit and learning, that such plates of lead rubbed over with *Quick-silver*, to such malign ulcers as contemn the force of other medicines, are as it were *Antidotes*, to waite and overcome their malignity and evill nature. This kind of remedy, when it was prescribed by that most excellent Physitian *Hollerius*, who commanded me to apply it to the Lady of *Montigni* Maid of Honour to the Queen mother, troubled with a *Cancer* in her left brest, which equalled the bigness of a *Wallnut*, did not truly thoroughly heal it, yet notwithstanding kept it from further growth. Wherefore at the length growing weary of it, when she had committed herself to a certain Physitian boldly promising her quick help, she tryed with losse of her life, how dangerous, and disadvantageous the cure of a *Cancer* was, which is undertaken according to the manner of healing other ulcers; for this Physitian, when he had cast away this our medicine, and had begun the cure with mollifying, heating and attractive things, the pain, inflammation and all the other symptomes encreasing the tumor grew to that bignesse, that being the humor drawn thither could not be contained in the part it self, it stretched the brest forth so much, that it broke it in the middle, just as a *Pomgranat* cleaves when it comes to its full maturity; whereupon an immoderate flux of blood following, for staying whereof he was forc't to strew caustick powders thereon; but by this means the inflammation and pain becoming more raging, and swoundings coming upon her, she poor Soul in stead of her promised health, yeilded up her ghost in the Physitians bosome.

CHAP. XXXI.

Of the Feaver which happeneth in Scirrhus Tumors.

Such a Feaver is a Quartain, or certainly coming near unto the nature of a Quartain, by reason of the nature of the Melancholick humor of which it is bred. For this shut up in a certain feat in which it makes the tumor, by communication of putrid vapours heats the heart above measure, & enflames the humors contained therein, whence arises a Feaver. Now therefore a quartain is a Feaver coming every fourth day, and having two dayes intermission.

The primitive causes thereof are these things which increase Melancholick humors in the body, such as the long eating of pulse, of course and burnt bread, of salt flesh and fish, of gross meats, as Beef, Goat, Venison, old Hares, old Cheese, Cabbage, thick and muddy wines and other such things of the same kind.

The antecedent causes are a heaped up plenty of Melancholick humors abounding over all the body. But the conjunct causes are Melancholick humors putrefying without the greater vessels, in the small veins and habit of the body.

We may gather the signs of a Quartain feaver from things which they call naturall, not naturall, and against nature; from things naturall, for a cold and dry temper, old age, cold and fat men, having their veins small, and lying hid, their spleen swollen and weak, are usually troubled with quartain Feavers.

Of things not naturall; this Feaver, or Ague is frequent in Autumne, not only because, for that it is cold and dry, it is fit to heap up Melancholick humors; but chiefly by reason that the humors by the heat of the preceding Summer are easily converted into adust Melancholy, whence far worse and more dangerous quartains arise, than of the simple Melancholick humor; to conclude, through any cold or dry season in a region cold and dry, men that have the like Temper easily fall into quartains; if to these painfull kind of life full of danger and sorrow doth accrew.

Of things contrary to nature; because the fits take one with painfull shaking, inferring as it were the sense of breaking or shaking the bones; further it taketh one every fourth day with an itching over the whole body, and oft-times with a thin skurfe and pustules, especially on the legs; the pulse at the beginning is little, slow, and deep, and the urine also is then white and waterish, inclining to somewhat a dark colour.

In the declination when the matter is concocted the urine becomes black, not occasioned by any malign Symptome or preternaturall excess of heat, (for so it should be deadly) but by excretion of the conjunct matter. The fit of the Quartain continues 24 houres, but the intermission is 48 houres. It often takes its originall from an obstruction, pain, and Scirrhus of the Spleen, and of the suppression of the courses and Hæmorrhoides.

Quartains taken in the Summer are for the most part short, but in the Autumn long, especially such as continue till Winter. Those which come by succession of any disease of the Liver, Spleen, or any other precedent disease are worse than such as are bred of themselves, and commonly end in a Dropsie. But those which happen without the fault of any bowels, and to such a patient, as will be governed by the Physician in his Diet, infer no greater harm, but free him from more grievous and long diseases, as Melancholy, the Falling sickness, Convulsions, Madnes, because the Melancholy humor, the author of such diseases is expelled every fourth day by the force of the fit of the Quartain.

A Quartain Feaver, if there be no error committed, commonly exceeds not a year, for otherwise some Quartains have been found to last to the twelfth year according to the opinion of Avicen: the Quartain beginning in Autumn is oft-times ended in the following spring; the Quartain which is caused by adust blood, or choler, or Salt flegm, is more easily and sooner cured, than that which proceeds from an adust Melancholy humor; because the Melancholy humor, terrestriall of its own nature, and harder to be dissolved than any other humor, is again made by adustion (the subtiler parts being dissolved and the grosser subsiding) more stubborn, gross, malign, and acrid. The cure is wholly absolved by two means, that is, by Diet and medicines. The diet ought to be prescribed contrary to the cause of the Feaver in the use of the six things not naturall, as much as lyes in our power.

Wherefore the Patient shall eschew Swines flesh, flatulent, viscid and glutinous meats, fenny fowls, salt meats and Venison, and all things of hard digestion. The use of white wine indifferent hot and thin, is convenient to attenuate and incide the gross humor, and to move urine and sweat; yea verily at the beginning of the fit a draught of such wine will cause vomiting, which is a thing of so great moment, that by this one remedy many have been cured. Yet if we may take occasion and opportunity to provoke vomit there is no time thought fitter for that purpose than presently after meat; for then it is the sooner provoked, the fibers of the stomach being humected and relaxed, and the stomach is sooner turned to vomiting, whereupon follows a more plentiful, happy & easie evacuation of the Phlegmaticke and Cholerick humor, and less troublesome to nature: and of all the cru-

Why a quartain happens upon scirrhus tumors.

Why they are frequent in Autumne.

Prognostick.

From what diseases a quartain frees one.

Diet.

How much vomiting prevails to cure a quartain.

dicities with which the mouth of the ventricle abounds in a Quartane, by reason of the more copious afflux of the Melancholick humor, which by his qualities cold and dry, disturbs all the actions and naturall faculties. Moreover exercises and frictions are good before meat; such passions of the mind as are contrary to the cause from which this Feaver takes his originall, are fit to be cherished by the patient; as Laughter, Jestings, Musick, and all such like things full of pleasure and mirth. At the beginning the patient must be gently handled and dealt withall, and we must abstain from all very strong medicines untill such time, as the disease hath been of some continuance. For this humor, contumacious at the beginning when as yet nature hath attempted nothing, is again made more stubborn, terrestriall and dry, by the almost fiery heat of acrid medicines. If the body abound with blood, some part thereof must be taken away by opening the Median or Basilik vein of the left arm, with this caution, that if it appear more gros and black, we suffer it to flow more plentifully; if more thin, and tintured with a laudable red colour that we presently stay it. The matter of this feaver must be ripened, concocted and diminished with the Syrups of *Ephithimum*, of *Scolopendrium*, of Mayden hair, Agrimony, with the waters of Hops, Bugloss, Borage and the like. I sincerely protest, next unto God, I have cured very many quartains by giving a portion of a little Treakle dissolved in about some two ounces of *Aqua vita*, also sometimes by two or three grains of Musk dissolved in Muscadine, given at the beginning of a particular fit towards the generall declination of the disease, after generall purgations the humor and body being prepared, and the powers strong; And certainly an inveterate Quartain can scarce ever bee discussed unless the body be much heated with meats and medicines. Therefore it is not altogether to be disproved which many say, that they have driven away a quartain by taking a draught of wine every day as soon as they came forth of their bed, in which some leaves of Sage had been infused all the night. Also it is good a little before the fit to anoint all the spine of the back with oyls heating all the nervous parts, such as are the oyl of Rue, Walnuts, of the Peppers, mixing therewith a little *Aqua vite*, but for this purpose the oyl of *Castoreum* which hath been boyled in an apple of *Coloquintida*, the Kernels taken out, upon hot coles to the consumption of the half part, mixing therewith some little quantity of the powders of Pepper, Pelitory of *Spain* and *Euphorbium*, is excellent. Certainly such like Inunctions are good not only to mitigate the vehemency of the terrible shaking, but also to provoke sweats; for because by their humid heat they discuss this humor being dull and rebellious to the expulsive faculty, for the Melancholy is as it were the dross and mud of the blood. Therefore if on the contrary the Quartain Feaver shall be caused by adust choler wee must hope for and expect a cure by refrigerating and humective medicines, such as Sorrell, Lettuce, Purslane, broths of the decoction of Cowcumbers, Gourds, Mellons and Pompions. For in this case if any use hot medicines, he shall make this humor most obstinate by the resolving of the subtiler parts. Thus *Trallianus* boasts that he hath cured these kinds of Quartane Feaver by the only use of refrigerating *Epithemae*s being often repeated a little before the beginning of the fit. And this is the sum of the Cure of true and legitimate intermitting Feavers. That is, of those which are caused by one simple humor, whereby the Cure of those which they call bastard intermitting Feavers, may be easily gathered and understood; as which are bred by a humor impure and not of one kind, but mixt or composed by admixture of some other matter; for example, according to the mixture of divers humors Phlegmatick and cholericke, the medicines must also be mixt, as if it were a confused kind of Feaver of a *Quotidian* and *Tertian*; it must be cured by a medicine composed of things evacuating flegm and choler.

Medicines.

What quartains must be cured with refrigerating things.

What bastard Agues are, and how they must be cured.

CHAP. XXXII.

Of an Aneurisma, that is, the dilatation, or springing of an Artery, Vein, or Sinew.

What it is.

An *Aneurisma* is a soft tumor yeelding to the touch, made by the blood and spirit powred forth under the flesh and Muscles, by the dilatation or relaxation of an Artery. Yet the Author of the definitions seems to call any dilatation of any venous vessell by the name of an *Aneurisma*. *Galen* calls an *Aneurisma* an opening made of the *Anastomasis*, of an Artery. Also an *Aneurisma* is made when an Artery that is wounded closeth too slowly, the substance which is above it being in the mean time agglutinated, filled with flesh and cicatrized, which doth not seldome happen in opening of Arteries unskilfully performed and negligently cured; therefore *Aneurismae*s are absolutely made by the *Anastomasis*, springing, breaking, *Erosion*, and wounding of the Arteries. These happen in all parts of the body, but more frequently in the throat, especially in women after a painfull travail. For when as they more strongly strive to hold their breath, for the more powerfull expulsion of the birth, it happens that the Artery is dilated and broken, whence follows an effusion of blood and spirits under the skin. The signs are, a swelling one while great, another small, with a pulsation and a colour not varying from the native constitution of the skin. It is a soft tumor, and so yeelding to the impression

In what parts they chiefly happen.

of the fingers that if it peradventure be small, it wholly vanisheth, the Arterious blood and spirits flying back into the body of the Artery, but presently as soon as you take your fingers away, they return again with like celerity. Some *Aneurismaes* do not only when they are pressed, but also of themselves make a sensible hissing, if you lay your ear near to them, by reason of the motion of the vitall spirit rushing with great violence through the straitness of the passage.

Wherefore in *Aneurismaes* in which there is a great rupture of the Artery, such a noise is not heard, because the spirit is carryed through a larger passage. Great *Aneurismaes* under the Arm pits, in the Groins and other part wherein there are large vessels, admit no cure, because so great an eruption of blood and spirit often follows upon such an incision, that death prevents both Art and Cure. Which I observed a few years ago in a certain Priest of Saint Andrews of the Arches, Mr. John Maillet, dwelling with a chief President Christopher de Thou. Who having an *Aneurisma* at the setting on of the shoulder about the bigness of a Wall-nut, I charged him, he should not let it be opened, for if he did it would bring him into manifest danger of his life, and that it would be more safe for him to break the violence thereof with double clothes steeped in the juyce of Night-shade & Houfseek, with new and whey cheese mixt therewith: Or with *Vnguentum de Bolo* or *Emplastrum contra rupturam* and such other refrigerating and astringent medicines, if he would lay upon it a thin plate of Lead, and would use shorter breeches that his doublet might serve to hold it too, to which he might fasten his breeches in stead of a swath, & in the mean time he should eschew all things which attenuate and inflame the blood, but especially he should keep himself from all great straining of his voice. Although he had used his diet for a yeer, yet he could not so handle the matter but that the tumor increased, which he observing goes to a Barber, who supposing the tumor to be of the kind of vulgar impostumes, applies to it in the Evening a Caustick causing an Eschar so to open it. In the Morning such an abundance of blood flowed forth from the tumor being opened, that he therewith astonished, implores all possible ayd, and bids that I should be called to stay this his great bleeding, and he repented that he had not followed my directions. Wherefore I am called, but when I was scarce over the threshold, he gave up his ghost with his blood. Wherefore I diligently admonish the young Chirurgion that he do not rashly open *Aneurismaes* unless they be smal in an ignoble part, and not indued with large vessels, but rather let him perform the cure after this manner. Cut the skin which lyes over it untill the Artery appear, and then separate it with your knife from the particles about it, then thrust a blunt and crooked needle with a thred in it under it, bind it, then cut it off and so expect the falling off of the thred of it self while nature covers the orifices of the cut Artery with new flesh, then the residue of the cure may be performed after the manner of simple wounds. The *Aneurismaes* which happen in the internall parts are incurable. Such as frequently happen to those who have often had the unctio and sweat for the cure of the French disease, because the blood being so attenuated and heated therewith that it cannot be contained in the receptacles of the Artery, it distends it to that largeness as to hold a mans Fist; Which I have observed in the dead body of a certain Taylor, who by an *Aneurisma* of the Arterious vein suddenly whilst he was playing at Tennis fell down dead, the vessel being broken: his body being opened I found a great quantity of blood powred forth into the capacity of the Chest, but the body of the Artery was dilated to that largeness I formerly mentioned, and the inner coat thereof was bony. For which cause within a while after I shewed it to the great admiration of the beholders in the Physicians School whilst I publicly dissected a body there; the whilst he lived said he felt a beating and a great heat over all his body by the force of the pulsation of all the Arteries, by occasion whereof he often swooned. Doctor Sylvius the Kings professor of Physick at that time forbad him the use of Wine, and wished him to use boyled water for his drink, and Curds and new Cheeses for his meat, and to apply them in form of Cataplasms upon the grieved and swoln part. At night he used a ptisan of Barly meal and Poppy-seeds, and was purged now and then with a Clyster of refrigerating and emollient things, or with Cassia alone, by which medicines he said he found himself much better. The cause of such a bony constitution of the Arteries by *Aneurismaes* is, for that the hot and fervid blood first dilates the Coats of an Artery, then breaks them; which when it happens, it then borrows from the neighbouring bodies a fit matter to restore the loosed continuity thereof.

This matter whilst by little and little it is dryed and hardened, it degenerates into a gristly or else a bony substance, just by the force of the same material and efficient causes, by which stones are generated in the reins and bladder. For the more terrestriall portion of the blood is dryed and condensed by the power of the unnaturall heat contained in the part affected with an *Aneurisma*; whereby it comes to pass that the substance added to the dilated and broken Artery is turned into a body of a bony consistence. In which the singular providence of nature, the handmaid of God is shewed, as that which, as it were by making and opposing a new wall or bank, would hinder and break the violence of the raging blood swelling with the abundance of the vitall spirits; unless any had rather to refer the cause of that hardness to the continuall application of refrigerating and astringent medicines

medicines. Which have power to condensate and harden, as may not obscurely be gathered by the writings of Galen. But beware you be not deceived by the forementioned signs; for sometimes in large Aneurismaes you can perceive no pulsation, neither can you force the blood into the Artery by the pressure of your fingers, either because the quantity of such blood is greater than which can be contained in the ancient receptacles of the Artery, or because it is condensate and concrete into clods, whereupon wanting the benefit of ventilation from the heart, it presently putrefies; Thence ensue great pain, a Gangren, and mortification of the part, and lastly the death of the Creature.

The End of the Seventh Book.

O F
PARTICULAR
TUMORS
AGAINST NATURE.

THE EIGHT BOOK.

The Preface.

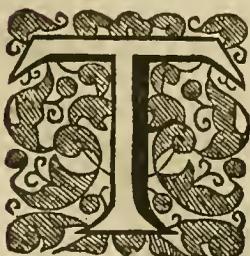

Because the Cure of diseases must be varied according to the variety of the temper, not only of the body in generall, but also of each part thereof; the strength; figure, form, site, and sense thereof being taken into consideration: I think it worth my pains, having already spoken of Tumors in generall, if I shall treat of them in particular which affect each part of the body, beginning with those which assail the head. Therefore the Tumor either affects the whole head, or else only some particle thereof, as the Eyes, Ears, Nose, Gums and the like. Let the Hydrocephalos, and Physocephalos be examples of those tumors which possess the whole head.

CHAP. I.

Of an Hydrocephalos or watry tumor which commonly affects the heads of Infants.

What it is.

The causes.

The Greeks call this disease Hydrocephalos, as it were a Dropsie of the Head, by a waterish humor; being a disease almost peculiar to Infants newly born. It hath for an externall cause the violent compression of the head by the hand of the Midwife or otherwise at the birth, or by a fall, contusion and the like. For hence comes a breaking of a vein, or Artery, and an effusion of the blood under the skin. Which by corruption becoming whayish, lastly degenerateth into a certain waterish humor. It hath also an inward cause, which is the abundance of serous and acrid blood, which by its tenuity and heat sweats through the pores of the vessels, sometimes between the Musculous skin of the head and the Pericranium, sometimes between the Pericranium and the skull, and sometimes between the skull and the membrane called Dura mater, and otherwhiles in the ventricles of the brain.

Differences by reason of place.

The signs of it, contained in the space between the Musculous skin and the *Pericranium*, are a manifest tumor without pain, soft, and much yeelding to the pressure of the fingers. The Signs when it remaineth between the *Pericranium* and the skull, are for the most part like the forenamed, unless it be that the Tumor is a little harder, and not so yeelding to the finger; by reason of the parts between it and the finger; And also there is somewhat more sense of pain. But when it is in the space between the skull and *Dura mater*, or in the ventricles of the Brain or the whole substance thereof, there is a dulness of the senses as of the sight and hearing; the tumor doth not yeeld to the touch, unless you use strong impression, for then it sinketh somewhat down, especially in infants newly born; who have their skulls almost as soft as waxe, and the junctures of their Sutures laxe, both by nature, as also by accident, by reason of the humor contained therein moistening and relaxing all the adjacent parts; the humor contained here lifts up the skull somewhat more high, especially at the meetings of the Sutures, which you may thus know, because the Tumor being pressed, the humor flies back into the secret passage of the Brain.

Signe.

To conclude, the pain is more vehement, the whole head more swollen, the forehead stands somewhat further out, the eye is fixt and immoveable, and also weeps by reason of the ferous humor sweating out of the brain.

Vesalius writes that he saw a girl of two yeers old, whose head was thicker than any mans head by this kind of Tumor, and the skull not bony, but membranous, as it useth to be in abortive births, and that there was nine pound of water ran out of it.

A History.

Abucrafis tels that he saw a child whose head grew every day bigger by reason of the watery moisture contained therein, till at length the tumor became so great, that his neck could not bear it neither standing nor sitting, so that he died in a short time. I have observed and had in cure four children troubled with this disease, one of which being dissected after it died, had a brain no bigger than a Tennis Ball. But of a Tumor and humor contained within under the *Cranium*, or Skull, I have seen none recover, but they are easily healed of an external Tumor.

Therefore whether the humor lye under the *Pericranium*, or under the musculous skin of the head, it must first be assayed with resolving medicines, but if it cannot be thus overcome, you must make an incision, taking heed of the Temporall Muscle, and thence press out all the humor, whether it resemble the washing of flesh newly killed, or blackish blood, or congealed or knotted blood, as when the tumor hath been caused by contusion; then the wound must be filled with dry lint, and covered with double boulders, and lastly, bound with a fitting ligature.

CHAP. XI.

Of a Polypus being an eating disease in the Nose.

The Polypus is a Tumor of the Nose against nature, commonly arising from the *Oethmoides* or spongy bone. It is so called, because it resembles the feet of a Sea Polypus in figure, and the flesh thereof in consistence. This Tumor stops the Nose, intercepting and hindering the liberty of speaking and blowing the Nose. *Celsus* saith the Polypus is a caruncle of excrecence, one while white, another while reddish, which adheres to the bone of the Nose, and sometimes fills the Nostrils hanging towards the lips, sometimes it descends back through that hole, by which the spirit descends from the Nose to the throttle; it grows so that it may be seen behind the *Vulva*, and often strangles a man by stopping his breath. There are five kinds thereof, the first is, a soft membrane, long and thin like the relaxed and depressed *Vulva*, hanging from the middle gristle of the nose, being filled with a Phlegmatick and viscid humor. This in expiration hangs out of the nose, but is drawn in and hid by inspiration; it makes one snaffle in their speech and snort in their sleep. The second hath hard flesh, bred of Melancholy blood without adustion, which obstructing the nostrils intercepts the respiration made by that part. The third, is flesh hanging from the Gristle, round, and soft, being the off-spring of Phlegmatick blood. The fourth is an hard Tumor, like flesh, which when it is touched yeelds a sound like a stone; it is generated of Melancholy blood dried, being somewhat of the nature of a *Scirrhus* confirmed and without pain.

The reason of the name.

Lib. 6. Cap. 8.

The differences hereof.

The fifth is as it were composed of many cancerous ulcers spread over the transverse surface of the gristle.

Of all these sorts of Polypi some are not ulcerated, others ulcerated, which send forth a stinking and strong smelling filth. Such of them as are painfull, hard, resisting, and which have a livid, or leaden color, must not be touched with the hand, because they favour of the Nature of a Cancer, as into which they oft degenerate; yet by reason of the pain which oppresses more violently, you may use the Anodyne medicines formerly described in a Cancer, such as this following.

Which of these admit no manual operation.

Rc Olei de vitell. ovorum ℥ ij, *Lytharg. auri*, & *Tuthie præp. an.* ℥ i, *succi plat. solani an.* ℥ i β, *Lapid. hematit.* & *camphoræ, an.* ℥ β. Let them be wrought a long time in a leaden mortar, and so make a medicine to be put into the nostrills. Those which are soft, loose and with-

An Anodyne.

out

out pain, are sometimes curable, being plucked away with an instrument made for that purpose, or else wasted by actuall cauteries put in through a pipe, so that they touch not the sound part; or by potentiall cauteries, as *Egyptiacum* composed of equall parts of all the simples with vitrioll which hath a faculty to waste such like flesh. *Aqua fortis* and oyl of vitrioll have the same faculty, for these take away a *Polypus* by the roots; for if any part thereof remain it will breed again. But Cauteries and acrid medicines must be put into the nostrills with this Caution, that in the mean time cold repelling and astringent medicines be applyed to the nose and parts about it to asswage the pain, and hinder the inflammation. Such as are *Vnguentum de bolo*, and *Vnguentum nutritum*, whites of Eggs beat with Rose leaves, and many other things of the like nature.

CHAP. III.

Of the Parotides, that is, Certain swellings about the Ears.

What it is.

The differenc-
ces.
Their signs and
Symptomes.

The *Parotis* is a Tumor against nature, affecting the Glandules and those parts seated behind and about the Ears, which are called the Emunctories of the brain; for these because they are loose and spongy, are fit to receive the excrements thereof. Of these some are criticall, the matter of the disease somewhat digested being sent thither by the force of nature. Others Symptomatically, the excrements of the brain increased in quantity or quality rushing thither of their own accord. Such abscesses often have great inflammation joyned with them, because the biting humor which flows thither is more vitiated in quality than in quantity. Besides also they often cause great pain, by reason of the distention of the parts indued with most exquisite sense, as also by reason of a Nerve of the fifth Conjugation spread over these parts; as also of the neighbouring membranes of the brain, by which means the patient is troubled with the Head-ach and all his face becomes swoln. Yet many times this kind of Tumor useth to be raised by a tough, viscous, and gross humor.

Prognostick.

This disease doth more grievously afflict young men than old; it commonly brings a Feaver and watching. It is difficult to be cured, especially when it is caused by a gross, tough, and viscid humor, sent thither by the *Crisis*.

The cure.

Lib. 3. de comp.
med. sec. Locos.
Hip. aph. 21.
lib. 1.

The cure must be performed by diet, which must be contrary to the quality of the humor in the temper and consistence of the meats. If the inflammation and redness be great, which indicate abundance of blood, Phlebotomy will be profitable, yea very necessary. But here we must not use the like judgment in application of locall medicines as we do in other tumors, as *Galen* admonisheth us; that is, we must not use repercutives at the beginning, especially if the abscess be criticall; for so we should infringe or foreslow the endeavors of nature forcibly freeing it self from the morbidique matter. But we must much less repell or drive it back if the matter which hath flowed thither be venenate, for so the reflow thereof to the noble parts would prove mortall. Wherefore the Chirurgeon shall rather assist nature in attracting and drawing forth that humor. Yet if the defluxion shall be so violent, if the pain so fierce that thence there may be fear of watchings and a Feaver, which may deject the powers, *Galen* thinks it will be expedient with many resolving medicines to mix some repelling. Wherefore at the beginning let such a Cataplasme be applyed.

Gentle resolving
medicines.

Rx. Far. bord. & sem. lin. ana ℥ ij, coquantur cum mulso. aut decocto cham. addendo but. recen. & olei cham. ana ℥ i, fiat cataplasma. And the following oyntment will also be good.

Rx. But. recen. ℥ ij; olei cham. & lilior. an. ℥ i, unguen. de Althea ℥ β, cer. e parum: make an oyntment to be applyed with moist and greasie wooll, to mitigate the pain: also somewhat more strong discussing and resolving medicines will be profitable, as:

Stronger re-
solvents.

Rx. Rad. Althee & bryon. an. ℥ ij, fol. ratae, puleg. orig. an. m. j, flo. chamem. melil. an. p. j, coquantur in hydromelite, pistentur, trajiciantur, addendo farin. fenugrac. orobi. an. ℥ i, pul. Ireos, cham. melilot. an. ℥ ij, olei aneth. rutac. an. ℥ i, fiat cataplasma. But if you determine to resolve it any more, you may use *Emplastrum Oxyroceum* & *Melilot-Plaister*. If the humor doth there concrete and grow hard, you must betake you to the medicines which were prescribed in the Chapter of the *Scirrhus*; but if it tend to suppuration, you shall apply the following medicine.

A Ripening
medicines.

Rx. Rad. liliorum & ceparum sub cineribus cocti. an. ℥ iij, Vitell. ovor. num. ij. axung. suilla & unguen. basilicon, an. ℥ i; sari. sem. lini ℥ i β, fiat Cataplasma. But if the matter do so require, let the tumor be opened as we have formerly prescribed.

C H A P. IIII.

Of the Epulis, or overgrowing of the flesh of the Gums.

The *Epulis* is a fleshy excrecence of the Gums between the teeth, which is by little and little oft-times encreased to the bigness of an Egge, so that it both hinders the speech and eating; it casts forth salivous and stinking filth, and not seldome degenerates into a *Cancer*, which you may understand by the propriety of the colour, pain and other accidents; for then you must by no means touch it with your hand. But that which doth not torment the Patient with pain, may be pluckt away; and let this be the manner thereof.

Let it be tyed with a double thred, which must be straiter twitched untill such time as it fall off; when it shall fall away, the place must be burnt with a cautery put through a trunk or pipe, or with *Aqua fortis*, or oyl of *Vitrioll*, but with great care that the sound parts adjoining thereto be not hurt, for if so be that it be not burnt, it usually returns.

I have often by this means taken away such large tumors of this kind, that they hung out of the mouth in no small bigness, to the great disfiguring of the face, which when as no Chirurgeon durst touch, because the flesh looked livid, I ventured upon because they were free from pain; and by taking them away and cauterizing the place, I perfectly healed them; not truly sodainly, and at once; for although I burnt the place after dissection; yet nevertheless they sprung up again, because a certain portion of the bone and sockets in which the Teeth stand fastened, were become rotten. I have often observed such like flesh by continuance of time to have turned into a gristly and bony substance. Wherefore the cure must be begun as speedily as may be; for being but little, and having fastened no deep roots, it is more easily taken away, being then only filled with a viscid humor, which in success of time is hardered, and makes the taking away thereof more difficult.

What it is.

tomes.The Chirurge-
call cure.Why the cure
must not be
deferred.

C H A P. V.

Of the Ranula.

Here is oft-times a tumor under the tongue, which takes away the liberty of pronuntiation or speech; wherefore the Greeks call it *Batrachium*, the Latins *Ranula*, because such as have this disease of the tongue, seem to express their minds by croaking rather than by speaking.

It is caused by the falling down of a cold, moist, gross, tough, viscid and phlegmatick matter, from the brain upon the tongue, which matter in colour and consistence resembles the white of an egge, yet sometimes it looks of a citrin or yellowish colour.

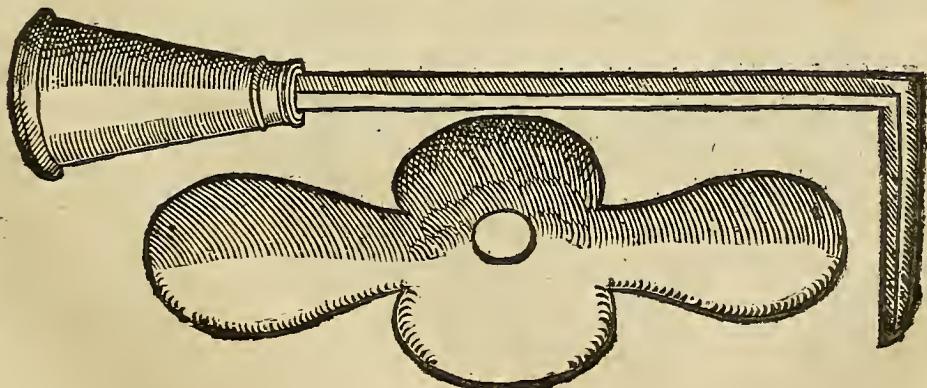

That you may safely perform the cure, you must open the Tumor rather with a cautery of hot Iron, than with a Knife, for otherwise it wil return again. The manner of opening of it must be thus. You shall get a bended hollow and perforated iron plate with a hole in the midst, and making the Patient to hold open his mouth, you shall so fit it, that the hole may be upon the part which must be opened. Then there you must open it with an hot Iron, for so you shall hurt no part of the mouth which is whole; but when you are ready to burn it, by thrusting your thumb under the Patients Chin, you may somewhat elevate the Tumor whereby you may open it with more certainty; when it is opened you must thrust out the matter contained therein, and then wash the Patients mouth with some barley water, hony, and Sugar of Roses; for so the ulcer will be safely and quickly healed.

The Reason
why it is so
called.

The Cause.

The Cure.

The delineation of the Iron plate and crooked actuall Cautery.

CHAP. VI.

Of the swelling of the Glandules, or Almonds of the throat.

Why the Glandules are called Almonds. Their use.

ature at the jaws near the roots of the Tongue, hath placed two Glandules opposite to one another; in figure and magnitude like to Almonds, whence also they have their name; their office is to receive the spittle falling down from the brain, both lest that the too violent falling down of the humor should hinder the tongue in speaking, as also that the tongue might alwayes have moisture, as it were laid up in store, lest by continuall speaking, it should grow dry and fail. For thus this spittle being consumed by feaverish heats, the Patients are scarce able to speak, unless they first moisten their tongue by much washing of their mouth.

The Cause of their tumor.

These Glandules because they are seated in a hot and moist place, are very subject to inflammations; for there flows into these oft-times together with the blood, a great quantity of crude, phlegmatick and viscous humors, whence arises a tumor; which is not seldome occasioned by drinking much and that vaporous wine, by too much Gluttony, and staying abroad in the open air.

Symptoms.

Swallowing is painfull and troublesome to the Patient, and commonly he hath a Feaver. Oft-times the neighbouring Muscles of the throttle and neck are so swoln together with these Glandules, (that as it usually happens in the *Squinzy*) the passage of the breath and air is stopped, and the Patient strangled.

Cure.

We resist this imminent danger by purging and blood-letting, by applying Cupping-Glasses to the Neck and shoulders, by frictions and ligatures of the extreme parts, and by washing and gargling the mouth and throat with astringent Gargarisms. But if they come to suppuration, you must with your incision Knife make way for the evacuation of the Pus, or Matter; but if on the contrary, these things performed according to art, defluxion be increased, and there is present danger of death by stopping and intercepting the breath, for the shunning so great and imminent danger, the top or upper part of the *Aspera arteria*, or Weazon must be opened, in that place where it uses to stand most out; and it may be done so much the safer, because the jugular veins, and arteries are furthest distant from this place, and for that this place hath commonly little flesh upon it. And that the incision may be the fittier made, the Patient must be wished to bend his head back, that so the Artery may be the more easily come to by the instrument; then you shall make an incision overthwart way with a crooked knife between two rings (not hurting nor touching the gristly substance) that is to say, the membrane which ties together the gristly rings being only cut; you shall then judg that you have made the incision large enough, when you shall perceive the breath to break out by the wound; the wound must be kept open so long, untill the danger of suffocation be past; and then it must be sowed up not touching the gristle: But if the lips of the wound shall be hard and callous; they must be lightly scarified, that so they may become bloody for their easier agglutination and union, as we shall shew more at large in the cure of Hare lips. I have had many in cure, who have recovered, that have had their Weazon together with the gristly rings thereof cut with a great wound, as we shall note when we shall come to treat of the cure of the wounds of that part.

Extreme diseases must have extreme remedies.

How you must open the Weazon.

CHAP. VII.

Of the inflammation and relaxation in the Vvula or Columella.

What the Vvula is, and what the use thereof.

The Vvula is a little body, spongy and somewhat sharpened to the form of a Pine apple, hanging even down from the upper and inner part of the palat, so to break the force of the Air drawn in, in breathing, and carryed to the Lungs, and to be as a quill to form and tune the voyce. It often grows above measure by receiving moisture falling down from the brain, becoming sharpe by little and little from a broader and more swoln Basis. Which thing causes many Symptoms; for by the continuall irritation of the distilling humor the Cough is caused, which also hinders the sleep and intercepts the liberty of speech; but also by hindering respiration the Patients cannot sleep unless with open mouth: they are exercised with a vain endeavouring to swallow (having as it were a morsell sticking in their jaws) and are in danger of being strangled.

The Cause of the swelling thereof.

Symptoms.

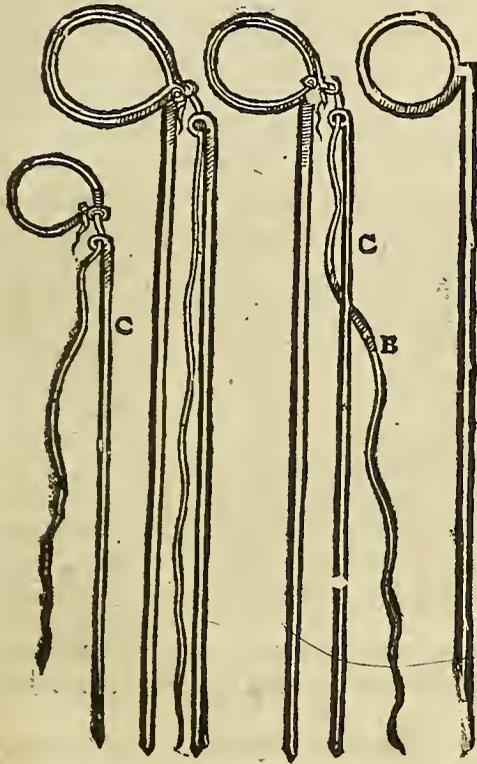

The Cure.

This disease must be resisted and assailed by purging, bleeding, Cupping, taking of Clysters, using astringent Gargles, and a convenient diet; but if it cannot thus be overcome, the cure must be tryed by a caustick of *Aqua fortis*, which I have divers times done with good success. But if it cannot be so done, it will be better to put to your hand, than through idleness to suffer the patient to remain in imminent and deadly danger of strangling; yet in this there must very great caution be used; for the Chirurgion shall not judg the Vvula fit to be touched with an instrument or caustick, which is swoln with much inflamed, or black blood after the manner of a *Cancer*; but he shall boldly put to his hand if it be longish, grow small

The cure by Chirurgery.

finall by little and little into a sharpe, loote and tort point; if it be neither exceeding red, neither swolne with too much blood, but whitish and without pain. Therefore that you may more easily and safely cut away, that which redounds and is superfluous, desire the Patient to sit in a light place, and hold his mouth open; then take hold of the top of the *Vvula* with your fizers, & cut away as much thereof as shall be thought unprofitable. Otherwise you shall bind it with the instrument here-under described; the invention of this instrument is to be ascribed to *Honoratus Tastellanus* that diligent and learned man, the Kings Physitian ordinary, and the chief Physitan of the Queen mother; Which also may be use in binding of *Polypi* and warts in the neck of the womb.

The Delineation of constrictory rings fit to twitch, or bind the Columella, with a twisted thred.

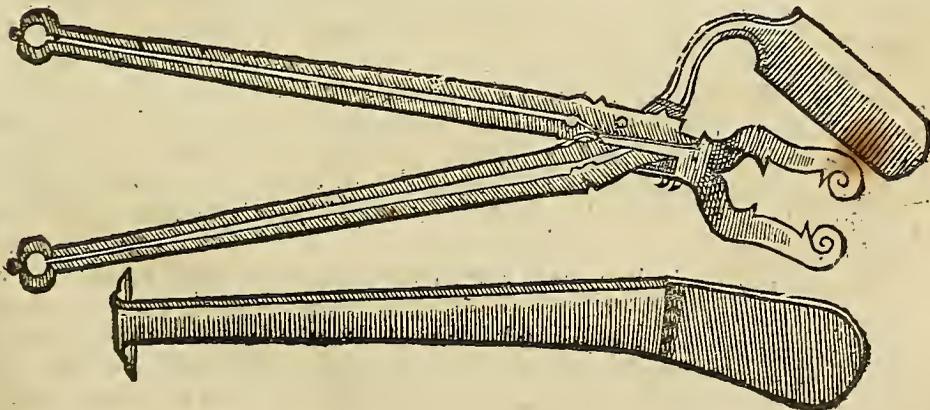

A. Shews the ring whose upper part is somewhat hollow.

B. A double waxed thred, which is couched in the hollownes of the ring, and hath a running, or loose knot upon it.

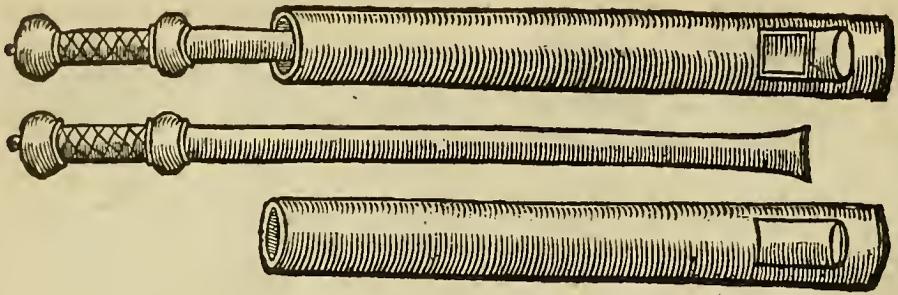

C. An iron rod, into the eye whereof the fore-mentioned double thred is put, and it is to twitch the *Columella* when as much thereof is taken hold of, as is unprofitable, and so to take it away without any flux of blood. When you would straiten the thred, draw it again through this iron rod, and so strain it as much as you shall think good, letting the end of the thred, hang out of the mouth. But every day it must be twitched harder than other, untill it fall away by means thereof, and so the part and patient be restored to health. I have delineated three of these instruments, that you may use which you will, as occasion shall be offered.

A Figure of the Speculum oris, by which the mouth is held and kept open whilst the Chirurgeon is busied in the cutting away or binding the Vvula.

But if an eating ulcer shall associate this relaxation of the *Vvula*, together with a flux of blood, then it must be burnt and seared with an hot iron, so thrust into a Trunk, or Pipe with an hole in it, that so no sound part of the mouth may be offended therewith.

A hollow Trunk with a hole in the side, with the hot iron inserted, or put therein.

CHAP. VIII.

Of the Angina, or Squinzy.

What it is.

The differences.

The first kind.

The Symptoms.

The Squinancy, or Squinzy, is a swelling of the jaws, which hinders the entering of the ambient air into the weazon, and the vapours and the spirit from passage forth, and the meat also from being swallowed. There are three differences thereof. The first torments the patient with great pain, no swelling being outwardly apparent, by reason the Morbifick humor lyes hid behind the almonds or Glandules at the *Vertebrae* of the neck, so that it cannot be perceived, unless you hold down the tongue with a spatula or the *Speculum oris*, for so you may see the redness and tumor there lying hid. The Patient cannot draw his breath, nor swallow down meat, nor drink; his tongue, (like a Gray-hounds after a course) hangs out of his mouth, and he holds his mouth open that so he may the more easily draw his breath; to conclude, his voyce is as it were drown'd in his jaws and nose; he cannot lye upon his back, but lying is forced to sit, so to breath more freely: and because the passage is stopt, the drink flies out at his nose; the eyes are fiery and swollen, and standing out of their orb. Those which are thus affected are often sodainly suffocated, a foam rising about their mouths.

The second kind.

The second difference is said to be that, in which the tumor appears inwardly, but little or scarce any thing at all outwardly, the tongue, Glandules, and jaws appearing somewhat swollen.

The third.

The third being least dangerous of them all, causes a great swelling outwardly, but little inwardly.

The Causes.

The Causes are either internall, or externall. The externall are a stroak, splinter or the like thing sticking in the Throat, or the excess of extreme cold, or heat. The internall causes are a more plentiful defluxion of the humors either from the whole body of the brain, which participate of the nature either of blood, choler or flegm, but seldome of Melancholy. The signs by which the kind and commixture may be known, have been declared in the generall treatise of tumors. The Squinzy is more dangerous, by how much the humor is less apparent within and without. That is less dangerous which shews it self outwardly, because such an one shuts not up the wayes of the meat, nor breath. Some dye of a Squinzy in twelve houres, other in two, four or seven dayes. Those (saith Hippocrates) which scape the Squinzy, the disease passes to the lungs, and they dye within seven dayes; but if they scape these dayes, they are suppurated; but also oftentimes this kind of disease is terminated by disappearing, that is, by an obscure reflux of the humor into some noble part, as into the Lungs (whence the *Empyema* proceeds) and into other principall parts, whose violating brings inevitable death; sometimes by resolution, otherwise by suppuration.

Hip. sect. 3.
prog. 2. A.
phor. 10. sect. 5

The way of resolution is the more to be desired; it happens when the matter is small, and that subtle, especially if the Physitian shall draw blood by opening a vein, and the Patient use fitting Gargarisms. A Criticall Squinzy divers times proves deadly by reason of the great falling down of the humor upon the throttle, by which the passage of the breath is sodainly shut up. Broths must be used made with Capons, and Veal seasoned with Lettuce, Purslain, Sorrell, and the cold feeds.

Dieti

If the Patient shall be somewhat weak, let him have potched Egges, and Barly Creams, the Barly being somewhat boyled with Raisons in water and Sugar, and other meats of this kind. Let him be forbidden wine, in stead whereof he may use *Hydromelita*, and *Hydrofachara* that is, drinks made of water and Hony, or water and Sugar as also the Syrups of dryed Roses, of Violets, Sorrell and Lemmons, and others of this kind. Let him avoid too much sleep. But in the mean time the Physitian must be carefull of all, because this disease

dicuate is of their kind, which brook no delays. Wherefore let the *Basilica* be presently opened, on that side the tumor is the greater; then within a short time after the same day, for evacuation of the conjunct matter, let the vein under the tongue be opened; let cupping-Glasses be applied, sometimes with scarification, sometimes without, to the neck and shoulders, and let frictions and painfull ligatures be used to the extreme parts. But let the humor impact in the part be drawn away by clysters and sharp suppositories. Whilst the matter is in defluxion, let the mouth without delay be washed with astringent gargarismes to hinder the defluxion of the humor, lest by its sodain falling down it kill the Patient, as it often happens, all the Physicians care and diligence notwithstanding. Therefore let the mouth be frequently washed with Oxycrate, or such a gargarism: R. Pomorum silvest. nu. iiii, sumach, Rosar. rub. an. m. ss. berber. ʒ ij, let them be all boyled with sufficient quantity of water to the consumption of the half, adding thereunto of the wine of soure Pomgranats, ʒ iiii, of *Diamoron* ʒ ij, let it be a little more boyled and make a gargle according to Art. And there may be other Gargarismes made of the waters of Plantain, Night-shade, Verjuice, Julep of Roses and the like. But if the matter of the defluxion shall be Phlegmatick, Alum, Pomgranat pill, Cypres nuts, and a little Vineger may be safely added. But on the contrary, repercussives must not be outwardly applyed, but rather Lenities, whereby the externall parts may be relaxed and rarified, and so the way be open either for the diffusing or resolving the portion of the humor. You shall know the humor to begin to be resolved, if the Feaver leave the Patient, if he swallow, speak and breath more freely, if he sleep quietly, and the pain begin to be much asswaged. Therefore then natures endeavour must be helped by applying resolved medicines, or else by using suppuratives inwardly and outwardly, if the matter seem to turn into Pus. Therefore let gargarismes be made of the roots of March-Mallows, Figs, Jujubes, damask Prunes, Dates, perfectly boyled in water. The like benefit may be had by Gargarismes of Cows milk with Sugar, by oyl of sweet Almonds, or Violets warm, for such things help forward supuration and asswage pain; let suppurating cataplasms be applyed outwardly to the neck and throat, and the parts be wrapped with wooll moistened with oyl of Lillies. When the Physitian shall perceive that the humor is perfectly turned into pus, let the patients mouth be opened with the *Speculum oris*, and the abscess opened with a crooked and long incision knife; then let the mouth be now and then washed with cleansing gargles; as R. *Aque bordei lib. ss. mellis ros. & syr. rosar. sic. au. ʒ i, fiat gargarisma.* Also the use of *ænomel*, that is, wine and Hony, will be fit for this purpose. The ulcer being clenfed by these means, let it be cicatrized with a little roch-Alum added to the former gargarismes.

CHAP. IX.

Of the Bronchocele, or Rupture of the throat.

That which the French call *Goetra*, that the Greeks call *Bronchocele*, the Latins *Gutturis Hernia*, that is, the Rupture of the throat. For it is a round tumor of the throat, the matter whereof coming from within outwards, is contained between the skin and weazon; it proceeds in women from the same cause as an *Aneurisma*.

But this generall name of *Bronchocele* undergoes many differences; for sometimes it retains the nature of *Melicerides*, other whiles of *Steatoma's*, *Atheoroma's* or *Aneurisma's*, in some there is found a fleshy substance having some small pain; some of these are small, others so great, that they seem almost to cover all the throat; some have a Cist, or bag, others have no such thing; all how many so ever they be, and what end they shall have, may be known by their proper signs; these which shall be curable, may be opened with an actuall or potentiall cautery, or with an incision knife. Hence if it be possible, let the matter be presently evacuated, but if it cannot be done at once, let it be performed at divers times, and discussed by fit remedies, and lastly, let the ulcer be consolidated and cicatrized.

The reason of
the name.

The differences.

The Cures.

CHAP. X.

Of the Pleurisie.

What it is.

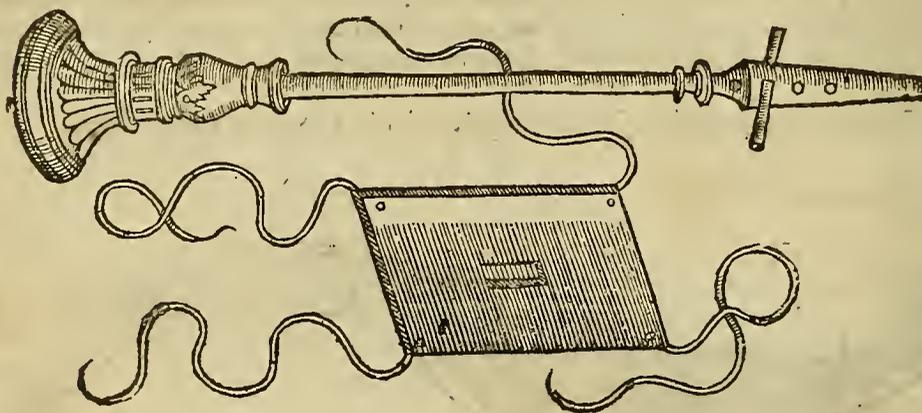

Of a Pleurisie coming to suppuration.

Of the change thereof into an *Empyema*.Of the aperition of the side in an *Empyema*.

The Pleurisie is an inflammation of the membrane, investing the ribs, caused by subtile and choleric blood, springing upwards with great violence from the hollow vein into the *Azygos*, and thence into the intercostall veins, and is at length powred forth into the emptie spaces of the intercostall muscles, and the mentioned membrane. Being contained there, if it tend to suppuration, it commonly infers a pricking pain, a Feaver and difficulty of breathing. This suppurated blood is purged and evacuated one while by the mouth; the Lungs sucking it, and so casting it into the Weazon, and so into the mouth, otherwhiles by urine, and sometimes by stool.

But. if nature being too weak, cannot expectorate the purulent blood poured forth into the capacity of the chest, the disease is turned into an *Empyema*, wherefore the Chirurgion must then be called, who beginning to reckon from below upwards, may make a vent between the third and fourth true and legitimate ribs; and that must be done either with an actual or potentiall cautery, or with a sharpe knife drawn upwards, towards the back, but not downwards, lest the vessels should be violated which are disseminated under the rib. This aperition may be safely and easily performed by this actuall cautery; it is perforated with four holes, through one whereof there is a pin put higher or lower according to the depth and manner of your incision: then the point thereof is thrust through a plate of Iron perforated also in the midst, into the part designed by the Physitian, lest the wavering hand might peradventure touch, and so hurt the other parts not to be medled withall. This same plate must be somewhat hollowed, that so it might be more easily fitted to the gibbous side, and bound by the corners on the contrary side with four strings. Wherefore I have thought good here to express the figures thereof.

The Figure of an actuall cautery with its plate fit to be used in a Pleurisie.

But if the patient shall have a large body, Chest and ribs, you may divide and perforate the ribs themselves with a Trepan; howsoever the aperition be made, the *pus* or matter must be evacuated by little and little at severall times; and the capacity of the Chest cleaned from the purulent matter by a detergent injection of vj ounces of Barley water, and ζ ij . honey of Roses, and other the like things mentioned at large in our cure of wounds.

CHAP. XI.

Of the Dropsie.

What the Dropsie is.

The differences thereof.

The Dropsie is a Tumor against nature by the abundance of waterish humor, or flatulencies, or Phlegm, gathered one while in all the habit of the body, otherwhiles in some part, and that especially in the capacity of the belly between the *Peritonæum* and entrails. From this distinction of places and matters there arise divers kinds of Dropsies. First, that Dropsie which fills that space of the belly, is either moist or dry. The moist is called the *Ascites*, by reason of the similitude it hath with a leather bottle, or *Borachio*, because the waterish humor is contained in that capacity, as it were in such a vessell.

The dry is called the *Tympanites*, or Tympany, by reason the belly swollen with wind sounds like a *Tympanum*, that is, a Drum. But when the whole habit of the body is distended with

with a phlegmatick humor, it is called *Anasarca* or *Leucophlegmatia*. In this last kind of Dropsie the lower parts first swell, as which by reason of their site are more subject to receive defluxions, and more remote from the fountain of the native heat; wherefore if you presse them down the print of your finger will remain sometime after; the patients face will become pale and puffed up, whereby it may be distinguished from the two other kinds of Dropsie. For in them first the belly, then by a certain consequence the thighs and feet do swell. There are besides also particular Dropsies, contained in the strait bounds of certain places, such are the *Hydrocephalus* in the head; the *Bronchocele* in the throat; the *Pleurocele* in the Chest; the *Hydrocele* in the *Scrotum*, or Cod; and so of the rest. Yet they all arise from the same cause; that is, the weaknes or defect of the altering or concocting faculties, especially of the liver, which hath been caused by a *Scirrhus*, or any kind of great distemper, chiefly cold, whether it happen primarily, or secondarily by reason of some hot distemper dissipating the native and inbred heat, such a Dropsie is incurable; or else it comes by consent of some other higher or lower part; for if in the Lungs, Midriff, or Reins there be any distemper, or disease bred, it is easily communicated to the gibbous part of the Liver, by the branches of the hollow vein, which run thither. But if the mischief proceed from the Spleen, Stomach, Mesentery Guts, especially the *jejunum* and *Ileum*, it creeps into the hollow side of the liver by the meseraick veins, and other branches of the *Vena porta* or Gate vein. For thus such as are troubled with the *Asthma*, Ptsick, Spleen, Jaundise, and also the Phrensie, fall into a Dropsie.

The Symptoms.

The Causes.

How divers diseases turn into Dropsies.

Lastly, all such as have the menstruall or hæmorrhoidall blood suppressed or too immoderately flowing contrary to their custome, either overwhelms, diminisheth or extinguisheth the native heat; no otherwise than fire, which is suffocated by too great a quantity of wood; or dieth and is extinguished for want thereof. We must look for the same from the excrements of the belly or bladder, cast forth either too sparingly or too immoderately: Or by too large quantity of meats too cold and rashly devoured without any order; To conclude, by every default of externall causes, through which occasion, error may happen in diet or exercise.

The *Ascites* is distinguished from the two other kinds of Dropsies, both by the magnitude of the efficient cause, as also by the violence of the Symptoms, as the dejected appetite, thirst, and swelling of the *Abdomen*. And also when the body is moved or turned upon either side, you may hear a sound as of the jogging of water in a vessell half full. Lastly, the humor is diversly driven upwards or downwards, according to the turning of the body and compression of the *Abdomen*; It also causeth various Symptoms by pressure of the parts to which it floweth. For it causeth difficulty of breathing and the cough by pressing the Midriffe; by sweating through into the capacity of the Chest it causeth like Symptoms as the *Empyema*. Besides also the patients often seem, as it were, by the ebbing and flowing of the waterish humor, one while to be carried to the skies, and another while to be drowned in the water, which I have learnt not by reading of any author, but by the report of the patients themselves. But if these waterish humors be fallen down to the lower parts, they suppress the excrements of the guts and bladder by pressing and straitning the passages. When the patient lies on his back the tumor seems lesse, because it is spread on both sides; On the contrary when he stands or sits, it seems greater, for that all the humor is forced or driven into the lower belly, whence he feels a heaviness in the *Pecten* or share. The upper parts of the body fall away by defect of the blood fit for nourishment in quality and consistence, but the lower parts swell by the flowing down of the serous and waterish humor to them. The pulse is little, quick, and hard with tention.

The Signs of an Ascites.

The Symptoms.

This disease is of the kind of Chronicall or long diseases; wherefore it is scarce, or never cured, especially in those who have it from their mothers womb, who have the Action of their stomach depraved, and those who are cachectick, old; and lastly, all such as have the naturall faculty languishing and faulty.

Prognosticks.

On the contrary, young and strong men, especially if they have no fever, and finally all who can endure labour, and those exercises which are fit for curing this disease, easily recover, principally if they use a Physitian before the water which is gathered together do putrefie and infect the bowels by its contagion.

CHAP. XII.

Of the cure of the Dropsie.

The beginning of the cure must be with gentle and mild medicines; neither must we come to a *Paracentesis* unless we have formely used and tried these. Therefore it shal be the part of the Physitian to prescribe a drying diet, and such medicines as carry away water, both by stool and urine. *Hippocrates* ordains this powder for Hydropick persons. *Rx* *Canthar. ablati capitib. & alia* ʒʒ. *Comburentur in furno, & fiat pulvis;* of which administer two grains in white wine, for nature helped by this, and the like remedies hath not seldome been seen to have cured the Dropsie.

Hip. lib. 4 de acut. & lib. de intern.

But that we may hasten the cure, it will be available to stir up the native heat of the part by application of those medicines which have a discussing force; as bags, baths, ointments, and Emplaisters. Let bags be made of dry and harsh Bran, Oats, Salt, Sulphur, being made hot, or for want of them, of Sander, or Ashes often heated.

Bags.

Baths.

Liniments.

Emplaisters.

Vesicatories.

The more effectually baths are salt, nitrous, and sulphurous waters, whether by nature or art, that is, prepared by the dissolution of salt, niter, and Sulphur; to which if Rue, Marjoram, the leaves of Fennell, and tops of Dill, or *Stachus*, and the like be added, the business will goe better forwards. Let the ointments be made of the oyl of Rue, Dill, Baies, and Squills, in which some *Euphorbium*, Pellitory of *Spain*, or Pepper have been boiled. Let plaisters be made of Frankincense, Myrrh, Turpentine, *Costus*, Bayberries, English galengall, hony, the dung of Oxen, Pigeons, Goats, Horses, and the like, which also may be applied by themselves. If the disease continue, we must come to *Sinapismes* and *Phanigmes*, that is, to rubrifying and vesicatory medicines. When the blisters are raised, they must be anointed again, that so the water may by little and little flow so long untill all the humor be exhausted, and the patient restored to health.

Gal. lib. de facult. natur. 1.

Galen writes, the Husbandmen in *Asia*, when they carried wheat out of the Country into the city in *Cars*, when they wil steal away and not be taken, hide some stone jugs fill'd with water in the midst of the wheat; for that will draw the moisture through the jugs into it self, and encrease both the quantity and weight. When certain pragmaticall Physitians had read this, they thought that wheat had force to draw out the water, so that if any sick of the Dropsie should be buried in a heap of wheat, it would draw out all the water.

Divers opinions of *Paracentesis*, or opening of the belly. Reasons against it.

But if the Physitian shall profit nothing by these means, he must come to the exquisitely chief remedy, that is, to *Paracentesis*. Of which because the opinions of the ancient Physitians have been divers, we will produce and explain them.

Those therefore which disallow *Paracentesis*, conclude it dangerous for three reasons. The first is because by pouring out the contained water, together with it, you dissipate and resolve the spirits, and consequently the naturall, vitall, and animall faculties. Another opinion is, because the Liver wanting the water by which formerly it was born up; thence forward hanging down by its weight, depresseth and draweth downwards the midriff and the whole Chest, whence a dry cough, and a difficulty of breathing proceed. The third is, because the substance of the *Peritonæum*, as that which is nervous, cannot be pricked or cut without danger, neither can that which is pricked or cut be easily agglutinated and united, by reason of the spermatick and bloudlesse nature thereof. *Erasistratus* moved by these reasons condemned *Paracentesis* as deadly: also he perswaded that it was unprofitable for these following reasons, *viz.* because the water powred forth, doth not take away with it the cause of the Dropsie, and the distemper and hardness of the Liver, and of the other bowels, whereby it comes to pass that by breeding new waters they may easily again fall into the Dropsie. And then the feaver, thirst, the hot and drie distemper of the bowels, all which were mitigated by the touch of the included water, are aggravated by the absence thereof, being powred forth: which thing seemeth to have moved *Avicen* and *Gordonius* that he said none; the other said very few lived after the *Paracentesis*; but the refutation of all such reasons is very easie.

Erasistratus his Reasons against it.

Reasons for it.

For, for the first *Galen* infers, that harmful dissipation of spirits, and resolving the faculties happens, when the *Paracentesis* is not diligently, and artificially performed. As in which the water is presently powred forth; truly if that reason have any validity, Phlebotomy must seem to be removed far from the number of wholsome remedies, as whereby the blood is poured forth, which hath far more pure and subtil spirits, than those which are said to be diffused and mixed with the Dropsie waters. But that danger which the second reason threatens shall easily be avoided; the patient being desired to lie upon his back in his bed, for so the Liver will not hang down. But for the third reason, the fear of pricking the *Peritonæum*, is childish: for those evils which follow upon wounds of the nervous parts, happen by reason of the exquisit sense of the part, which in the *Peritonæum* ill affected & altered by the contained water, is either none or very smal. But reason and experience teach many nervous parts, also the very membranes themselves being far removed from a fleshy substance, being wounded admit cure; certainly much more the *Peritonæum*, as that which adheres so straitly to the muscles of the *Abdomen*, that the dissector cannot separate it from the flesh, but with much labor. But the reason which seems to argue the unprofitableness of the *Paracentesis* is refuted by the authority of *Celsus*. I, saith he, am not ignorant that *Erasistratus* did not like *Paracentesis*; for he thought the Dropsie to be a disease of the Liver, and so that it must be cured, and that the water was in vain let forth, which the Liver being vitiated, might grow again. But first this is not the fault of this bowel alone, and then although the water had his originall from the Liver, yet unless the water which stayeth there contrary to nature being evacuated, it hurteth both the Liver, and the rest of the inner parts, whilst it either encreaseth their hardness, or at the least keepeth it hard, and yet notwithstanding it is fit the body be cured. And although the once letting forth of the humor profit nothing, yet it makes way for medicines, which while it was there contained, it hindered. But this serous, salt, and corrupt humor is so far from being able to

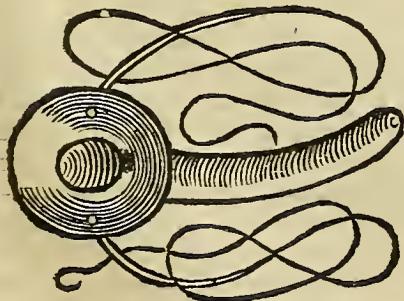

Lib. 3. cap. 21.

mitigate

mitigate a fever and thirst, that on the contrary it increaseth them. And also it augmenteth the cold distemper, whilst by its abundance it overwhelms and extinguisheth the native heat. But the authority of *Celius Aurelianus* that most noble Physitian, though a Methodist, may satisfie *Avicen* and *Gordonius*. They, saith he, which dare avouch that all such as have the water let out by opening their belly have died, do lie; for we have seen many recover by this kind of remedy: but if any died, it happened either by the default of the flow or negligent administration of the *Paracentesis*. I will add this one thing which may take all error of controversies: we unwisely doubt of the remedy when the patient is brought to that necessity, that we can only help him by that means. Now must we shew how the belly ought to be opened. If the Drop sic happen by fault of the Liver, the section must be made on the left side; but if of the Spleen, in the right: for if the patient should lie upon the side which is opened, the pain of the wound would continually trouble him, and the water running into that part where the section is, would continually drop; whence would follow a dissolution of the faculties. The Section must be made three fingers breadth below the Navell, to wit, at the side of the right muscle, but not upon that which they call the *Linea Alba*; neither upon the nervous parts of the rest of the muscles of the *Epigastrium*; that so we may prevent pain and difficulty of healing. Therefore we must have a care that the patient lie upon his right side, if the incision be made in the left, or on the left, if on the right. Then the Chirurgeon both with his own hand, as also with the hand of his servant assisting him, must take up the skin of the belly, with the fleshy pannicle lying under it, and separate them from the rest; then let him dividethem so separated with a Section even to the flesh lying under them, which being done, let him force as much as hee can the divided skin upwards towards the stomach, that when the wound, which must presently be made in the flesh lying there-under, shall be consolidated, the skin by its falling therein, may serve for that purpose: then therefore let him divide the musculous flesh and *Peritoneum* with a small wound, not hurting the Gall or Guts.

Then put into the wound a trunk, or golden, or silver crooked pipe, of the thickness of a Goose's-quill, and of the length of some halfa finger. Let that part of it which goes into the capacity of the belly have something a broad head, and that perforated with two small holes, by which a string being fastened, it may be bound so about the body, that it cannot be moved, unless at the Chirurgeons pleasure. Let a sponge be put into the pipe, which may receive the dropping humor: and let it be taken out when you would evacuate the water: but let it not be poured out all together, but by little and little for fear of dissipation of the spirits, and resolution of the faculties, which I once saw happen to one sick of the Drop sic. He being impatient of the disease and cure thereof, thrust a Bodkin into his belly, and did much rejoyce at the pouring forth of the water, as if he had been freed from the humor and the disease, but died within a few houres, because the force of the water running forth, could by no means be staid, for the incision was not artificially made. But it will not be sufficient to have made way for the humor by the means aforementioned, but also the external orifice of the pipe must be stopped & strengthened by double cloaths, and a strong ligature, lest any of the water flow forth against our wils. But we must note that the pipe is not to be drawn out of the wound, before as much water shall be issued forth as we desire, and the tumor requireth; for once drawn forth, it cannot easily be put in again, and without force and pain be fitted to the lips of the wound, because the skin and fleshy pannicle cover it by their falling into the wound of the flesh or muscle. But whilst the water is in evacuation, we must have a diligent care of feeding the patient, as also of his strength, for if that fail, and he seem to be debilitated, the effusion of the water must be staid for some daies, which at the length performed according to our desire, the wound must be so consolidated that the Chirurgeon beware it degenerate not into a *Fistula*.

CHAP. XIII.

Of the tumor and relaxation of the Navell.

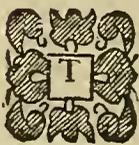

The divers
causes thereof.

The *Exomphalos* or swelling of the Navel, is caused by the *Peritonæum*, either relaxed or broken: for by this occasion oft-times the guts, and oft-times the kall, fall into the seat of the Navell, and sometimes superfluous flesh is there generated; otherwise this tumor is as an *Aneurisma* by too great a quantity of blood poured forth in that place: otherwise by a flatulent matter, and sometimes by a waterish humor. If the humor be occasioned by the kall, the part it self will retain his proper colour, that is, the colour of the skin; the tumor will be soft and almost without pain, and which will reside without noise, either by the pressure of your fingers, or of it self when the Patient lieth on his back; but tumor caused by the guts, is more unequall, and when it is forced in by the pressure of your fingers, there is such a noise heard, as in the *Exterocele*; but if the tumor proceed of superfluous flesh it will be harder and more stubborn, not easily retiring into the body, although the patient lie upon his back, and you presse it with your fingers.

Signs hereof
occasioned by
the kall.By the guts.
By flesh.By wind.
By a waterish
humor.
By bruised
blood.
Which may be
cured by Chi-
rurgery, which
nor.
The cure by
Chirurgery.

The tumor is softer which proceeds of wind, but which will not retire into the body, & sounds under your nail like a taber. If the swelling be caused by a waterish humor, it hath all things common with the flatuous tumor, except that it is not so visible, and without noise. If it be from effusion of blood, it is of a livid colour, but if the effused blood shall be arteriall, then there are the signs of an *Aneurisma*. Wherefore when the tumor is caused by the guts, kall, wind or a waterish humor, it is cured by Chirurgery: but not if it proceed from a fleshy excrescence or suffusion of blood. The tumor of the navell proceeding from the kall and guts, the Patient must lie upon his back to be cured, and then the kall, and guts, must with your fingers be forced into their due place: then the skin with which the tumor is circumscribed must be taken up with your fingers, and thrust through with a needle, drawing after it a double twined and strong thred, then it must be scarified about the sides, that so it may be the easier agglutinated. Then must it be thrust through with a needle three or four times, according to the manner and condition of the distention and tumor. And so twitch it strongly with a thred, that the skin which is so bound may at length fall off together with the ligatures. But also you may cut off the skin so distended even to the ligature, and then cicatrize it, as shall be fit. A flatulent tumor of the navell shall be cured with the same remedies, as we shall hereafter mention in the cure of a windy rupture, but the watery may be poued forth by making a small incision. And the wound shall be kept open, so long, untill all the water be drained forth.

CHAP. XIII.

Of the Tumors of the Groins and Cods called *Herniæ*, that is, Ruptures.These are
only 3. sorts
of Ruptures.

The ancient Physicians have made many kinds of Ruptures, yet indeed there are only three to be called by that name, that is, the *Intestinalis*, or that of the guts, the *Zybalis*, or that of the kall, and that which is mixed of them both. The other kinds of Ruptures have come into this order, rather by similitude, than any truth of the thing: for in them the gut or kall doe not forsake their places.

Bubonocele.
Enterocoele and
*Epiplocoele.**Hydrocele.*
*Physocoele.**Sarcocele.*
Cirrocœle.

The Causes.

The Signs.

The Greeks have given to all these severall names, both from the seat of the tumor, as also from their matter. For thus they have called an unperfect rupture which descends not beyond the Groins, nor falls down into the cods, *Bubonocele*: but the compleat which penetrates into the cod, if it be by falling down of the gut, *Enterocoele*: if from the kall, *Epiplocoele*: if from them both together, they name it *Enteroeppiocoele*: but if the tumor proceed from a waterish humor, they term it *Hydrocele*: if from wind, *Physocoele*; if from both, *Hydrophysocoele*; if a fleshy excrescence shall grow about the testicle, or in the substance thereof, it is named *Sarcocele*. If the veins interwoven, and divaricated divers wayes shall be swollen in the cod and testicles, the tumor obtains the name of a *Cirrocœle*. But if the humors shall be shut up or sent thither, the name is imposed upon the tumor, from the predominant humor, as we have noted in the beginning of our Tractate of Tumors. The causes are many, as all too violent motions, a stroak, a fall from a high place, vomiting, a cough, leaping, riding upon a trotting horse, the sounding of trumpets, or sackbuts, the carrying, or lifting up of a heavy burden, racking, also the too immoderate use of viscid and flatulent meats; for all such things may either relax or break the *Peritonæum*, as that which is a thin and extended membrane. The signs of a *Bubonocele* are a round tumor in the groin, which pressed, is easily forced in. The signs of an *Enterocoele* are a hard tumor in the cod, which forced, returneth back and departeth with a certain murrur and pain; but the tumor proceeding of the kall, is lax and feels soft like wool, and which is more difficultly forced in,

in, than that which proceeds from the guts, but yet without murmuring and pain: for the substance of the guts, seeing it is one, and continued to it self, they doe not only mutually succeed each other, but by a certain consequence doe, as in a dance draw each other, so to avoid distention, which in their membranous body cannot be without pain, by reason of their change of place from that which is naturall, into that against nature: none of all which can befall the kall, seeing it is a stupid body, and almost without sense, heavy, dull, and immoveable. The signs that the *Peritonæum* is broken, are the sudden increase of the tumor, and a sharp and cutting pain; for when the *Peritonæum* is only relaxed, the tumor groweth by little and little, and so consequently with small pain; yet such pain returns so often, as the tumor is renewed by the falling down of the gut, or kall, which happens not the *Peritonæum* being broken: for the way being once open, and passable to the falling body, the tumor is renewed without any distention, and so without any pain to speak of. The rest of the signs shall be handled in their places. Sometimes it happens that the guts, and kall, do firmly adhere to the proceffe of the *Peritonæum*, that they cannot be driven back into their proper feat. This stubborn adhesion happens by the intervention of the viscid matter, or by means of some excoriation caused by the rude hand of a Chirurgion, in too violently forcing of the gut, or kall, into their place. But also, too long stay of the gut in the cod, and the neglect of wearing a Trusse, may give occasion to such adhesion. A perfect and inveterate rupture by the breaking of the proceffe of the *Peritonæum* in men of full growth, never, or very seldome admits of cure. But you must note, that by great ruptures of the *Peritonæum*, the guts may fall into the cod, to the bigness of a mans head, without much pain and danger of life, because the excrements, as they may easily enter, by reason of the largeness of the place and rupture, so also they may easily return.

What rupture is incurable.

CHAP. XV.

Of the cure of Ruptures.

Because children are very subject to Ruptures, but those truly not fleshy or various, but watry, windy, and especially of the guts, by reason of continuall and painfull crying and coughing: Therefore in the first place we will treat of their cure. Wherefore the Chirurgion, called to restore the gut which is fallen down, shall place the child, either on a table, or in a bed; so that his head shall be low, but his buttocks and thighe higher; then shall he force with his hands by little and little, and gently, the gut into his proper place; and shall foment the groin with the astringent fomentation, described in the falling down of the womb. Then let him apply this remedy. *℞* *Præscript. decoctionis quantum sufficit, farinæ hordei & fabarum, an. ℥ij, pulver. Aloes, Mastiches, Myrtyll. & Sarcoco. an. ℥ss, Boli Armeni ℥ij.* Let them be incorporated and made a cataplasme according to Art. For the same purpose he may apply *Emplastrum contra Rupturam*: but the chief of the cure consists in folded clothes, and trusses, and ligatures artificially made, that the restored gut may be contained in its place, for which purpose he shall keep the child seated in his cradle for 30 or 40 dayes, as we mentioned before; and keep him from crying, shouting, and coughing. *Actius* bids steep paper 3 dayes in water, and apply it made into a ball to the groin, the gut being first put up; for that remedy by 3 days adhesion will keep it from falling down. But it will be, as I suppose, more effectually, if the paper be steeped not in common, but in the astringent water, described in the falling down of the womb. Truly I have healed many by the help of such remedies, and have delivered them from the hands of Gelders, which are greedy of childrens testicles, by reason of the great gain they receive from thence. They by a crafty cozenage, perswade the Parents, that the falling down of the gut into the cod, is incurable: which thing notwithstanding experience convinceth to be false, if so be the cure be performed according to the forementioned manner, when the *Peritonæum* is only relaxed, and not broken: for the proceffe thereof by which the gut doth fall as in a steep way, in progress of time and age is straitned and knit together, whilst also in the mean time the guts grow thicker.

A certain Chirurgion who deserveth credit, hath told me that he hath cured many children as thus: He beats a loadstone into fine powder, and gives it in pap, and then he anoints with hony the groin, by which the gut came out, and then strewed it over with fine filings of iron. He administered this kind of remedy for ten or twelve dayes: The part, for other things being bound up with a ligature and trusse as was fitting. The efficacy of this remedy seemeth to consist in this; that the loadstone by a natural desire of drawing the iron which is strewed upon the groin, joins to it the fleshy and fatty particles interposed between them, by a certain violent impetuosity, which on every side pressing and bending the looseness of the *Peritonæum*, yea verily adjoining themselves to it, in proceffe of time by a firm adhesion intercept the passage and falling down of the gut or kall; which may seem no more abhorring from reason, than that we behold the loadstone it self through the thickness of a table, to draw iron after it any way. The same Chirurgion affirmed, that he frequently and happily used the following medicine. He burnt into ashes in an oven red snails; shut up in an earthen pot, and gave the powder of them to little children in pap, but to those which were bigger, in broth.

Another way to cure ruptures.

The reason of this cure.

Another medicine.

But

A notable
History.

But we must despair of nothing in this disease, for the cure may happily proceed in men of full growth, as of fortie year old, who have filled the three dimenſions of the body, as this following relation teſtifies.

There was a certain Priest in the Parish of *St. Andrews*, called *John Moret*, whose office it was to sing an Epistle with a loud voice as often as the solemnity of the day, and the thing required. Wherefore seeing he was troubled with the *Enterocoele*, he came to me, requiring help, saying, he was troubled with a grievous pain, especially then, when he stretched his voice in the Epistle.

When I had seen the bigness of the *Enterocoele*, I perswaded him to get another to serve in his place; so having gotten leave of *M. Curio* Clerk, and Deacon of Divinity, he committed himself unto me: I handled him according unto Art, and commanded him he should never go without a Trusse; and he followed my directions. When I met him some five or six years after, I asked him how he did, he answered very well, for he was wholly freed from the disease with which he was formerly troubled; which I could not perswade my self of, before that I had found that he had told me the truth, by the diligent observation of his genitals. But some six months after, he dying of a Pleurisie. I came to *Curio's* house where he died, and desired leave to open his body, that I might observe whether nature had done any thing at all in the passage through which the gut fell down: I call God to witness, that I found a certain fatty substance about the proceſſe of the *Peritonæum* about the bigness of a little egg, and it did stick so hard to that place, that I could scarce pull it away without the rending of the neighbouring parts. And this was the speedy cause of his cure. But it is most worthy of observation, and admiration, that Nature but a little helped by Art, healeth diseases which are thought incurable. The chief of the cure consists in this, that wee firmly stay the gut in its place, after the same manner as these two figures shew.

We must never
despair in dis-
eases if so be
nature be affo-
ciated by art.

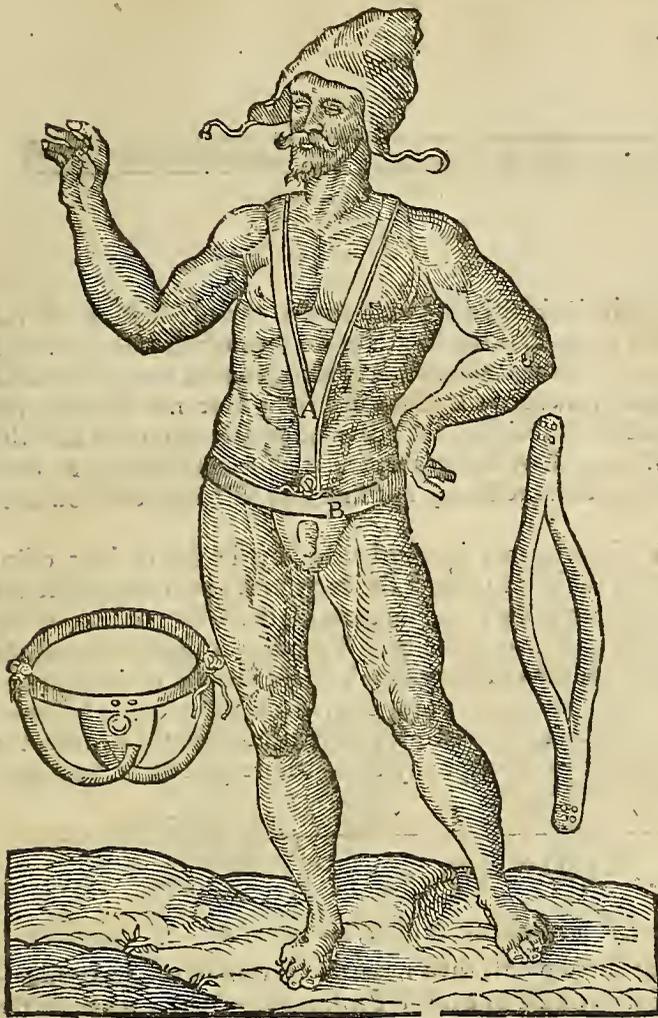

The figure of a man broken on one side, wearing a Trusse, whose bolster must have three Tuberosities, two on the upper, and one on the lower part; and there must be a hollownes between them in the midst, that they may not too straitly press the shankone, and so cause pain. The manner of such a Trusse, I found out not long agoe, and it seemed better and safer than the rest for to hinder the falling down of the gut and kall.

- A. Shews the shoulderband which is tied before and behind to the girdle of the Trusse.
B. The Trusse.
C. The Cavity left in the midst of the Tuberosities.

In the mean time we must not omit diet. We must forbid the use of all things, which may either relax, dilate, or break the proceſſe of the *Peritonæum*, of which I have already treated sufficiently. Sometimes, but especially in old men, the guts cannot be restored into their place, by reason of the quantity of the excrements hardned in them: In this case they must not be too violently forced, but the patient must be kept in his bed, and lying with this head low, and his knees higher up; let the following Cataplasmes be applied.

Another

Another Figure of a man having a Rupture on both sides, shewing by what means, what kind of Trusse; and what shoulder-band he must be bound on each groin.

- A. Sheweth the shoulder-band divided in the midst for the putting through of the head.
 B. The Truss, with two bolsters, between which is a hole for putting through the yard. The form of both bolsters ought to be the same with the former.

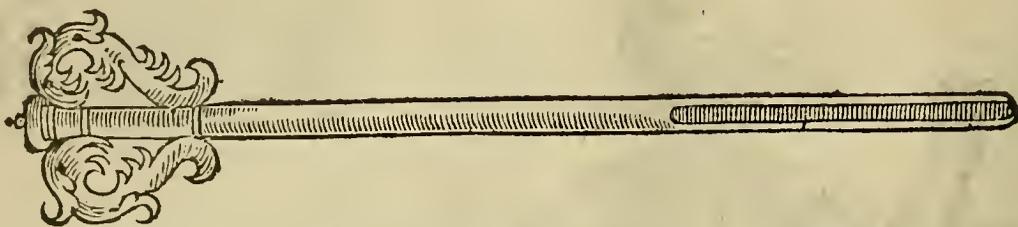

R rad. alb. & lil. ana ℥ij. seminis lini & sanagr. an. ℥β. fol. malva, viol. & pariet. an. m. β. Let them be boiled in fair water, afterwards beaten, and drawn through a searse, adding thereto of new butter without salt, and oil of Lillies, as much as shall suffice. Make a cataplasme in the form of a liquid pultis. Let it be applied hot to the cod, and bottome of the belly; by the help of this remedy when it had been applied all night, the guts have not seldome been seen of themselves, without the hand of a Chirurgeon, to have returned into their proper place. The windiness being resolved, which hindered the going back of the excrements into another gut, whereby they might be evacuated and expelled. But if the excrements will not goe back thus, the flatulencies, yet resisting and undiscussed, an emollient and carminative clyster is to be admitted, with a little Chymicall oyl of Turpentine, Dill, Juniper or Fennill. Clysters of Muscadine, oyl of Wallnuts, and *Aqua vite*, and a small quantity of any the aforesaid oyls, are good for the same purpose.

A Cataplasme to soften the excrements;

Chymicall oyl;

It often happens that the guts cannot yet be restored, because the proceſs of the *Peritoneum* is not wide enough. For when the excrements are fallen down with the gut into the cod; they grow hard by little and little, and encrease by the access of flatulencies caused by resolution, which cause such a tumor as cannot be put up through that hole, by which a little before it fell down: whereby it happens that by putrefaction of the matter there contained, come inflammations, and a new access of pain; and lastly, a vomiting and evacuation of the excrements by the mouth being hindered from the other passage of the fundament. They vulgarly call this affect *Miserere mei*. That you may help this symptome, you must rather assay extreme remedies, than suffer the patient to die by so filthy and loathsom a death. And we must cure it by Chirurgery after this manner following. We wil bind the patient lying on his back, upon a table or bench; then presently make an incision in the upper part of the cod, not touching the substance of the guts; then we must have a silver Cane, or Pipe, of the hickness of a Goose quill, round, and gibbous in one part thereof, but somewhat hollowed in the other, as is shewed by this following Figure.

The Figure of the Pipe or Cane.

We must put it into the place of the incision, and put it under the production of the *Peritonæum* being cut together with the cod, all the length of the production, that so with a sharp knife we may divide the process of the *Peritonæum*, according to that cavity separated from the guts there contained, by the benefit of the Cane in a right line not hurting the guts. When you have made an indifferent incision, the guts must gently be put up into the belly with your fingers, and then so much of the cut *Peritonæum* must be sowed up, as shall seem sufficient, that by that passage made more strait, nothing may fall into the cod after it is cicatrized.

But if there be such abundance of excrements hardened, either by the stay or heat of inflammation, that that incision is not sufficient to force the excrements into their place, the incision must be made longer, your Cane being thrust up towards the belly: so that it may be sufficient for the free regress of the guts into the belly. Then sow it up as is fit, and the way will be shut up against the falling down of the gut or käll; the process of the *Peritonæum* being made more strait, by reason of the future; for the rest, the wound shall be cured according to Art. But before you undertake this work, consider diligently whether the strength of the Patient be sufficient, neither attempt any thing before you have foretold, and declared the danger to the Patients friends.

CHAP. XVI.

Of the golden Ligature, or the *Punctus Aureus*, as they call it.

The Chirurgi-
call cure by
the golden Tie.

IF the Rupture will not be cured by all these means, by reason of the great solution of the continuity of the relax'd or broken *Peritonæum*, and the patient by the consent of his friends there present, is ready to undergoe the danger in hope of recovery; the cure shall be attempted by that which they call the *Punctus Aureus*, or Golden tie.

For which purpose a Chirurgion which hath a skilful and sure hand, is to be employed. He shall make an incision about the share bone, into which he shall thrust a Probe like to the Cane, a little before described; and thrust it long wayes under the process of the *Peritonæum*, and by lifting it up, separate it from the adjoining fibrous, and nervous bodies, to which it adheres; then presently draw aside the spermatick vessels, with the *Cremaster*, or hanging muscle of the testicle; which being done, he shall draw aside the proceffe it self, alone by it self: And he shall take as much thereof, as is too lax, with small and gentle mullets, perforated in the midst, and shal with a needle, having five or six threds, thrust it through as neer as he can to the spermatick vessels, and *Cremaster* muscles. But the needle also must bee drawn again in to the midst of the remnant of the process, taking up with it the lips of the wound; then the thred must be tied on a strait knot, and so much thereof must be left after the section, as may be sufficient to hang out of the wound. This thred will of it self be dissolved by little and little by putrefaction: neither must it be drawn out before that nature shall regenerate and restore flesh into the place of the ligature, otherwise all our labour shall be spent in vain.

And lastly, let the wound be clenfed, filled with flesh, and cicatrized, whose callous hardness may withstand the falling of the gut or käll.

Another man-
ner thereof.

There are some Chirurgions who would perform this golden ligature after another manner. They cut the skin above the share bone where the falling down commonly is, even to the process of the *Peritonæum*, and they wrap once or twice about it, being uncovered, a small golden wire, and only straiten the passage as much as may suffice to amend the looseness of this process, leaving the spermatick vessels at liberty; then they twist the ends of the wire twice or thrice with small mullets, and cut off the remnant thereof; that which remains after the cutting, they turn in, lest with the sharpness it should prick the flesh growing upon it. Then leaving the golden wire there, they cure the wound like to other simple wounds, and they keep the patient some fifteen or twenty daies in his bed, with his knees something higher, and his head something lower.

Many are healed by this means; others have fallen again into the disease by reason of the ill twisting of the wire.

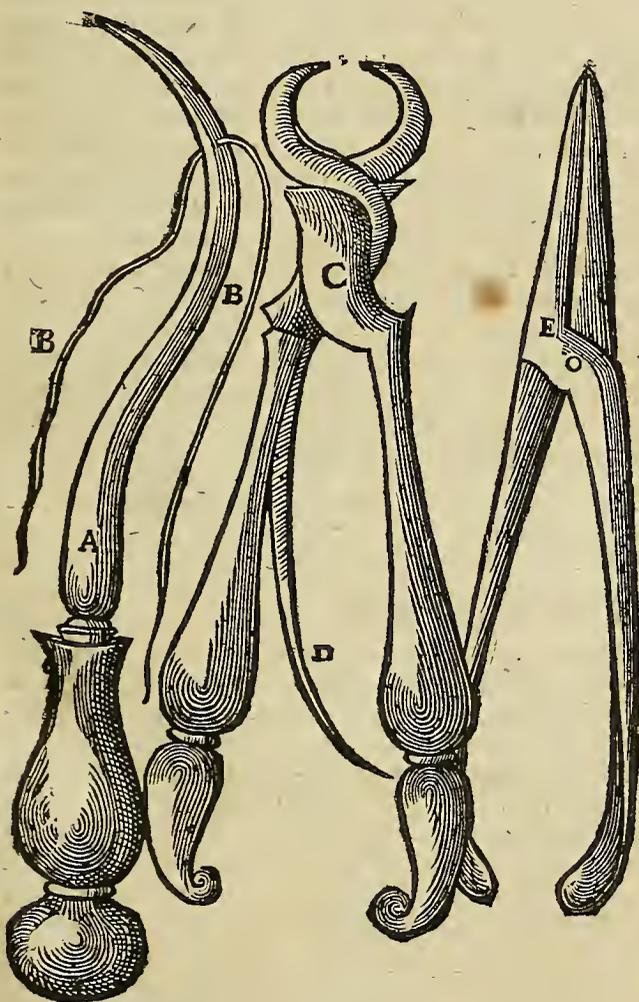

There

There is also another manner of this golden tie, which I judge more quick and safe, even for that there is no externall body left in that part after the cure. Wherefore they wrap a leaden wire in stead of the golden, which comes but once about the process of the *Peritonæum*; then they twine it as much as need requires; that is, not too loosly, lest it should leave way for the falling down of the body, neither too straitly, lest a Gangrene should come by hindring the passage of the spirits and nourishment. The ends thereof are suffered to hang out; when in process of time, this contraction of the *Peritonæum* seems callous, then the wire is untwisted and gently drawn out. And the rest of the cure performed according to Art. But let not the Chirurgeon thrust himself upon his work rashly, without the advice of the Physitian, for it diverse times comes to pass, that the testicles are not as yet fallen down into the cod by the too great sluggishness of nature, in some of a pretty growth, but remains long in the groins, causing a tumor with pain, which thing may make a good Chirurgeon believe that it is an *Enterocæle*. Therefore whilst he labors by repelling medicines and trusses to force back this tumor, he encrease the pain, and hinders the falling down of the testicles into the cod. I observed this not long agoe in a Boy, which an unskilful Chirurgeon had long, and grievously troubled, as if he had had a rupture: for when I had observed that there was but one stone in the cod, and knew the boy was never gelt, I bid them cast away the plaisters and trusses, and wisht his parents that they should suffer him to run and leap, that so the idling stone might be drawn into the cod, which thing by little and little, and without pain, had the event, as I foretold.

The third manner thereof.

A thing to be noted.

A History.

A. Shewes a crooked needle, having an eye not far from the point, through which you may put the golden wire.

B. B. The golden wire put through the eye of the needle.

C. The mullets or Pincers, to cut away the wast or superfluous ends of the wire.

D. The spring of the mullets.

E. The mullets to twist the ends of the wire together.

That the reason of this affect may be understood, we must know a man differs from a woman, only in efficacy of heat; but it is the nature of strong heat to drive forth, as of cold to keep in. Hence it is that the stones in men hang forth in the cod, but in women they lie hid in the lower belly. Therefore it happens that in some males more cold by nature, the testicles are shut up some certain time, untill at length they are forc't down into the cod by youthfull heat. But that we may return to our former treatise of the cod, although that way of curing ruptures wants not pain and danger, yet it is safer than that which is performed by gelding, which by the cruelty thereof exposes the patient to manifest danger of death. For the gelders whilst they fear lest when the cure is finished, the relaxation may remain, pull with violence the process of the *Peritonæum* from the parts to which it adheres,

adheres, and together with it a nerve of the sixth conjugation which runs to the stones; they offer the same violence to the spermatick vessels; by which things ensue great pain, convulsion, efflux of blood, inflammation, putrefaction, and lastly, death, as I have observed in many whom I have dissected, having died a few daies after their gelding. Although some escape these dangers, yet they are deprived of the faculty of generation for all their life after, for performance whereof, nature hath bestowed the testicles, as parts principally necessary for the conservation of mankind. Through which occasion *Galen* hath not feared to prefer them before the heart; because the heart is the beginning of life, but the testicles of a better life; for it is far more noble to live well, than simply and absolutely to live; therefore Eunuches degenerate into a womanish nature, for they remain without beards, their voice is weak, their courage fails them, and they turn cowards; and seeing they are unfit for all humane actions, their life cannot but be miserable. Wherefore I will never subscribe to the cutting out of the stones, unless a *Sarcocele* or Gangrene invade them. But that the way of performing the *Punctus aureus* may be better known, I have thought good here to set the instruments, by which this operation is performed, before your view.

Lib. de arte
medica.

Lib. de sem.

Another more easie and safe way to restore the gut and kall.

Lib. 3. cap. 33.

Theodorick and Guido have invented another way of performing this operation. They put back into their places the gut and kall being fallen down, the patient being so placed, that his thighs are high and his head is somewhat low; then they draw aside the lower portion of the production of the *Peritonæum*, and also the spermatick vessels, and cremaster muscle to the *Ischium*; then by applying a caustick fitted to the age and disease, they burn the other part of the process, directly perpendicular to the share bone, where the gut did fall down. Then they pull off the eschar thus made with a knife even to the quick, then they apply another caustick in the same place, which may go even to the bone, then procure the falling of this eschar made on the foresaid process. And afterwards they heal the ulcer which remains, which presently contracting somewhat a thick *Callus*, so keeps up the guts and kall, that it binds them from falling down into the cod. This way of restoring the gut and kall, though it be safer and more facile; yet the Chirurgeon must not attempt it, if the guts or kall stick so fast, agglutinated to the process of the *Peritonæum*, that they cannot be severed, nor put back into their places (for from the guts so burnt and violated, greater mischief would ensue) if by the broken and too much dilated process, the bodies thereby restrained, make an exceeding great tumor by their falling down; if the testicle yet lying in the groin as in a *Bubonocoele*, a kind of *Enterocoele*, being not yet descended into the *Scrotum* or cod; if the patients be not come to such age as they can keep themselves from stirring, or hold their excrements whiles the operation is performed.

CHAP. XVIII.

Of the cure of other kinds of Ruptures.

Hydrocele is the falling down of the kall into the groin, or cod, it hath the same causes as an *Enterocoele*. The signs have been explained. It is not so dangerous, nor infers a consequence of so many cvill symptomes, as the *Enterocoele* doth, yet the cure is the same with the other.

Hydrocele is a waterish tumor in the cod; which is gathered by little and little between the membranes encompassing the testicles, especially the *Dartes & Erythroides*; it may be called a particular dropsie, for it proceeds from the same causes, but chiefly from the defect of native heat. The signs are a tumor encreasing slowly without much pain, heavy, and almost of a glassie clearness, which you may perceive by holding a candle on the other side, by pressing the cod above, the water flows down, and by pressing it below, it rises upwards, unless peradventure in too great a quantity it fills up the whole capacity of the cod, yet it can never be forced or put up into the belly as the kall or guts may, for oft-times it is contained in a cyst or bag; it is distinguished from a *Sarcocele*, by the smoothness and equality thereof. The cure must first be tried with resolving, drying and discussing medicines, repeated often before, and in the Chapter of the dropsie; this which folowes I have often tried and with good success.

R *Vng. comitissæ, & desiccatur. rub. an. ʒij. malaxentur simul*, and make a medicine for your ease. The water by this kind of remedy is digested and resolved, or rather dried up, especially if it be not in too great quantity. But if the swelling, by reason of the great quantity of water, will not yeeld to those remedies, there is need of Chirurgery; the cod and membranes wherein the water is contained, must be thrust through with a Seton, that is, with a large three-square pointed needle, thred with a skean of silk; you must thrust your needle presently through the holes of the mullets made for that purpose, not touching the substance of the Testicles. The skean of thred must be left there, or removed twice

ter.

or thrice a day, that the humor may drop down, and be evacuated by little and little. But if the pain be more vehement by reason of the Seton, and inflammation come upon it, it must be taken away, and neglecting the proper cure of the disease, we must resist the symptoms.

Some Practitioners use not a Seton, but with a Razor, or incision knife, they open the lower part of the cod, making an incision some half fingers breadth long, penetrating even to the contained water; alwaies leaving untouched the substance of the testicles and vessels, and they keep the wound open, untill all the water seems evacuated; truly by this only way the cure of a watery rupture whose matter is contained in a cyst, is safe, and to be expected; as we have said in our Treatise of Tumors in generall.

The *Pneumatocele*, is a flatulent tumor in the cod, generated by the imbecillity of heat residing in the part.

It is known by the roundness, lenity, renitency and shining. It is cured by prescribing a convenient diet, by the application of medicines which resolve and discusse flatulencies, as the seeds of Annis, Fennell, Fænugreek, *Agnus Castus*, Rue, *Origanum*, other things set down by *Avicen* in his Treatise of Ruptures. I have often used with good success for this purpose, *Emplastrum Vigonis cum Mercurio*; and *Emplastrum Diacaltheos*, dissolved in some good wine, as Muscadine, with oyl of Bayes.

A *Sarcocele* is a tumor against nature, which is generated about the stones by a scirrhous flesh. Grosse and viscid humors breed such kind of flesh, which the part could not overcome and assimilate to it self; whence this over-abundance of flesh proceeds like as Warts do. *Varices*, or swollen veins often associate this tumor; and it increases with pain. It is known by the hardness, asperity, inequality, and roughness. It cannot be cured but by amputation or cutting it away; but you must diligently observe, that the flesh be not grown too high, and have already seized upon the groin, for so nothing can be attempted without the danger of life.

But if any may think, that he in such a case may somewhat ease the patient by the cutting away of some portion of this same soft flesh, he is deceived. For a *Fungus* will grow, if the least portion thereof be but left, being an evil cure worse than the former; but if the tumor be either small or indifferent, the Chirurgion taking the whole tumor, that is, the testicle tumified through the whole substance, with the process encompassing it, and adhering thereto on every side, and make an incision in the cod, even to the tumor; then separate all the tumid body, that is, the testicle from the cod; then let him thrust a needle with a strong thred in it, through the midst of the process, above the region of the swollen testicle; and then presently let him thrust it the second time through the same part of the process; then shall both the ends of the thred be tied on a knot, the other middle portion of the *Peritonæum* being comprehended in the same knot. This being done, he must cut away the whole process with the testicle comprehended therein. But the ends of the thred, with which the upper part of the process was bound, must be suffered to hang some length out of the wound, or incision of the cod. Then a repercussive medicine shall be applied to the wound, and the neighbouring parts with a convenient ligature. And the cure must be performed as we have formerly mentioned.

The *Cirsocele* is a tumor of veins dilated, and woven with a various and mutuall implication about the testicle and cod, and swelling with a grosse and melancholy blood. The causes are the same as those of the *Varices*. But the signs are manifest.

To heal this tumor, you must make an incision in the cod, the breadth of two fingers to the *Varix*. Then you must put under the varicous vein, a needle having a double thred in it, as high as you can, that you may bind the roots thereof: then let the needle be again put after the same manner about the lower part of the same vein, leaving the space of two fingers between the ligatures. But before you bind the thred of this lowest ligature, the *Varix* must be opened in the midst, almost after the same manner as you open a vein in the arm to let blood: That so this grosse blood causing a tumor in the cod, may be evacuated as is usually done in the cure of the *varices*. The wound that remains shall be cured by the rules of Art after the manner of other wounds: Leaving the threds in it, which presently fall away of themselves. To conclude then, it being grown callous, especially in the upper part thereof, where the vein was bound, it must be cicatrized, for so afterwards the blood cannot be strained or run that way.

Hernia Humor alis is a tumor generated by the confused mixture of many humors in the cod, or between the tunicles which involve the testicles, often also in the proper substance of the testicles. It hath like causes, signs and cure as other tumors. While the cure is in hand, rest, trusses, and fit rowlers to sustain and bear up the testicles, are to be used.

CHAP. XVIII.

Of the falling down of the Fundament.

The causes.

When the muscle called the *Sphincter* which ingirts the Fundament is relaxed, then it comes to passe that it cannot sustain the right gut. This disease is very frequent to Children by reason of the too much humidity of the belly; which falling down upon that muscle mollifieth and relaxeth it or presseth it down by an unaccustomed weight, so that the muscles called *Levatores Ani*, or the lifters up of the Fundament, are not sufficient to bear up any longer. A great bloody flux gives occasion to this effect. A strong endeavour to expell hard excrements, the *Hæmorrhoids*, which suppressed do over-load the right gut, but flowing relax it: Cold, as in those which go without breeches in winter, or sit a long time upon a cold stone, a stroak or fall upon the holy-bone, a palsie of nerves which go from the Holy-bone to the muscles the lifters up of the fundament: the weight of the stone being in the bladder.

The cure.

That this disease may be healed, we must forbid the Patient too much drinking, too often eating of broth, and from feeding on cold fruits. For locall medicines the part must be fomented with an astringent decoction made of the rinds of Pomegranats, galls, myrtles, knotgrasse, shepherds purse, cypress nuts, alum, and common salt boiled in smiths water or red wine. After the fomentation, let the gut be anointed with oyl of Roses or myrtles, and then let it be gently put by little and little into its place, charging the child if he can understand your meaning, to hold his breath. When the gut shall be restored, the part must be diligently wiped lest the gut fall down again by reason of the slipperiness of the uncti-on. Then let the powder prescribed for the falling down of the womb be put into the fundament as far as you can: Then you must straitly bind the loins with a swath, to the midst whereof behind let another be fastned which may be tied at the *Pubes* coming along the *Perineum*, so to hold up the fundament; the better to contain it in its place, a sponge dipt in the astringent decoction. The patient if he be of sufficient age to have care of himself, shall be wished when he goes to stool that he sit upon two pieces of wood being set some inch a sunder, lest by his straining he thrust forth the gut together with the excrement; but if he can do it standing, he shall never by straining thrust forth the gut.

Hippocrates his cure.

But if the gut cannot by the prescribed means be restored to its place, *Hippocrates* bids that the Patient hanging by the heels be shaken, for so the gut by that shaking will return to his place: but the same *Hippocrates* wisheth to anoint the fundament, because that remedy having a drying faculty, hath also power to resolve the flatulent humors without any acrimony, by reason of which the gut was the less able to be contained in his place.

CHAP. XIX.

Of the Paronychia.

What the Paronychia is.

The *Paronychia* or *Panaris* is a tumor in the ends of the fingers, with great inflammation, coming of a malign and venomous humor, which from the bones, by the *Periosteum* is communicated to the tendons and nerves of that part which it affecteth, whereof cruell symptoms do follow, as pulsi-que pain, a fever, restlessness, so that the affected through impatience of the pain are variously agitated like those tormented with Carbuncles: for which cause *Guido* and *Johannes de Vigo* judge this disease to be mortall; wherefore you must provide a skilfull Physitian for the cure of this disease, which may appoint convenient diet, purging and blood-letting. In the mean time the Chirurgeon shall make way for the virulent and venenate matter, by making incision in the inner part of the finger, even to the bone alongst the first joint thereof; for *Vigo* saith there is not a presenter remedy, if so be that it be quickly done and before the maturation of the matter; for it vindicates the finger from the corruption of the bone and nerves, and asswages pain, which I have often and happily tried immediately at the beginning, before the perfect impression of the virulencie.

Lib. cap. 4. tract.

But the wound being made you must suffer it to bleed well, then presently let him dip his finger in strong and warm vinegar, in which some treacle being dissolved may draw forth the virulencie. But to appease the pain, the same remedies must be applyed to the affected part as are used in Carbuncles, as the leaves of Sorrell, Henbane, Hemlock, Mandrake roasted under the Embers and beaten in a Morter with new *Vnguentum Populeon*, or oyl of Roses or new butter without salt: for such like medicines also helpe forward suppuration: whilst by their coldness, they repress the extraneous heat affecting the part; and so strengthen the native heat being the author of suppuration: which reason moved the ancient Physitians to use such medicines in a Carbuncle: but if by reason of the fearfulness of the patient, or unskilfulness of the Chirurgeon,

no incision being made, a Gangren and Sphacel shall possess the part, it remains that you cut off with your cutting mullets as much of the part as shall be corrupt, and perform the rest of the cure according to Art. Yet it doth not seldome happen that there may be no need to cut off such a finger, because it being corrupted together with the bone by little and little dissolve into a purulent or rather sanious or much stinking filth. But in this affect there is often caused an Eschar by the aduision of putredinous heat, and superfluous flesh indued with most exquisite sense groweth underneath it, which must in like manner be cut off with the Mullets that the part may receive comfort, the pain being asswaged by the copious effusion of blood.

CHAP. XX.

Of the swelling of the Knees.

After long and dangerous diseases there oftentimes arise Tumors in the knees, and also in Plethorick bodies and such as have evill juyce after labours and exercise. This kind of disease is frequent because the humor easily falls into the part which hath been heated by labour. But if such tumors follow long diseases, they are dangerous and difficult to cure, and therefore not to be neglected, for bitter pain accompanieth them, because the humor falling thither distends the Membranes, which being many involve the part; besides that this humor participateth of a certain virulent and maligna quality whether it be cold or hot, when it hath settled into those parts, being such as we find in the pains of the joynts, and in the bitings of venomous creatures.

For the cure if the tumor be caused by blood, let a slender and a refrigerating diet be appointed, and phlebotomy for the revulsion of the antecedent cause; divers locall medicines shall be used according to the variety of the four times. But for to asswage the pain, *Anodyne*, or mitigating medicines shall be appointed: of all which we have sufficiently treated in the Chapter of the cure of a Phlegmon.

And because these parts are of exact sense, if there be necessity to open the tumor, yet must we not do it rashly or unconsiderately, for fear of pain and evill accidents.

This kind of tumor is oft-times raised by wind contained there; in which case the Chirurgion must be very provident, that he be not deceived with the shew of flowing of the humor, which he seems to perceive by the pressure of his fingers, as if there were matter and humor contained therein, and so be brought to open the tumor. For the wind breaking forth in stead of the humor, causeth evill symptoms by reason of the section rashly made in a part so sensible.

But if waterish humors shall tumefie the part, the body shall first be purged with medicines purging flegm: And then inciding, attenuating, rarifying, discussing and very drying locall medicines shall be used.

Of which we have abundantly spoken in the Chapter of the *Oedema*. Yet this humor divers times lyes deep between the whirl bone and the joint, which causeth it that it can be discussed and resolved by reason of the weakness of the part and defect of heat, so that the adventitious humor often moves and excludes the bones from their seat. As I have observed it to have happened to many.

In which cause Irrigations of red wine falling something high, whereby the force of the medicine may enter and more easily penetrate, are much commended.

CHAP. XXI.

Of the Dracunculus.

No man can chuse, but explain in this place those things which may be spoken of that kind of tumor against nature, which by the ancients is called *Dracunculus*. The matter & reason of these hath been variously handled by divers Authors, so that hitherto we have nothing written of them to which we may by right and with good reason adhere as a firm foundation of their essence.

For first, for *Galens* opinion, *Lib. 6. de Loc. affect. cap. 3.* The generation, saith he, of those hairs which are evacuated by the urine is worthy no less admiration than the *Dracunculi*, which as they say, in a certain place of *Arabia* breed in the legs of men being of a nervous nature and like worms in colour and thickness.

Therefore seeing I have heard many who have said they have seen them, but I my self never saw them, I cannot conjecture any thing exactly neither of their originall nor essence.

Paulus Aegineta writes that the *Dracunculi* are bred in *India*, and the higher parts of *Aegypt*, like worms in the musculous parts of mans body, that is, the arms, thighs, and legs, and also creep by the intercostall muscles in children with a manifest motion.

But whether they be creatures indeed, or only have the shape of creatures, they must be cured with a hot fomentation, by which the *Dracunculus* raised to a just tumor, may put forth it self, and be pluckt away peece-meal with the fingers: also suppurating Cataplasms

may be applyed, composed of water, hony, wheat and barley meal.

Cap. 21. lib. 4.
sent. 3. tract. 3.

Avicen being various, having no certainty whereon to rest, inclineth one while to this, and another while to that opinion: for now he speaketh of the *Dracunculi* as of creatures, then presently of a matter and humor shut up in a certain place; for the rest he rightly delivers the cure and essence of this disease, as we shall afterwards shew.

Lib. 14. cap. ult.

Aetius saith, the *Dracunculi* are like worms, and that they are found sometimes great, sometimes small, and that their generation is not unlike to that of flat worms, which are bred in the guts, for they move under the skin, without any trouble, but in process of time, the place becomes suppurate about the end of the *Dracunculus*. The skin openeth, and the head thereof is thrust forth.

The Cure out
of *Aetius*.

But if the *Dracunculus* be pulled it causeth great grief; especially if it be broken by too violent pulling. For that which is left causeth most vehement pain. Wherefore that the creature may not run back, the arm must be bound with a strong thred, and this must be done every day, that the *Dracunculus* going forward by little and little, may be intercepted by this binding, but not broken off.

The place must be bathed with *Aqua Mulsa* and oyl in which wormwood or southernwood hath been boyled, or some other of those medicines which are prescribed for the worms of the belly.

But if the *Dracunculus* going forward of its one accord, may be easily drawn forth, we must do nothing else: but if it be turned to suppuration we must not leave off the Cataplasms, the *Aqua Mulsa* and anointing with oyl: It was usuall with him after the taking away of the Cataplasms, to apply *Emplastrum e Baccis Lauri*: but when it is come to suppuration the skin must be opened long wayes, and the *Dracunculus* so laid open must be taken away, but the skin must be filled with lint, and the rest of the suppurative cure used, so that the creature being suppurated and drawn forth, the wound may be incarnated and cicatrized.

Tractat. 7.
cap. 34.
The cure out of
Rhasis.

Rhasis writeth, that when the part is lifted up into a blister, and the vein hastneth its egress, it is good for the Patient to drink the first day half a dram of *Aloes*, the next day a whole dram, the third day two drams; and in like manner the place affected must be fomented with *Aloes*, for so that which lies hid will break forth: that which shall come forth must be rolled in a pipe of lead, which may equal the weight of a dram so that it may hang down, for the vein drawn by the weight will come more forth; and when that which shall come forth is grown much and long, it must be cut off, but not by the root, but so that a portion thereof may remain and hang forth, to which the leaden pipe may be fastened, for otherwise it would withdraw it self into its skin and its lurking hole, and so cause a putrid and malign ulcer.

Therefore we must gently meet with this disease, and the vein must be drawn by little and little out of the body untill it be all come forth that no worse thing happen: but if by chance it shall happen that as much of the vein as shall be come forth shall be cut off by the roots, then the Ulcer must be opened long wayes with an incision knife, and that so that whatsoever remains thereof may be wholly taken away. Then for some dayes the part must be anointed with butter untill whatsoever of such a substance adheres, being consumed with putrefaction shall flow away. Then the Ulcer must be cured with sarcotick things.

His opinion of
them.

Therefore *Rhasis* thus in the same text expresseth the same thing by divers names, and armed with Iron and Lead, he comes to the cure thereof, as if he meant to encounter with some fierce beast.

Soranus his o-
pinion.

Soranus the Physitian, who lived in the times of *Galen*, was of a quite contrary opinion, as *Paulus Aegineta* in the place being before cited, relates of him; as who denies the *Dracunculus* to be a living creature, but only a condensation of a certain small nerve, which seems both to the Physitians and Patients to have some motion under the skin.

Wherefore *Soranus* seems to have come neerer the truth than the rest, but yet not so, as thoroughly to understand, and know the essence of this disease, as we shall demonstrate hereafter.

Epist. 2. lib. 7.

Manardus writes, that the *Dracunculi* are generated of evill and unlaudable blood, gross, hot, and melancholick, or of adust phlegm very much dried.

Gorræus a most learned Physitian of our time, *Lib. de Definitionib. medic.* denies any of our Physitians to be able to say any thing of the *Dracunculi*, because it is a disease so unfrequent in these our regions, that it is scarce ever met withall in practice.

The Author of the Introduction, and Medicinall definitions, defines the *Dracunculus* to be a disease very like the *Varices*; then causing great pain, when increasing by little, and little, it begins to be moved: Therefore to be cured after the same manner, and by the same method of Section and incision, as the *Varices* are. Which thing chiefly seems to have moved *Guido* to refer this kind of disease to the *Varices* in his Tractate of Impostumes, because it hath the same cause, and is healed with the same remedy as the *Varices*.

But seeing that divers names have been imposed upon this disease by severall writers, yet they have all expressed it by the name of a vein, for it is called by *Avicen* and *Guido*, *Vena Meden*, because it is a disease frequent in the City *Medina*: by *Albucaasis*, *vena civilis*. *Haliabas* hath

hath called it *vena famosa*; others have called it *Vena Cruris* or the leg vein. Truly the contrariety of so many opinions repugnant not only amongst themselves, but also with themselves, easily argueth how little certainty they had of the essence of this disease, who have written of it unto us: To which also this may be added, that none of the latter Physicians have written any things thereof. For although *Jacobus Dalechampius* a man most conversant in every part of Physick, hath written much of this matter in his book of the French Surgery which he set forth some years ago: Yet he hath left us no amplier testimony of his industry, than that he was very diligent in collecting the writings of the Ancients concerning this thing, interposing no judgment of his own, the better to assure us of a thing so controverted.

But my modesty cannot so contain me, but that I shall chuse rather to undergoe the censure of being thought too daring, than (as much as in me lyeth) to suffer this question of the *Dracunculi* to remain longer ambiguous and undecided. Therefore for the present, I will thus order it, that refuting the opinions of the Ancients I may strengthen by certain reasons, my opinion of the essence and cure of this disease.

For first, that *Dracunculi* are no living things, nor like unto worms, nor of like generation as the flat worms of the belly, which was the opinion of *Aetius*, is easie to disprove both by his writings, as also by reason it self. For he writes that the broad worm which he calls *Tenia*, is as it were a certain *Metamorphosis* or transmutation of the inner tunicle of the small guts into a quick living and movable body.

But no man ever said, neither will he confess that the *Dracunculi* hath the materiall causes of their beginning from the Tunicle of the vein, in which they are closed, or from the fibers of a nervous body, to which often they are adjoined; but much less from the skin under which they lye, may they draw their materiall causes of their originall.

Moreover, neither can there be any generation of worms, nor of any other living creatures whatsoever, who have their originall from putrefaction, unless by the Corruption of some matter, of whose better and more benign part, nature by the force of the vitall heat, produceth some animate body, as *Aristotle* teacheth. Wherefore to produce this effect, it is fit the matter should have such a disposition to putrefaction as is required for the generation of such a creature as they would make the *Dracunculus* to be: It is fit the helping causes should coucur as assistants to the principals in the action. And it is meet the place should be opportune or fit.

But there may be many causes found which may give life to the *Dracunculi*, for by the common consent of all those who have written of them, their generation proceeds from an humor melancholick, terrestriall and gross, which by its qualities both by the first coldness and dryness, as also by the second, that is Acidity, is not only thought most unfit of all others for putrefaction, but also is judged to resist putrefaction, as that which is caused by heat and superfluous heat humidity. Besides if the materiall cause of this disease should be from an humor putrefying and turning by putrefaction into some living creature, it was fit there should be stench also, as being an unseparable accident of putrefaction, for thus the excrements in the guts of which the worms are generated, do smell or stink.

Therefore that which exhales from their bodies which are troubled with the *Dracunculi*, should be stinking, as it happens to those sick of the *Pthiriasis* or *Lowse-evill*. But none of those who have delivered the accidents or symptomes of the *Dracunculi* are found to have made mention hereof. But for the efficient cause whereby so great heat may be raised in the places next under the skin, by the efficacy whereof such a creature may be formed of a matter melancholick and most unapt to putrefie, as they make the *Dracunculus* to be who faine our bodies to be fruitfull monsters; especially seeing the surface of the body is continually ventilated by the small Arteries spread under the skin, as also by the benefit of insensible transpiration, and breathed with the coolness of the air incompassing us. But now the materiall and efficient causes being defective, or certainly very weak, for the generation of so laborious an effect; what coadjutory cause can yeeld assistance? Can the humidity of meats? for those bodies which are fed with warm and moist meats, as milk, Cheese, Summer fruits, usually breed worms, as we are taught by experience in children.

But on the contrary *Avicen* in the place before cited writeth, that meats of a hot and dry temper chiefly breed this kind of disease, and that it is not so frequent to moist bodies and such as are accustomed to the Bath, moist meats and wine moderately taken. But whether may the condition of the air of those regions in which it is as it were, an Endemiall disease, confer any thing to the generation of such creatures? Certainly for this purpose a cloudy, warm and thick air, such as useth to be at the beginning of the Spring when all the places resound with frogs, toads and the like creatures breed of putrefaction.

But on the contrary *Jacobus Dalechampius* by the opinion of all the Physicians that have written of the *Dracunculi*, writes that this disease breeds in the dry and Sun burnt regions of *India* and *Arabia*; but if at the least that part of our body which is next under the skin should have any opportunity to ingender and nourish such creatures, they may be judged to have written that the *Dracunculus* is a living creature with some probability. But if there be no opportunity for generation in that place, nor capacity for the nourishment of such like

creatures as in the guts, if that region of the body be breathed upon with no warmth and smothering heat, if it be defiled with none of those gross excrements, as the guts usually are, but only by the subtiler exhalation, which have an easie and insensible transpiration by the pores of the skin, which may seem to be a just cause of so monstrous and prodigious an effect: but we shall little profit with these engines of reason unless we cast down at once all the Bulwarkes, with which this old opinion of the *Dracunculi* may stand and be defended.

For first they say, why have the ancients expressed this kind of disease by the name of a living thing, that is, of a *Dracunculus* or little Serpent? I answer, because in Physick names are often imposed upon diseases rather by similitude than from the truth of the thing; for the confirmation whereof, the examples of three diseases may suffice, that of the *Cancer*, *Polypus*, and *Elephas*. For these have those names not because any Crab, *Polypus*, or living Elephant may breed in the Body by such like diseases, but because this by its propagation into the adjacent parts represents the feet and claws of a Crab; the other represents the flesh of the Sea-*Polypus* in its substance; and the third because such as have the Leprosie have their skin wrinckled, rough, and horrid with scales and knots, as the skin of a living Elephant. So truly this disease of which we now enquire seems by good right to have deserved the name *Dracunculus*, because in its whole conformation, colour, quality and production into length and thickness it expresseth the image of a Serpent. But whence, will they say, (if it be without life) is that manifest motion in the matter? We reply that the humor the cause of this disease is subtil and hot, and so runs with violence into the part whence it may seem to move. But when the *Dracunculi* are separated, why do they put their heads as it were out of their holes? We answer, in this the Ancients have been very much deceived, because after the suppuration the ulcer being opened, some nervous body being laid bare, thrust forth and subjected it self to the sight, which by the convulsive and shaking motion might expresse the crooked creeping of a Serpent. But they will say, pain happens not unless to things indued with sense & life, but this *Dracunculus* when he is drawn too violently, especially if he be broken, thereby will cause extream pain: We do answer, that the conclusion doth not follow & is of no consequence, for these pains happen not unless when the unprovident Surgeon draws or puls in stead of the *Dracunculus* some nervous or membranous body swollen and repleat with an adust humor, whence there cannot but be great pain that part being puld which is the author of sense. But it is childish to say that the *Dracunculus* feels, for that it causeth sharp pains to the living body in which it is. Therefore that at last we may determin something of the nature, essence and generation of these *Dracunculi*, I dare boldly affirm it is nothing else but a tumor and abscess bred from the heat of the blood in a venenate kind. Such blood driven by the expulsive faculty through the veins to the Externall parts, especially the limits, that is, the Arms and Legs, causeth a tumor round and long often stretched from the joynt of the shoulder even to the wrist, or from the groin even to one of the Ankles with tension, heat, renitency, pricking pain, and a fever. But this tumor is some while stretched forth streight, otherwhiles into oblique and crooked tumors, which hath been the cause that many taken with this kind of disease, and having their limbs so infolded as with the twinings of a Serpent, would say they had a Serpent. I have thus much to say of the *Dracunculi*, especially of those of our own country.

The Cure.

For the cure, it is not unlike to the cure of a Phlegmon arising from a defluxion, for here also in like manner the remedies must be varied according to the four times of the disease, and the same rule of diet, phlebotomy and purging must be observed, which is before prescribed in the cure of a Phlegmon.

The mention of the *Dracunculi* calls to my memory another kind of Abscess, altogether as rare. This our French men name *Cridones*, I think a *Crimibus*. i. from hayrs: it chiefly troubles children and pricks their backs like thorns. They toss up and down being not able to take any rest. This disease ariseth from small hairs which are scarce of a pins length, but those thick & strong. It is cured with a fomentation of water more than warm, after which you must presently apply an oyntment made of hony and wheaten flower; for so these hairs lying under the skin are allured and drawn forth; and being thus drawn, they must be plucked out with small mullets. I imagine this kind of disease was not known to the ancient Physicians.

So the *Malum pilare* in *Aristotle cap. 81. lib. 7. hist. animal.*

The End of the Eighth Book.

OF WOUNDS IN GENERALL.

THE NINTH BOOK.

CHAP. I.

What a wound is, what the kinds and differences thereof are, and from whence they may be drawn, or derived.

Wound is a solution of Continuity, caused by a stroak, fall, or bite, newly done, bloody and with putrefaction and filth. They also call it a new simple ulcer; for the solution of continuity happens to all parts of the body; but according to the diversity of parts, it hath divers names amongst the Greeks. For in the flesh it is called *Helcos*, in the bone *Catagma*, in the nerve *Spasma*, in the ligament *Thlasma*, in the vessels *Apospasma*, in the Muscles *Regma*; and that solution of continuity, which happens in the vessels, their mouths being open; is termed *Anastomasis*, that which happens by erosion, *Aneurosis*; that which is generated by sweating out and transcolation, *Diapedesis*. That these may be the more easily understood, I have thought good to describe them in the following table.

What a Wound properly is.

Divers appellations of wounds according to the varieties of the parts.

A Table of the differences of Wounds.

The differences of wounds are drawn or taken

From the nature of the parts in which they are made or happen. But these parts are

Either similar, and these,

Or Organical, and these either

- Either soft, as the
 - Glandules,
 - Flesh, Fat,
 - Marrow.
- Or hard, as
 - A Bone,
 - A Gristle.
- Or of a middle consistence, as the
 - Membranes,
 - Ligaments,
 - Fibers, Vessels,
 - Nerves, Veins,
 - Arteries.
- Principall, as the
 - Brain, Heart,
 - Liver, to which some add the Womb and Testicles.
- Or serving the principall, as
 - The Weason,
 - Lungs, gullet,
 - Stomach, Guts,
 - Bladder.
- Or neither
 - The Ears, Nose,
 - Feet, hands, and other of the same kind.

from

From their proper essence, from whence they are called,	Simple wounds Or compound,	When there is no complication of any other disease or symptome besides.
		When there is a complication of some one or more diseases, which unlesse they be taken away, wee must not hope for to cure the wound.
From their quantity according to which they are called,	Great, Indifferent, Little,	Long, Broad, Deep.
		Short, Narrow, Superficiary.
From their figure, according to which they are named,	Streight, Oblique, Cornered.	

CHAP. II.

Of the causes of Wounds.

Divers denominations from their causes.

ALL things which may outwardly assail the body with force and violence, may be counted the causes of wounds; which are called green, and properly bloody. These things are either animate, or inanimate. The animate, as the bitings, and prickings of beasts. The Inanimate, as the stroak of an arrow, sword, club, gun, stone, a dagger, and all such like things.

From the variety of such like causes, they have divers names: for those which are made by sharp and pricking things are called punctures: those caused by cutting things, are called wounds or gashes: and those which are made by heavy and obtuse things are named Contusions, or wounds with contusions.

CHAP. III.

Of the signs of Wounds.

A caution for making reports of Wounds.

Wounds are first known by sight, and by the signs drawn from thence. The Chirurgeon ought first and chiefly, to consider, what wounds are curable, and what not; what wounds will scarce admit of cure, and what may be easily cured; for it is not the part of a prudent Chirurgeon, to promise cure in a deadly or dangerous and difficult wound; lest he may seem to have killed him, whom not the insufficiency of the Art, but the greatnesse of the wound hath slain.

But when the wound is dangerous, but yet without despair of recovery, it belongs to him to admonish the Patients friends which are by, of the present danger, and doubtfull state of the wound, that if Art shall be overcome by the greatnesse thereof, he shall not be thought ignorant of the Art, neither to have deceived them.

A Jugling cheating Chirurgeon.

But as this is the part and duty of a good and prudent Chirurgeon, so it is the trick of a cheating and jugling knave, to enlarge small wounds, that so he may seem to have done a great cure, when it is nothing so.

But it is agreeable to reason, that the Chirurgeon professing the disease easie to be cured, will think himself in credit bound by such promises and his duty, and therefore seek all means for the quick recovery of the Patient; lest that which was of its own nature smal, may by his negligence become great. Therefore it is expedient, he should know what wounds are to be accounted great.

Lib. 4. Meth. cap. 6. 1.

Wounds are called great out of three respects,

This (as Galen saith) is three ways to be known; The first is by the magnitude and principality of the part affected; for thus the wounds of the Brain, Heart, and of the greater vessels, though small of themselves, yet are thought great. Then from the greatnesse of the solution of continuity; for which cause wounds may be judged great, in which much of the substance of the part is lost in every dimension, though the part be one of these which are accounted servile. Then from the malignity; through which occasion the wounds of the joints are accounted great, because for the most part, they are ill conditioned.

CHAP. IIII.

Of Prognosticks to be made in Wounds.

Those Wounds are thought dangerous, wherein any large nerve, vein, or Artery are hurt. From the first there is fear of convulsion, but from the other large effusion of the veinous, or arterious blood, whence the powers are debilitated; also these are judged evill, which art upon the arm pits, groins, lesks, joynts and between the fingers; and likewise those which hurt the head or tail of a Muscle. They are less dangerous of all other which wound only the fleshy substance. But they are deadly which are inflicted upon the Bladder, Brain, Heart, Liver, Lungs, Stomach and small guts. But if any Bone, Gristle, Nerve or portion of the cheek or prepuce, shall be cut away, they cannot be restored. Contused wounds are more difficult to cure, than those which are only from a simple solution of continuity; for before you must think to heal them up, you must suppurate and cleanse them; which cannot be done in a short time. Wounds which are round and circular are so much the worse; for there can be no unity unlesse by an angle, that is, a meeting together of two lines, which can have no place in round wounds, because a circular figure consists of one oblique line. Besides, wounds are by so much thought the greater, by how much their extremis and lips are the further disjoyned, which happens to round Wounds. Contrary to these are cornered wounds or such as are made alongst the fibers, as such as may be easily healed.

Wounds may be more easily healed in young men, than in old, because in them nature is more vigorous, and there is a greater plenty of fruitfull, or good blood, by which the losse of the flesh may be the better and more readily restored, which is slowlier done in an old body, by reason their blood is smaller in quantity and more dry, and the strength of nature more languid.

Wounds received in the Spring, are not altogether so difficult to heal as those taken in Winter or Summer. For all excess of heat and cold is hurtfull to them, it is ill for a convulsion to happen upon a Wound, for it is a sign that some Nervous body is hurt; the braine suffering together therewith, as that which is the originall of the Nerves. A Tumor coming upon great Wounds is good; for it shews the force of nature is able to expell that which is harmfull, and to ease the wounded part. The organicall parts wholly cut off cannot again be united: because a vitall part once severed and plucked from the trunk of the body cannot any more receive influence from the heart as from a root without which there can be no life. The loosened continuity of the Nerves, Veins, Arteries, and also the bones, is sometimes restored, not truly, and as they say, according to the first intention, but by the second, that is, by reposition of the like, but not of the same substance. The first intention takes place in the fleshy parts by converting the Alimentary blood into the proper substance of the wounded part. But the second, in the spermatique parts in which the lost substance may be repaired by interposition of some heterogeneous body, which nature, diligent for its own preservation, substitutes in place of that which is lost: for thus the body, which restores and agglutinates, is no bone but a *Callus*, whose originall matter is from an humor somewhat grosser than that, from whence the bones have their originall and beginning.

This humor, when it shall come to the place of the fracture, agglutinates the ends of the bones together, which otherwise could never be so knit by reason of their hardness. The bones of children are more easily and speedily united by reason of the pliantness of their soft and tender substance. Lastly we must here admonish the Chirurgion; that small Wounds and such as no Artisan will judge deadly, do divers times kill by reason of a certain occult and ill disposition of the wounded, and incompassing bodies; for which cause we read it observed by *Hippocrates*, that it is not sufficient for the Physitian to performe his duty, but also externall things must be rightly prepared, and fitted.

CHAP. V.

Of the Cure of Wounds in generall.

The Chirurgion ought for the right cure of wounds to propose unto himselfe the common and generall indication: that is, the uniting of the divided parts, which indication in such a case is thought upon and known even by the vulgar: for that which is disjoyned desires to be united, because union is contrary to division. But by what means such union may be procured, is only known to the skilfull Artisan. Therefore we attain unto this chief and principall Indication by the benefit of nature as it were the chief Agent, and the work of the Chirurgion as the servant of nature. And unless nature shall be strong, the Chirurgion shall never attain to his conceived, and wished for end: therefore that he may attain hereto, he must performe five things; the first is, that if there be any strange bodies, as peeces of Wood, Iron, Bones, bruised flesh, congealed blood, or the like, whether they have come from without, or from within the body, and shall be by accident fastened or stuck in the wound, he must take them away, for otherwise there is no union to be expected.

What wounds are dangerous.

What least dangerous.
What deadly.
Hip. aphor. 19. Lib. 6.

Why round Wounds are difficult to heal.

Hip. lib. de ulcer. Hip. aph. 66. lib. 6.

What a *Callus* is and whence it proceeds.

Small and contemptible Wounds often prove mortall.

Aphor. 1. se. 1.

The generall Indication of Wounds.

Five things necessary for uniting wounds.

Another is, that he join together the lips of the Wound; for they cannot otherwise be agglutinated and united. The third is, that he keep close together the joined lips. The fourth, that he preserve the temper of the wounded part, for the distemper remaining, it is impossible to restore it to its unity. The fifth is, that he correct the accidents, if any shall happen, because these urging, the Physitian is often forced to change the order of the cure.

All strange and externall bodies must be taken away, as speedily as is possible, because they hinder the action of nature intending unity, especially if they press or prick any Nervous body, or Tendon, whence pain or an Abscess may breed in any principall part, or other serving the principall.

Yet if by the quick and too hasty taking forth of such like bodies there be fear of cruell pain or great effusion of blood, it will be far better to commit the whole work to nature than to exasperate the Wound by too violent hastening.

For nature by little and little will exclude, as contrary to it, or else together with the Pus, what strange body soever shall be contained in the wounded part. But if there shall be danger in delay, it will be fit the Chirurgeon fall to work quickly, safely, and as mildly as the thing will suffer: for effusion of blood, swooning, convulsion and other horrid symptoms, follow upon the too rough and boystrous handling of Wounds, whereby the Patient shall be brought into greater danger than by the Wound it self.

Therefore he may pull out the strange bodies, either with his fingers, or with instruments, fit for that purpose: but they are sometimes more easily and sometimes more hardly pulled forth, according as the body infixed is either hard or easie to be found or pulled out. Which thing happens according to the variety of the figure of such like bodies, according to the condition of the part it self, soft, hard, or deep, in which these bodies are fastened more straitly or more loosely: and then for fear of inferring any worse harm, as the breaking of some Vessell: but how we may perform this first intention, and also the expression of the instruments necessary for this purpose, shall be shown in the particular treaties of Wounds made by Gun-shot, Arrows and the like.

But the Surgeon shal attain to the second and third scope of curing Wounds by two and the same means, that is, by ligatures & sutures: which notwithstanding before he use he must well observe whether there be any great flux of blood present, for he shall stop it if it be too violent; but provoke it, if too slow, (unless by chance it shall be powred out into any capacity or belly) that so the part freed from the superfluous quantity of blood may be less subject to inflammation. Therefore the lips of the Wound shall be put together, and shall be kept so joined by suture and ligatures: Not truly of all, but only of those which both by their nature, and magnitude, as also by the condition of the parts in which they are, are worthy and capable of both the remedies. For a simple and small solution of continuity, stands only in need of the Ligature which we call incarnative, especially, if it be in the Arms or Legs, but that which divides the Muscles tranversly, stands in need of both Suture and Ligature; that so the lips which are somewhat far distant from each other, and as it were drawn towards their beginning, and ends may be conjoyned.

If any portion of a fleshy substance by reason of some great cut shall hang down, it must necessarily be adjoyned and kept in the place by Suture. The more notable and large Wounds of all the parts, stand in need of Suture, which do not easily admit a Ligature, by reason of the figure and site of the part in which they are, as the Ears, Nose, Hairy-scalp, Eye-lids, lips, Belly and Throat.

There are three sorts of Ligatures, by the joint consent of all the Ancients. They commonly call the first, a Glutinative, or Incarnative; the second Expulsive, the third Retentive. The Glutinative or Incarnative is fit for simple, green and yet bloody Wounds. This consists of two ends, and must so be drawn, that beginning on the contrary part of the Wound, we may so go upwards, partly crossing it, and going downwards again, we may closely joyn together the lips of the Wound. But let the Ligature be neither too strait, lest it may cause inflammation or pain; nor too loose, lest it be of no use, and may not well contain it.

The Expulsive Ligature is fit for sanious and fistulous Ulcers, to press out the filth contained in them. This is performed with one Rowler, having one simple head; the beginning of binding must be taken from the botome of the Sinus, or bosome thereof; and there it must be bound more straihgty, and so by little and little going higher, you must remit some thing of that rigour, even to the mouth of the Ulcer, that so (as we have said) the sanious matter may be pressed forth.

The Retentive Ligature is fit for such parts as cannot suffer strait binding, such are the Throat, Belly, as also all parts oppressed with pain; For the part vexed with pain, abhorreth binding. The use thereof, is to hold to locall Medicines. It is performed with a Rowler, which consists some wiles of one, some whiles of more heads. All these Rowlers ought to be of linnen, and such as is neither too new, nor too old, neither too course, nor too fine. Their breadth must be proportionable to the parts to which they shal be applyed; the indication of their largeness, being taken from their magnitude, figure and site. As we shall shew more at large in our Tractates of Fractures and Dislocations.

Ligatures and Sutures for to conjoyn and hold together the lips of wounds.

Three sorts of Ligatures. What an incarnative Ligature is.

What an expulsive.

What the retentive.

What the rowlers must be made of.

The Chirurgeon shall perform the first scope of curing Wounds, which is of preserving the temper of the Wounded part, by appointing a good order of diet by the Prescript of a Physitian, by using universall and locall Medicines. A slender, cold and moist Diet must be observed, untill that time be passed, wherein the Patient may be safe and free from accidents which are usually feared. Therefore let him be fed sparingly, especially if he be plethorick; he shall abstain from salt and spiced flesh, and also from Wine; If he shall be of a cholericke or sanguine nature: In stead of Wine he shall use the decoction of Barly or Liquorice, or Water and Sugar. He shall keep himself quiet; for rest is (in *Celsus* opinion) the very best Medicine. He shall avoid Venery, Contentions, Brawls, Anger, and other perturbations of the mind. When he shall seem to be past danger, it will be time to fall by little and little to his accustomed manner and diet of life. Universall remedies are Phlebotomies and purging, which have force to divert and hinder the defluxion, whereby the temper of the part might be in danger of change.

For Phlebotomy it is not alwayes necessary, as in small Wounds and bodies, which are neither troubled with ill humors, or Plethorick: But it is only required in great Wounds, where there is fear of defluxion, pain, *Delirium*, Raving and unquietness; and lastly in a body that is Plethorick, and when the joynts, tendons, or nerves are wounded. Gentle purgations must be appointed, because the humors are moved and intraged by stronger; whence there is danger of defluxion and inflammation: wherefore nothing is to be attempted in this case, without the advice of a Physitian.

The Topick and particular Medicines are Agglutinative, which ought to be indued with a drying and astringive quality, whereby they may hold together the lips of the Wound, and drive away defluxion, having alwayes regard to the nature of the part and the greatness of the disease. The Simple Medicines are *Olibanum*, *Aloes*, *Sarcocolla*, *Bole-Armenick*, *Terra sigillata*, *Sanguis Draconis*, Common and Venice, Turpentine, Gum, *Elemmi*, Plantane, Horse-tail, the greater Comfery, *Parina Volatilis* and many other things of this kind, which we shall speak of hereafter in our Antidotary.

The fifth scope of healing Wounds, is the correction of those Symptomes or Accidents which are accustomed to follow Wounds, which thing verily makes the Chirurgeon have much to do; For he is often forced to omit the proper cure of the disease, so to resist the accidents and symptomes, as bleeding, pain, inflammation, a fever, convulsion, palsie, talking idly, or distraction, and the like. Of which we shall treat briefly and particularly, after we have first spoken of Sutures as much as we shall think fitting for this place.

CHAP. VI.

Of Sutures.

When Wounds are made alongst the thighes, legs, and arms, they may easily want Sutures, because the solution of continuity is easily restored by Ligatures, but when they are made overthwart, they require a Suture, because the flesh and all such like parts, being cut are drawn towards the sound parts; whereby it comes to pass that they part the further each from other; wherefore that they may be joynd and so kept, they must be sowed, and if the Wound be deep, you must take up much flesh with your needle; for if you only take hold of the upper part, the Wound is only superficially healed: but the matter shut up, and gathered together in the bottome of the Wound, will cause abscesses and hollow Ulcers: Wherefore now we must treat of making of Sutures.

The first, called *Interpunctus*, leaves the distance of a fingers breadth, and therefore is fit for the green Wounds of the fleshy parts, which cannot be cured with a Ligature, and in which no heterogeneous or strange body remains; It is performed after this manner. You must have a smooth needle with a thred in it, having a three square point, that so it may the better enter the skin, with the head of it somewhat hollowed, that the thred may lie therein; for so the needle will the better go through. You must also have a little pipe with a hole or window in the end, which you must hold and thrust against the lip of the Wound, that it be not moved to the one side or other, whilst you thrust through the needle: And that we may see through that Window when the needle is thrust through, and also draw it together with the thred, and withall hold the lip of the Wound in more firmly, that it follow not at the drawing forth of the needle and thred. Having thus pierced the lips of the Wound, tie a knot, neer to which cut off the thred; lest that if any of it be left below the knot, it may so stick to the Emplasters that it cannot be plucked and separated from them without pain, when they are taken off. But you must note the first stitch must be thrust through the midst of the Wound, and then the second must be in that space which is between the midst and one of the ends; but when you have made your stitches, the lips of the Wound must not be too closely joined, but a little space must be left open between them, that the matter may have free passage forth, and inflammation and pain may be avoided: otherwise if they shall be closely joined together without any distance between, a tumor after arising when the matter shall come to suppuration, the lips will

Why and how the temper of the wounded part must be preserved.

In what wounds bloodletting is not necessary.

What medicines are to be judged agglutinative.

What wounds stand in no need of a suture.

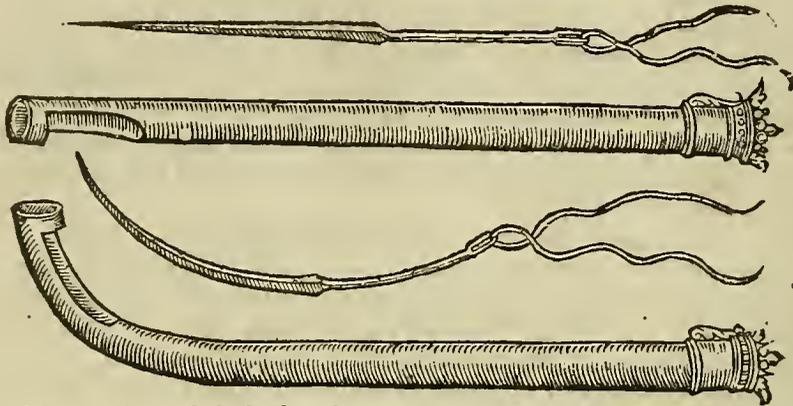

The first manner of suture.

The form of your needle.

The form of the pipe with a window in it.

be so much distended that they may easily be broken by the stiffness of the thred. But you must neither take hold of too much nor too little flesh with your needle, for too little will not hold, and too much causeth pain and inflammation. And besides leaves an ill favoured scar. Yet in deep wounds, such as are those which are made in the thicker muscles, the needle must be thrust home, that so it may comprehend more of the fleshy substance; lest the thred drawn away by the weight of the flesh not taken hold of, may be broken. But oft-times wounds are seen made in such places as it would be needfull, the Chirurgion should have a crooked needle and pipe, otherwise the Suture will not succeed according to his desire. Wherefore I have thought good to set forth both their figures, that you may use either as occasion shall serve.

The Figure of Pipes with fenestels in them, and Needles fit for Sutures.

The 2. means of Suture.

The second Suture is made just after the same manner as the Skinner sows their fells or furs. And the guts must be sowed with this kind of Suture, (if they shall be at any time wounded) that the excrements come not forth by the wound.

The third manner of Suture.

The third Suture is made by one or more needles having thred in them, thrust through the wound, the thred being wrapped to and again at the head and the point of the needle, as boyes use to fasten their needle, for fear of losing it, in their caps, or clothes. This kind of Suture is fit in the curing and healing of Hare-lips, as we shall shew you hereafter expressed by a Figure.

The 4. kind of Suture termed *Gastroraphia*.

The fourth kind of Suture is termed *Gastroraphia*, invented for the restoring and uniting the great Muscles of the *Epigastrium*, or lower belly, cut with a great wound together with the *Peritoneum* lying under them. The manner whereof we shall shew in due place.

The 5. kind called the Dry Suture.

The fifth kind is called the dry Suture, which we use only in the wounds of the face, which also we will describe in its proper place.

CHAP. VII.

Of the flux of blood, which usually happens in Wounds.

The signs of blood flowing from an artery.

Oft-times great bleeding follows upon wounds, by reason of some vessel cut, broken, or torn, which there is need to heal and help diligently, because the blood is the treasure of nature, without which life cannot consist. The blood which floweth from an Artery, is thus known. It is more subtile, it runs forth as it were leaping, by reason of the vitall spirit contained together with it in the Arteries. On the contrary that which floweth from a Vein is more gross, black, and slow. Now there are many wayes of stanching blood.

The first way of staying bleeding.

The first and most usuall is that, by which the lips of the Wound are closed, and unless it be somewhat deep, are contained by Medicines which have an astringent, cooling, drying, and glutinous faculty; As *terre sigill. Boli Armeni*, ana $\zeta\beta$, *Thuris*, *Mastichis*, *Myrrha*, *Aloes*, ana ζij , *Farinae volat. molend.* ζij , *Fiat pulvis qui albumine ovi excipitur.* Or *Rx. Thuris & Aloes, ana partes equales.* Let them be mixt with the white of an Egge, and the down of a hare, and let the pledgets be dipped in these Medicines, as well those which are put unto the Wound as those which are applyed about it. Then let the Wound be bound up with a double clop and fit Ligature, and the part be so seated as may seem the least troublesome and most free from pain.

The 2. manner of stanching it.

But if the blood cannot be stayed by this means, when you have taken off all that covereth it, you shall press the Wound and the orifice of the Vessell with your thumb, so long untill the blood shall be concrete about it, into so thick a clot as may stop the passage.

The 3. way by binding of the vessels.

But if it cannot be thus stayed, then the Suture (if any be) must be opened, and the mouth of the Vessell towards the originall or root, must be taken hold of, and bound with your needle and thred, with as great a portion of the flesh as the condition of the part will permit. For thus I have staid great bleedings, even in the amputation of members, as I shall shew in fit place. To perform this work, we are often forced to divide the skin which

which covereth the wounded vessell. For if the Jugular vein, or Artery be cut, it will contract and with draw it self upwards and downwards. Then the skin it self must be laid open under which it lyeth, and thrusting a needle and thred under it, it must be bound as I have often done. But before you loose the knot, it is fit the flesh should be grown up, that it may stop the mouth of the vessell, lest it should then bleed.

An admonition

But if the condition of the part shall be such as may forbid this comprehension; and binding of the vessell, we must come to *Escharoticks*, such as are the powder of burnt *Vitriol*, the powder of Mercury, with a small quantity of burnt Allum; and *Causticks* which cause an *Eschar*. The falling away of which must be left to nature, and not procured by art, lest it should fall away before that the orifice of the vessell shall be stoped with the flesh, or clotted blood.

The 4 way by Escharoticks.

But sometimes it happens that the Chirurgeon is forced wholly to cut off the vessell it self, that thus the ends of the cut vessell withdrawing themselves, and shrincking upwards and downwards, being hidden by the quantity of the adjacent and incompassing parts, the flux of the blood, which was before not to be staid, may be stoped with lesse labour. Yet this is an extream remedy and not to be used, unlessse you have in vain attempted the former.

The 5 way by cutting off the vessels.

CHAP. VIII.

Of the pain which happens upon wounds.

He pains which follow upon wounds ought to be quickly asswaged, because nothing so quickly dejects the powers, and it alwayes causes a defluxion, of how good soever a habit and temper the body be of; for Nature ready to yeeld assistance to the wounded part, alwayes sends more humors to it, than are needfull for the nourishment thereof, whereby it comes to passe that the defluxion is easily increased, either by the quantity, or quality, or by both.

Pain weakeneth the body, and causes defluxions.

Therefore to take away this pain, the author of defluxion, let such medicines be applyed to the part as have a repelling and mitigating faculty; as R. *Olei Myrtili*, & *Rosarum*, ana ζ ij, *Cera alb.* ζ i, *Farina hordei*, ζ ss, *Boli armeni*, & *terra sigillat.* ana ζ vj, Melt the Wax in the oyls, then incorporate all the rest, and according to Art, make a medicine to be applyed about the part: or R. *Emplast. Diacalith.* ζ iv, *Ole. Rosar.* & *aceti*, ana ζ ss, *liquifiant simul*, and let a medicine be made for the fore mentioned use. Irrigations of oyl of Roses and Myrtiles, with the white of an Egge, or a whole Egge added thereto, may serve for lenitives, if there be no great inflammation; Rowlers and double cloaths moystened in Oxycrate, will be also convenient for the same purpose. But the force of such medicines must be often renewed, for when they are dryed, they augment the pain. But if the pain yeeld not to these, we must come to narcotick Medicines, such as are the Oyl of Poppy, of Mandrake, a cataplasim of Henbane and Sorrell, adding thereto Mallows and Marsh-mallows, of which we spoke formerly in treating of a Phlegmon.

Divers antidynes or medicines to asswage pain.

Lastly, we must give heed to the cause of the pain, to the kind and nature of the humor that flows down, and to the way which nature affects: for according to the variety of these things, the Medicines must be varied, as if heat cause pain, it will be asswaged by application of cooling things; and the like reason observed in the contrary; if Nature intend suppuration, you must help forwards its indeavours with suppurating medicines.

CHAP. IX.

Of Convulsion by reason of a Wound.

Convulsion is an unvoluntary contraction of the Muscles (as of parts movable at our pleasure) towards their originall, that is, the Brain and Spinal Marrow, for by this the convulsed member or the whole body (if the convulsion be universall) cannot be moved at our pleasure. Yet motion is not lost in a Convulsion as it is in a Palsie, but it is only depraved: and because sometimes the Convulsion possesseth the whole body, otherwhiles some part thereof, you must note that there are three kinds of Convulsions in generall.

What a Convulsion is.

The first is called by the Greeks *Tetanos*, when as the whole body grows stiffe like a stake that it cannot be moved any way.

Three kinds of an universall Convulsion.

The second is called *Opi sphotonos*, which is when the whole body is drawn backwards.

The third is termed *Emprosphotonos* which is when the whole body is bended or crooked forwards. A particular Convulsion is, when as the Muscle of the Eye, Tongue, and the like parts which is furnished with a Nerve, is taken with a Convulsion. Repletion or Inanition, Sympathy or consent of pain cause a Convulsion. Abundance of humors cause Repletion, dulling the body by immoderate eating and drinking, and omission of exercise, or any accustomed evacuation, as suppression of the Hemorrhoides, and courses: for hence are such like excrementitious humors drawn into the Nerves, with which they being replete and filled, are dilated more than is fit, whence necessarily becoming

Three causes of a Convulsion. Causes of Repletion.

more short, they suffer Convulsion. Examples whereof appear in Leather and Lute or Viol-strings, which swoln with moisture in a wet season are broken by repletion.

Causes of Inanition.

Immoderate vomitings, fluxes, bleedings, cause Inanition or Emptiness, wherefore a Convulsion caused by a wound, is deadly: as also by burning feavers. For by these and the like causes, the inbred & primogeneous humidity of the Nerves is wasted, so that they are contracted like leather which is shrunk up, by being held too neer the fire, or as fiddle strings which dried with Summers heat, are broken with violence, such a convulsion is incurable: For it is better a Feaver follow a Convulsion, than a Convulsion a Feaver; as we are taught by Hippocrates, so that such a Feaver be proportionall to the strength of the convulsifick cause, and the Convulsion proceed from Repletion; for the abundant and gross humor causing the Convulsion is digested and wasted by the feaverish heat.

Causes of convulsion by consent of pain.

The causes of a convulsion by reason of pain, are either the puncture of a Nerve, whether it be by a thing animal, as by the biting of a venemous beast; or by a thing inanimate, as by the prick of a needle, thorn or pen-knife; or great & piercing cold, which is hurtfull to the wounds, principally of the nervous parts; whereby it comes to pass, that by causing great and bitter pain in the nerves they are contracted towards their original, that is, the Brain, as if they would crave succour from their parents in their distressed estate. Besides also, an ill vapour carried to the brain from some putrefaction so vellicateth it, that contracting it self, it also contracteth together with it all the Nerves and Muscles, as we see it happeneth in those which have the falling sickness. By which it appears that not only the brain it self suffereth together with the Nerves, but also the Nerves with the Brain. The signs of a Convulsion are difficult, painfull and depraved motions, either of some part or of the whole body, turning aside of the Eyes and whole Face, a contraction of the Lips, a drawing in of the Cheeks, as if one laughed, and an univerfall sweat.

Signs of a convulsion.

CHAP. X.

The cure of a Convulsion.

The cause of a Convulsion by Repletion.
The cure of

He cure of a Convulsion, is to be varied according to the variety of the convulsive cause, for that which proceeds from Repletion must be otherwise cured, than that which is caused by an Inanition; and that which proceeds of pain, otherwise than either of them. For that which is caused by repletion is cured by discussing and evacuating medicines: as by diet conveniently appointed, by purging, bleeding, digestive locall Medicines, exercise, frictions, sulphurous baths and other things (appointed by the prescription of some learned Physitian which shall oversee the cure, which may consume the superfluous and excrementitious humors that possess the substance of the Nerves, and habit of the body. The locall remedies are Oyls, Unguents and Liniments, with which the Neck, back-bone and all the contracted parts shall be anointed. The Oyls are, the oyl of Foxes, Bayes, Cammomill, Worms, Turpentine, of *Costus*, of *Castoreum*: The Oyntments are *Vnguentum Arragon*, *Agrippæ*, *de Althæa*, *Martiatum*. This may be the form of a Liniment; *R. Olei chamem. & Laurin. ana ℥ ij*, *Olei Vulp. ℥ i*, *Vnguenti de Althæa & Marti. an. ℥ β*, *Axungie vulpæ, ℥ i*, *Aque vitæ, ℥ i β*, *Cere quantum sufficit*. Make a Liniment for your use, or *R. Olei Lumbric. de Spica & de Castoreo, an. ℥ iij*, *Axung. hum. ℥ i*, *Sulphuris vivi, ℥. β*. *Cere quantum sufficit*. Make a Liniment, or *R. Vnguenti Martiati, & Agrip. an. ℥ iij*. *Olei de Terebinth. ℥ i β*, *Olei Salvia, ℥ β*, *Aque vitæ ℥ i*, *Cere ℥ i β*, *fiat linimentum*. But this disease is cured by slender diet, and sweating with the Decoctions of *Guaiacum*, because by these remedies the gross, tough, and viscid excrements, which are in fault, are digested.

The cure of a Convulsion caused by inanition.

A Convulsion proceeding of Inanition is to be cured by the use of those things, which do wholesomly and moderately nourish. And therefore you must prescribe a diet consisting of meats full of a good nourishment, as broaths and cullices of Capons, Pigeons, Veal, & Mutton, boyling therein Violet and Mallow leaves. Conserves must be ordained, which may strengthen the debilitated powers, and humect the habit of the body, such as are the Conserves of Bugloss, Violets, Borage and water Lillies. The following broath will be profitable, *R. Lactuce, Buglos. & portul. an. M i*, *quatuor seminum frigid. major. an. ℥ β*, *seminis Barberis ℥ i*. Let them all be boyled with a chicken, and let him take the broath every morning. If thirst oppresse him, the following Julep will be good. *R. Aque rosar. ℥ iv*, *Aque viol. ℥ β*, *Saccari albisimi ℥ vi*, *fiat Julep, utatur in siti*. If the Patient be bound in his body, emollient and humecting Clysters shall be appointed, made of the decoction of a sheeps head and feet, Mallows, Marsh Mallows, Pellitory of the wall, Violet leaves, and other things of the like faculty; or that the remedy may be more ready and quickly made: let the Clysters be of Oyl and Milk. Topick remedies shall be Liniments and Baths. Let this be the example of a Liniment. *R. Olei Viol. & Amygdal. dulc. an. ℥ ij*, *Olei Lilior. & Lumbric. an. ℥ i*, *Axungie porci recentis, ℥ iij*, *Cere novæ quantum sufficit, fiat Linimentum*, with which let the whole spine and part affected be anointed: This shall be the form of an emollient and humecting bath. *R. Fol. Malvæ, Bis Malvæ, Pariet. ana M vi*, *Seminis Lini & fenug. ana ℥ β*, *Caquantur in aqua communi, addendo Olei Lilior. ℥ viij*. Make a Bath: into which let the Patient enter when it is warm. When he shall come forth of the Bath, let him be dried with

An Emollient Liniment for any Convulsion

An Emollient and humecting Bath.

with warm clothes, or rest in his bed avoiding sweat. But if the patient be able to undergo the charge, it will be good to ordain a bath of milk, or oyl alone, or of them equally mixt together.

CHAP. XI.

Of the cure of a Convulsion, by sympathy and pain.

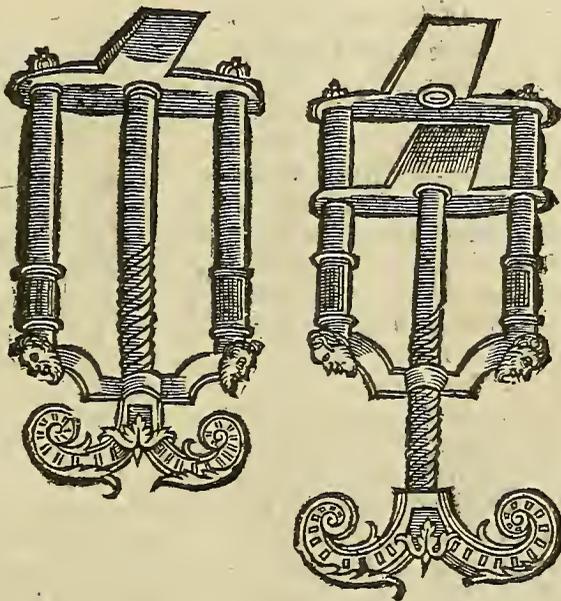

Convulsion which is caused both by consent of pain and Communication of the affect, is cured by remedies which are contrary to the dolorifick cause. For thus if it proceed from a puncture or venemous bite, the wound must be dilated and enlarged by cutting the skin, that so the venenate matter may flow forth more freely, for which purpose also medicines which are of a thin and liquid consistence, but of a drying and digestive faculty shall be powred in, to call forth and dissolve the virulency, as Treacle and Mithridate, dissolved in *Aqua vita*, with a little of some mercuriall powder: for this is a noble antidote. Also cupping glasses and scarifications will be good. Lastly, the condition of all dolorifick causes, shall be oppugned by ths opposition of contrary remedies, as if pain by reason of a pricked nerve or tendon, shall cause a Convulsion, it must presently be resisted by proper remedies, as oyl of Turpentine, of *Euphorbium*, mixt with *Aqua vita*, and also with other remedies appropriated to punctures of the nerves. If the pain proceed from excess of cold, because cold is hurtfull to the brain, the spinall marrow, and nerves; the patient shall be placed in a hot air, such as that of a hot-house, or stove, all the spine of his back and convulsed parts, must be anointed with the hot liniments above mentioned: for that is much better, than suddenly to expose him from the conceived convulsifick cause to a most hot fire or warm Bath. In the mean time the Chirurgion must take diligent heed, that as soon as the signs of the Convulsion to come, or already present, or at hand, do shew themselves, that he put a stick between the patients teeth, lest they be fast locked by the pertinacious contraction of the Jaws: for many in such a case have bit off their tongues, for which purpose he shall be provided of an instrument called *Speculum Oris*, which may be dilated and contracted according to your mind by the means of a screw, as the figures underneath demonstrate, the one presenting it open and somewhat twined up, and the other as it is shut.

The Cure of a Convulsion by a puncture, or bite.

A worthy *Alexipharmacum* or Antidote.

You must hinder the locking of the teeth.

The Figure of a *Speculum Oris*, to open the teeth when they are locked or held fast together.

CHAP. XII.

Of the Palsie.

The Palsie is the resolving or mollification of the nerves, with privation of sense and motion, not truly of the whole body, but of the one part thereof, as of the right or left side. And such is properly named the Palsie: for otherwise and less properly the resolution of some one member is also called the Palsie: for when the whole body is resolved, it is an Apoplexy. Therefore the Palsie sometimes takes half the body, otherwhiles the upper parts which are between the navell and the head, otherwhiles

What a Palsie is. The difference, ces thereof.

therwhiles the lower which are from the navell to the feet; sometimes the tongue, gullet, bladder, yard, eyes; and lastly, any of the particles of the body.

How it differs
from a Con-
vulsion.

It differs from a Convulsion in its whole nature. For in a convulsion, there is a contention and contraction of the part, but in this a resolving and relaxation thereof: besides, it commonly happeneth that the sense is either abolished or very dull, which usually remains perfect in a Convulsion. There are some which have a pricking, and as it were great pain in the part.

The causes.

The causes are internall or externall, the internall are humors obstructing one of the ventricles of the brain, or one side of the spinall marrow, so that the animall faculty, the worker of sense and motion, can not by the nerves come to the part to perform its action. The externall causes are a fall, blow, and the like injuries, by which oft-times the joints are dislocated, the spinall marrow wrested aside, and constrictions and compressions of the *Vertebrae* arise, which are causes that the animall spirit cannot come to the Organs in its whole substance. But it is easy by skill in Anatomy perfectly to understand by the resolved part the seat of the morbidick cause, for when there is a Palsie properly so called, that is, when the right or left side is wholly seized upon, then you may know that the obstruction is in the brain, or spinall marrow; but if the parts of the head being untoucht, either of the sides being wholly resolved, the fault remains in the originall of the spinall marrow; if the armes be taken with this disease, we may certainly think that the matter of the disease lies hid in the fifth, sixth, and seventh *Vertebra* of the neck. But if the lower members languish, we must judge the Paralytick cause to be contained in the *Vertebrae* of the loins and holy bone. Which thing the Chirurgion must diligently observe that he may alwaies have recourse to the originall of the disease. The Palsie which proceeds from a nerve cut, or exceedingly bruised, is incurable, because the way to the part by that means is shut against the animall spirit. Old men scarce or never recover of the Palsie, because their native heat is languid, and they are oppressed with abundance of excrementitious humors; neither doth an inveterate Palsie which hath long possessed the part, neither that which succeeds an Apoplexy, yeeld us any better hope of cure. It is good for a fever to come upon a Palsie, for it makes the dissipation of the resolving and relaxing humor, to be hoped for. When the member affected with the palsie, is much wasted, and the opposite on the contrary, much encreased in quantity, heat and colour, it is ill: for this is a signe of the extreame weakness of the afflicted part, which suffers it self to be defrauded of its nourishment, all the provision flowing to the sound or opposite side.

It is good for a
feaver to hap-
pen upon a
palsie.

CHAP. XIII.

Of the cure of the Palsie.

IN the cure of the Palsie we must not attempt any thing, unless we have first used generall remedies, diet and purging; all which care lyeth upon the learned and prudent Physitian. The Decoction of *Guaiacum* is very fit for this purpose, for it procures sweat and attenuates, digests and drieth up all the humidity which relaxeth the nerves: but when sweat doth not flow it shall not be

The decoction
of *Guaiacum* is

members.

unprofitable to put about the resolved members, bricks heated red hot in the fire and quenched in a decoction of Wine, Vinegar, and resolving herbs, or also stone bottles, or Ox and Swine bladders, half filled with the same decoction; for such heat which is actually resuscitateth and strengthneth the heat of the part, which in this disease is commonly very languid: Then the patient shall go into a bathing-tub, which is vaulted or covered over just as we have described in our Treatise of Baths; that so he may receive the vapour of the following decoction. *R. fol. Salviae, Lavend. Lauri major. Absinth. Thym. Angelicae, Rutae, ana M.ß. Florum Chamem. Melil. Anethi, Anthos. ana P ij. Baccar. Laur. & Juniper. Conguassatar. ana ʒ j. Caryophyl. ʒ ij. Aquae fontanae & Vini albi, ana lbiv.* Let them be all put in the vessel mentioned in the Treatise lately described for use. The patient shall keep himselfe in that Bathing-tub, as long as his strength will give him leave, then let him be put into his bed well covered, where he shall sweat again, be dried and rest. Then let him be presently anointed with the following ointment, which *Leonellus Faventius* much commends, *R. Olei Laurini & de Terebinth. ana ʒ iij. Olei Nardini & petrolei, ana ʒ j. Vini malvatici, ʒ iv. Aqua vitae ʒ ij. Pyrethri, Piperis, Sinap. Granor. Junip. Gummi hederae, anacard. Ladani puri, an. ʒ iß. Terantur & misceantur omnia cum Oleis & Vino: bulliant in vase duplici usque ad Vini consumptionem, facta forti expressione, adde Galbani, Bdellii, Euphorbii, Myrrhae, Castorei, adipis ursi, Anatis, Ciconiae, an. ʒ ij.* Make an ointment in form of a liniment, adding a little wax if need shall require. Or you shall use the following remedy approved by many Physitians. *R. Myrrhae & Aloes, Spicae nardi, Sanguinis draconis, thuris, cpeponacis, Bdellii, Carpobalsami, anomi, sarcocollae, croci, mastice. gummi arabici, styrac. liquidae, ladani, castorei, ana ʒ ij. Moschi, ʒ j. Aqua vitae, ʒ j. Terebinthinae venetae, ad pondus omnium, pulverabuntur pulverisanda & gummi eliquabuntur cum aqua vitae & aceti tantillo.* And let them all be put in fit vessels, that may be distilled in *Balneo Mariae*, and let the spine of the back, and paralytick limbs be anointed with the liquor which comes from thence. I have often tried the force of this following Medicine. *R. rad. Angel. Ireos. floren. gentian. cyperi, ana ʒ j. Calami aromati. Ci-*

nam. Caryophil. nucis Mosch. macis, ana ℥ij. Salvie major. Inæ arthriticæ, Lavend. rorism. sat. reia, pulleg. calament. mentastri, ana M β. florum chamem. melil. hyperic. anthos, stæchad. ana P j. Conciſa omnia contundantur. & in Aqua vit. & Vini malvat. an. ℥ij. infundantur. And let them be distilled in Balneo Mariæ, like the former let the affected parts be moistned with the distilled liquor, of which also you may give the patient a spoon full to drink in the morning with some Sugar. For thus the stomach will be heated, and much phlegm contained therein as the fuel of this disease, will be consumed.

You must also appoint exercises of the affected parts, and frequent and hard frictions, with hot linnen clothes, that the native heat may be recalled and the excrements contained in the parts digested: you may also use the Chymicall oyls of Rosemary, Tyme, Lavander, Cloves, Nutmegs; and lastly, of all spices, the manner of extracting whereof we shall hereafter declare in a peculiar Treatise.

CHAP. XIV.

Of Sowning.

Sowning is a sodain and pertinacious defect of all the powers, but especially the virall; in this the patients lie without motion and sense, so that the Ancients thought that it differed from death only in continuance of time. The cause of sowning, which happens to those that are wounded is bleeding, which causeth a dissipation of the spirits: or fear, which causeth a sodain and joint retirement of the spirits to the heart. Whence follows an intermission of the proper duty, as also of the rest of the faculties, whilst they being thus troubled, are at a stand. Also Sowning happens by a putrid and venenate vapour, carried to the heart by the arteries, and to the brain by the nerves; by which you may gather, that all sowning happens by three causes. The first is, by dissipation of the spirits and native heat, as in great bleeding. And then by the oppression of these spirits by obstruction, or compression, as in fear, or tumult; for thus the spirits fly back hastily from the surface and habit of the body, unto the heart and center. Lastly, by corruption, as in bodies filled with humours, and in poysonous wounds. The signs of sowning are paleness, a dewy and sodain sweat arising, the failing of the pulse, a sodain falling of the body upon the ground without sense and motion, a coldness possessing the whole body, so that the patient may seem rather dead, than alive. For many of these who fall into a sown die unless they have present help.

Therefore you shall help them, if when they are ready to fall, you sprinkle much cold water in their face, if that the sowning happen by dissipation of the spirits, or if they shall be set with their faces upwards, upon a bed or on the ground, as gently as may be; and if you give them bread dipped in wine to hold and chew in their mouths. But if it be caused by a putrid vapour and poysonous air, you shall give them a little Michridate or Treacle in Aqua vitæ with a spoon, as I usually do to those which have the plague, or any part affected with a Gangrene, or spacell. But if the patients cannot be raised out of their sownes, by reason of the pertinacious oppression and compression of the spirits about the heart, you must give them all such things as have power to diffuse, call forth and resuscitate the spirits, such as are, strong wines to drink, sweet perfumes to smell: You must call them by their own name loud in their eare, and you must pluck them somewhat hard by the hairs of the Temples, and neck. Also rub the temples, nostrils, wrists and palms of the hands with Aqua vitæ, wherein Cloves, Nutmegs, and Ginger have been steeped.

What sowning
is.

Three causes
of sowning:

sowning caused
by dissipation
of spirits.

The cure of
sowning caused
by a venenate
air.

The cure of
sowning caused
by oppression
& obstruction.

CHAP. XV.

Of Delirium (i.) *Raving, Talking idly or Doting.*

Doting or talking idly, here is used for a symptome which commonly happeneth in feavers caused by a wound, and inflammation; and it is a perturbation of the phantasie, and function of the mind, not long induring. Wherefore such a doting happens upon wounds, by reason of vehement pain, and a feaver, when as the nervous parts as the joints, stomach, and midriffe, shall be violated.

For the Ancients did therefore call the Midriffe *Phrena*, because when this is hurt, as if the mind it self were hurt, a certain phrensie ensues; that is, a perturbation of the animall faculty, which is employed in ratiocination; by reason of the community which the *Diaphragma* hath with the brain, by the nerves, sent from the sixth conjugation, which are carried to the stomach. Therefore doting happens by too much much bleeding, which causeth a dissipation of the spirits, whereby it happens that the motions and thoughts of the mind erre, as we see it happens to those who have bled much in the amputation of a member. And it happens by the puncture of a venenous beast, or from seed retained or corrupted in the womb, or from a Gangrene or Sphacel, from a venenate and putrid air carried up to the brain, or from a sodain tumult & fear. Lastly, what things soever with any distemper especially hot, do hurt and debilitate the mind. These may cause doting by the afflux

midriffe.

The Cure
of

of humors, specially cholerick, by dissipation, oppression or corruption of the spirits. Therefore if it shall proceed from the inflammation of the brain, and *Meninges* or membranes thereof; after purging and blood-letting by the prescription of a Physitian, the hair being shaved or cut off, the head shall be fomented with rose vinegar, and then an Emplaister of *Diacalcitheos* dissolved in oyl and vinegar of Roses, shall be laid thereupon. Sleep shall be procured with Barly creams, wherein the seeds of white Poppy have been boiled, with broths made of the decoction of the cold seeds of Lettuce, Purslain, Sorrell, and such like. Cold things shall be applied to his nostrills, as the seeds of Poppy gently beaten with Rose water and a little vinegar. Let him have merry and pleasant companions that may divert his mind from all cogitation of sorrowful things, and may ease and free him of cares, and with their sweet intreaties may bring him to himself again. But if it happen by default of the spirits, you must seek remedy from these things which have been set down in the Chapter of Sowning.

The End of the Ninth Book.

OF THE GREENE AND BLOODY VVOVND OF EACH PART.

THE TENTH BOOK.

CHAP. I.

Of the kinds or differences of a broken skull.

Now that we have briefly treated of wounds in generall, that is, of their differences, signs, causes, prognosticks and cure, and also shewed the reason of the accidents and symptoms which usually follow and accompany them, it remains that we treat of them as they are incident to each part, because the cure of wounds must be diversly performed according to the diversity of the parts. Now we will begin with the wounds of the head. Therefore the head hath the hairy scalp lightly bruised without any wound, otherwhiles it is wounded without a Contusion, and sometimes it is both contused and wounded: but a fracture made in the skull, is sometimes superficially, sometimes it descends even to the *Diploe*, sometimes it penetrates through the 2 Tables, and the *Meninges* into the very substance of the brain; besides, the brain is oft-times moved and shaken with breaking of the internall veins, and divers symptoms happen when there appears no wound at all in the head: of all and every of which we will speak in order, and add their cure, especially according to the opinion of the divine *Hippocrates*. He in his Book of the wounds of the head, seems to have made 4 or 5 kinds of fractures of the skull. The first is called a fissure or fracture, the 2 a contusion or collision, the 3 is termed *Effractura*, the 4 is named *Sedes*, or a seat; the 5 (if you please to add it) you may call a Counterfissure, or as the interpreter of *Paulus* calls it, a *Resonitus*. As when the bone is cleft on the contrary side, to that which received the stroak. There are many differences of these 5 kinds of a broken skull. For some fractures are great, some small, and others indifferent; some run out to a greater length or bredth; others are more contracted; some reside only in the superficies; others descend to the *Diploe*, or else pierce through both the Tables of the skull; some run in a right line, others in an oblique and circular; some are complicated amongst themselves, as a fissure is necessarily and alwaies accompanied with a Collision or Contusion; and others are associated with divers accidents, as pain, heat, swelling, bleeding and the like. Sometimes the skull is so broken, that the membrane lying under it, is pressed with shivers of the bone, as with pricking needles. Somewhiles none of the bones falls off. All which differences are diligently to be observed, because they force us to vary the cure, and therefore for the help of memory, I have thought good to describe them in the following Table.

The differences of a broken head.

The kinds of a broken Skull out of *Hippocrates*.

Differences from their quantity. Differences from their figure. From their complication.

A Table of the fractures of the Skull.

Either manifest, and apparent, that is } To your sight,
} To your feeling,
} Or instrument.

On the side, as for example, when the right side of the bone of the forehead is stricken, the left is cleft.

In the same bone, and that two manner of wayes, as

Or from above to below, as when not the first Table which received the blow is cleft, but that which is under it.

Keep their naturall figure and site touching each other, whence proceeds that fracture of the skull which is called a fissure, which is

Or obscure and not manifest, when as not the part which received the blow is wounded, but the contrary thereto, and that happens either

In divers bones, to wit in such men as want sutures, or have them very close, or disposed otherwaies then is fit, and this opposition is either

From the right side to the left, and so on the contrary, as when the right Bregma is struck, and the left cleft.

From before to behind, and the contrary, as when the forehead is smitten, the nowle is cleft.

Or between both, that is, the obscure and manifest, as that which is termed a Capillary fissure, and is manifested by smearing it over with oyl, and writing ink.

Wholly, so that the particles of the broken bone removed from their seat, and falling down, press the membrane, whence proceeds that kind of effracture which retains a kind of attrition, when as the bone struck upon is broken as it were into many fragments, shivers and scales, either apparent, or hid in the sound bone, so that it is pressed down.

Or in some sort, as when the broken bone is in some part separated, but in others adheres to the whole bone, whence another kind of effracture arises; you may call it Arched, when as the bone so swells up, that it leaves an empty space below.

Or lose their site, and that either

Contusion, that is, a collision of a thing bruising, hard, heavy and obtuse, which shall fall or bee smitten against the head, or against which the head shall be knocked, so that the broken bones are divided, or

A fracture, or solution of continuity in the skull is caused either by

Or by incision of a sharp, or cutting thing, but that incision is made, either by

Succission, when the bone is so cut, that in some part it yet adheres to the sound bone.
Rescission, when the fragment falls down wholly broken off.
Or Seat, when the mark of the weapon remains imprinted in the wound that the wound is of no more length nor breadth than the weapon fell upon.

Another

Another Table of the differences of a fractured Skull.

		Simple, as when they are found solitary and by themselves.
The differences of fractures common to these of all other parts are drawn, either from	Their nature, according to which fractures are call'd,	Compound and that either
		Mutually with themselves, as a contusion, or collision with incision, a fissure with an effracture. Or with other symptomes, as swelling, pain, heat, bleeding, convulsion and the like.
	Their Quantity, whence they are called, great, indifferent and small, according to the tripla dimension of length, breadth and profunditie.	
	Their figure, from whence they are called	Right, Oblique, Transverse, Round, Triangular.
	Their site, whence they are termed on the fore or back, or the right or left, or the upper or lower part, or superficially and profound.	
	The part, whence it is called a Fracture of the Forehead, Nomi; Bregma, and Stony bones; and hence it is judged, what may be deadly or hopefull of recovery, easie or difficult to cure.	

CHAP. I I.

Of the causes and signs of a broken Skull.

The causes of a broken Skull are externall, as a fall, a blow or stroak with any kind of weapon, sharp, obtuse, heavy, hard, the bitings of Beasts and many other things of the like kind. But the signs by which we come to know that the Skull is broken, are of two kinds; for some of them are found out by the reasoning and discourse of the mind, other by the sense, as those which lay open the wound to the ey & hand.

The Rationall signs shew by these things which have happened upon the thing it self, whether it be, and of what sort it is. For you may know the skull is broken, if the Patient shall fall down with the stroak, or if he shall fall headlong from a high place upon some hard thing. If for sometime after the stroak, he shall lie without speaking, sight and hearing, if he shall have felt and feel much pain, so that he is often forced to put his hand to the Wound. But also the weapon is to be considered, that is, whether if it be heavy, obtuse, pricking or sharp. Also we must consider with what and how great strength the stroak was given, and with how great anger and from what distance the weapon fell. Also he must consider whether the Patient received the blow; with his head unarmed and naked; whether he fell into a fown presently after the blow; whether when he came to him self, he was in his right senses; whether his eyes were blinded, whether he were troubled with a giddiness or dizines, and whether he bled at the nose, mouth, ears, or eyes, and lastly whether he vomited. For Hippocrates wriees, that those who have their brain cut, must necessarily have a fever and vomiting of choler to ensue thereupon, which Galen confirming in his Commentary saith, that the same happens also when the Wound comes to the Membranes of the brain.

Also a dull sound as from a broken vessell coming from the skull, (the hairy scalp and Pericranium being taken off) and it being lightly smitten upon with an Iron probe, is said to be a sign of a fracture thereof, as it is recorded by Paulus Aegineta. Truly all these signs make a great conjecture or rather assuredness that the skull is wounded, and the brain hurt, as which cannot happen unless the bone be broken, as Celsus hath written. Yet many have had their skulls broken, who had no such sign immediately after the blow; but this is very seldome. But I do not think fit amongst so many signs, here to omit that which is set down by Guido. If any (saith he) will know in what place the skull is broke, let the Patient hold fast between his fore teeth, one end of a lute string or thread, and the Chirurgion hold the other in his hand; then let him lightly touch or play upon the string with his fingers; for in the very instant of the sound or stroke, the Patient will be certainly admonished, or perfectly perceive the part of the skull that is broken, and as overcome and forc'd by

The externall causes.

Rationall causes.

Aphor. 50. sec. 6.

Lib. 8. cap. 4.

by this sense of pain, will by lifting up his hand make demonstration thereof. As yet I have not been able to find the truth hereof by experience, although I have made tryall of it in many. Wherefore I cannot say any thing certainly of this sign, as neither of that which is mentioned by *Hippocrates* in *Coais Pres.* In such as you doubt, whether the bones of the skull be broken, or not, you must judg by giving them the stalk of the *Asphodill*, to chew on both sides of their jaws, but so that you bid them withall observe, whether they perceive any bone to crackle, or make a noise in their heads, for these which are broken seem to make a noise.

But passing over these things, now let us come to these signs, which may be obvious to our senses.

Hippocrates
and *Guidoes*
conjecturall
signs of a bro-
ken skull.

CHAP. III.

Of the signs of a broken skull, which are manifest to our sense.

THese signs are here said to be manifest to sense, which when the bone is bared, manifest the wound to our eyes, fingers and probe. But if the hairs stand upon one end in the wound, you may know the bone is broke, because the hair which yeelds to the violence of the blow, cannot be so cut, the bone which resists the stroak being not violated, as it is observed by *Hippocrates*; wherefore we may by the sight of this one thing, before any inspection of the wound it self, suspect by a probable conjecture, that the skull is broken, and perswade the beholders or standers by so much.

Moreover we may, before we have cut the skin across, or laid bare the bone, give a guess by our feeling, whether the skull be broken, or no, if we by pressing down our fingers neer the wound shall perceive the bone either to stand up, or be pressed down otherwise than it should naturally be.

The skin being cut crosswise and the bone laid bare, if the fracture be not obvious to the eye, you must try with your probe, which must neither be too thin nor too sharp, lest by falling into some naturall cranies, it may cause us to suspect without any cause that the bone is broken; neither let it be too thick, lest the little clifts may deceive you. If when your probe comes to the bone, it meets with nothing but that which is smooth and slippery, it is a sign that it is whole.

But on the contrary if you find it any thing rough, specially where there is no suture, it shews the bone is broken. But let the Chirurgeon consider, that the fractures are not seldom upon the sutures; and that the sutures have not alwayes one and their naturall site; as also it often comes to pass that the broken cleft, or cut bone can neither be perceived by your sight, nor instrument; wherefore if you think there is any such thing, by the rationall signs above mentioned; anoint the place with writing Inke, and oyl, and so you shall find the crack or clift, by the means we shall shew you hereafter.

When you are certain of the fracture, then you must diligently consider the greatness of the disease, and apply medicines speedily. Verily when a fracture chanceth to light upon any suture, the disease is hard to be known, unless the fracture be very great, because the sutures by their clifts and roughness resemble fractures; wherefore *Hippocrates* saith that he was deceived by them. Now having briefly delivered the differences and signs of a broken skull, it is time to come to the severall kinds thereof, with a Fissure.

Sensible signs
of a broken
skull before
the dividing of
the skin.

crates was de-
ceived by the
sutures;*

CHAP. IIII.

Of a Fissure, being the first kind of a broken Skull.

TH the Chirurgeon by the forementioned signs shall know that the skull is broken, or cracked, and if the wound made in the musculous skin shall not be thought sufficient for ordering the fissure, then must he shave off the hair, and cut with a razour, or incision knife, the musculous skin with the *Pericranium* lying under it, in a triangular or quadrangular figure to a proportionable bigness, alwayes shunning as much as in him lyes, the sutures and temples; neither must he fear any harm to ensue hereof; for it is far better to bare the bone by cutting the skin, then to suffer the kind & nature of the fracture to remain unknown, by a too religious preservation of the skin; for the skin is cured without any great ado, though pluckt off to no purpose.

For it is much more expedient (in *Hippocrates* opinion) to cure diseases safely and securely, though not speedily, than to do it in a shorter time with fear of relapse and greater inconveniencies. Let this dissection be made with a razour, or sharp knife, and if there be any wound made in the skin by the weapon, let one of your incisions be made agreeable thereto.

A Razour, or Incision Knife.

A 2

Now

Upon what
occasion the
hairy scalp
must be cut

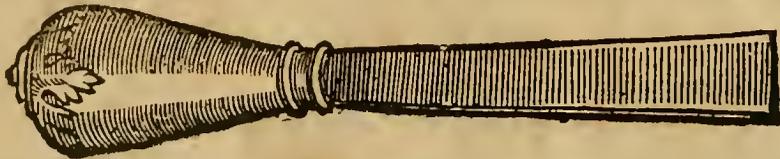

Celsus.

Hippocrates;

The manner
how to pull
the hairy scalp
from the bro-
ken skull.

Now therefore the Musculous skin together with the *Pericranium* must be divided and cut with a sharpe razour pressed and guided with a strong and stedy hand; then it must be so pluckt from the bone, or skull lying under it, that none thereof remain upon the bone; for if it should be rent or torn with the Trepan, it would cause vehement pain with inflammations. You must begin to pull it back at the corners of the lines crossing each other with right angles, with this Chissell whose figure you see here expressed.

A Chissell or Instrument to pull back or separate the Pericranium from the skull.

Then you must fill all the wound with bouldsters of fine soft lint, that for the lips may be kept further a sunder. But you shall apply upon it medicines fit to stanch blood. But if it come so to pass that the blood flows forth so violently, that it can be stayed by no means, the vessell it self must be bound, after this manner.

The manner
to bind a ves-
sell in case of
too much
bleeding.

First thrust through the musculous skin on the outside with a needle and thred, then thrust the needle back again; then tye the thred on a knot on the outside, but first put some lint rolled up to the bigness of a Goose quill between the thred and the hairy scalp on both sides thereof, lest the strait twitching of of the thred which may serve to stay the bleeding, may cut and tear the skin, or cause pain: then must you raise his head somewhat higher.

A History.

I have lately tried, and performed this upon a certain Coach-man, who thrown from the Coach upon his head on a pavement of free stone, exceedingly bruised the hind part of the *Bregma*, for which cause it was fit to open the musculous skin, with a cross incision, both that the congealed blood might be pressed out, as also that the fracture (if there were any) might be observed. But an Artery being cut in performance hereof, when as the Chirurgion who was there present could not stay the blood leaping out with violence; and the Coachman already had lost so great a quantity thereof, that his strength was so much decayed, that he could not stir himself in his bed, or scarce speak: I being called, shewed them by experience, that whereas astringent medicines were used before to no purpose, it was better to stay the bleeding by binding the vessell, than to let the Patient dye for a childish fear of pricking him.

A way to find
a fracture in
the skull,
when it pre-
sents not it
self to the
view at the
first.

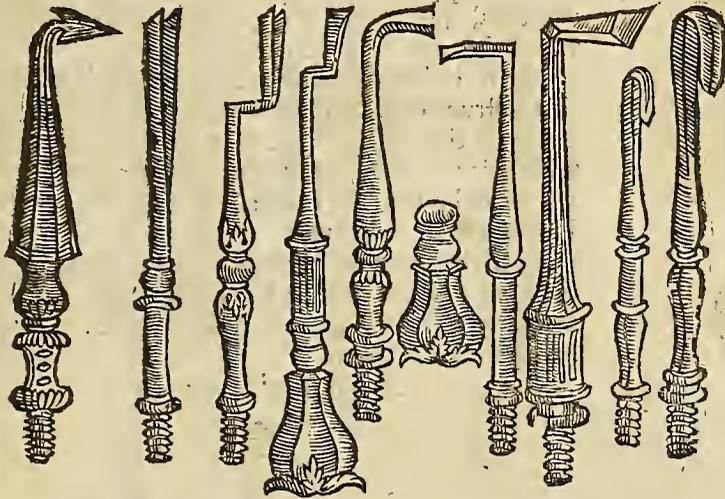

But that we may return to our former matter, the Chirurgion shall the next day consider with what kind of fracture the bone is hurt; and if no signs of hurt appear to the eyes, nor be perceived with your fingers and probe, yet some of the rationally signs may cause one to have a conjecture that there is a fracture: Then you must anoint as we told you before, the bared done with writing Ink, and a little oyl of Roses; that the cleft or crack may be dyed or coloured therewith, if that there be any there. Then the next dressing you must dry the bone with a linnen cloth, and scrape off the Ink, and oyl, with scraping Instruments made for the purpose; if any part thereof shall be sunk into the bone; for if there be any crack, it will be black; Wherefore you must continue scraping untill no sign of the fissure remain, or else untill you come even to the *Dura Mater*. But that he may be more certain whether the fissure pierce through both the Tables of the skull, he must bid the Patient, that stopping his nose and mouth, he strive to breath with a great indeavour. For then bloody matter or *Sanies* will sweat through the fissure: For the breath driven forth of the chest, and prohibited passage forth, swells and lifts up the substance of the brain, and the *Meninges*, whereupon that frothy humidity and *Sanies* sweats forth. Therefore then the bone must be cut even to the *Dura Mater*, with *Radula* and other scraping Instruments, fit for that purpose, yet so as you hurt not the membrane; but if the fissure shall be somewhat long, it will not be convenient to follow it all the extent thereof: for nature will repair and restore the remnant of the fissure by generating a *Callus*; besides also the Chirurgion according to *Celsus* opinion must take away as little of the bone as he can, because there is nothing so fit to cover the brain, as the skull. Therefore it shall suffice to make a passage, whereby the blood and *Sanies* may pass and be drawn forth, lest that matter being suppressed may corrupt the bone, and cause an inflammation in the brain. But the broken bone must be taken forth within three dayes if it be possible, especially in Summer, for fear of inflammation. Yet I have often taken forth with a Trepan and with Scrapers the bones of the skull, after the seventeenth day, both in Winter and Summer; and that with happy success. Which I have the rather noted, lest any should at any time, suffer the wounded to be left destitute of remedy: for it is better to try a doubtfull remedy than none: Yet the By-standers shall be admonished and told of the danger, for many more dye who have not the broken bones of the skull taken out, than those that have.

A sign that
both the Ta-
bles are bro-
ken.

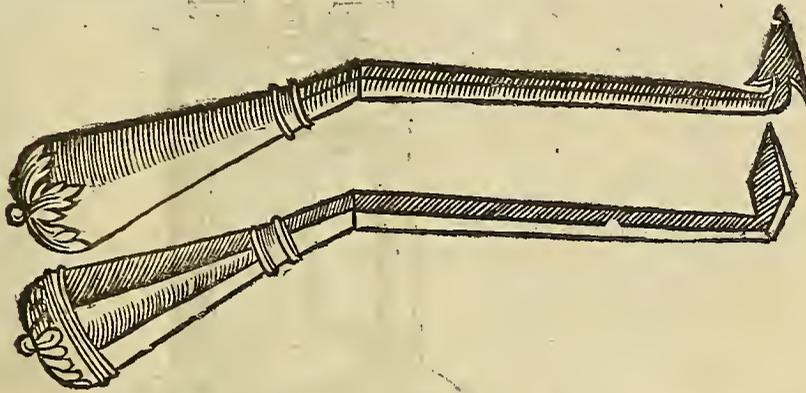

You may use
the Trepan
after the tenth
day.

But the Instruments, with which the wounded or cleft bones may be cut out are called *Scalpri* or *Radulae*, of which I have caused divers sorts to be here decyphered, that every one might take his choice, according to his mind, and as shall be best for his purpose. But all of them may be scrued into one handle, the figure whereof I have exhibited.

Radulae or *Scalpri*, (i) *Shavers or Scrapers*.

Radulae of another form, for the better cutting of the greater bones.

To conclude, when the skull shall be wounded or broken with a simple fissure, the Chirurgion must think he hath done sufficient to the Patient, and in his Art, if he shall divide the bone and dilate the fissure or cleft with the described Instruments, though he have used no Trepan, although the fissure pierce through both the Tables. But if it doth not exceed the first Table, you must stay your scrapers as soon as you come to the second, according to the opinion of *Paulus*: but if the bone shall be broken & shivered into many peeces, they shall be taken forth with fit Instruments, using also a Trepan if need shall require, after the same manner as we shall shew you hereafter.

It is sufficient in a simple fissure to dilate it with your *Scalpri* only and not to Trepan it.

CHAP. V.

Of a Contusion, which is the second sort of fracture.

AN *Ecchymosis*, that is, effusion of blood, presently concreting under the musculous skin, without any wound, is oft caused by a violent contusion. This Contusion if it shall be great, so that the skin be divided from the skull, it is expedient, that you may make an incision, whereby the blood may be evacuated and emptied. For in this case you must wholly desist from suppurative medicines (which otherwise would be of good use in a fleshy part) by reason that all the moist things are hurtfull to the bones, as shall be shown hereafter.

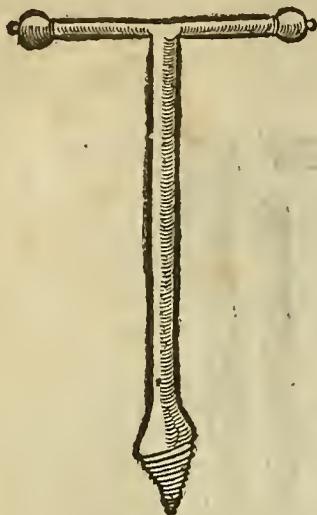

What an *Ecchymosis* is.

Such like Contusions more frequently happen in children, being easily perceived by the softness, and inundation of the contused part: forth of which oft-times when I have opened them with my incision knife, serous, clotted and blackish blood hath issued. The residue of the cure is perfected by moderate compression of the part, and drying medicines. Moreover the skull of a child, may be pressed down, by a great contusion, even as we see it happens in thin vessels of brass, lead, or pewter, for oft-times by the pressure of your finger, they are so dented in, that the print thereof remains; yet sometimes they fly back of themselves, and again acquire their former plainness and equability, which also happens in the bones of children, women and such as are soft, humid, & phlegmatick. But if the bones do not spring back of themselves, you must apply a cupping-glass with a great flame; withall command the Patient, to force his breath up as powerfully as he can, keeping his mouth and nose

How a contusion of the skull must be cured.

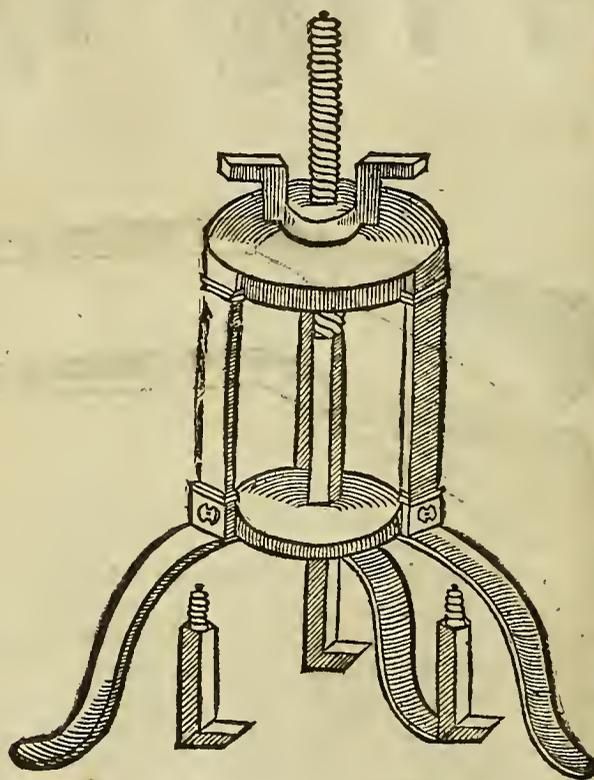

Different cures of a depressed skull.

close shut; for thus there will be hope, to restore the depressed bone to its place, by the spirits forc'd upwards to the brain and skull, by the powerfull attraction of the cupping-glass. But if so be that the bone cannot by this means be restored, then you must make an incision in the skin, and fasten such a Trepan, as you see here delineated, into the depressed, or settled part of the bone, and so pull it directly upwards, just as we see Coopers raise the staves of their cask, when they are sunk too much in.

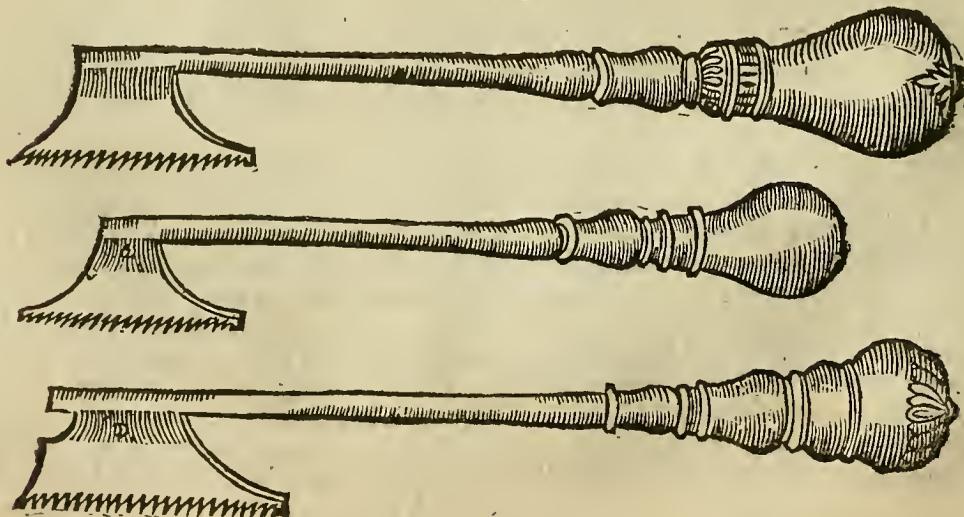

But if the bone shall be too strong, thick, and dense, so that this Instrument will not serve to pluck it forth; then you must perforate the skull, in the very center of the depression, and with this threefold Instrument, or Levatory put into the hole, lift up and restore the bone to its naturall site; for this same Instrument is of strength sufficient for that purpose. It is made with three feet, that so it may be applyed to any part of the head which is round; but divers heads may be fitted to the end thereof according as the business shall require, as the figure here placed doth shew.

A three footed Levatory.

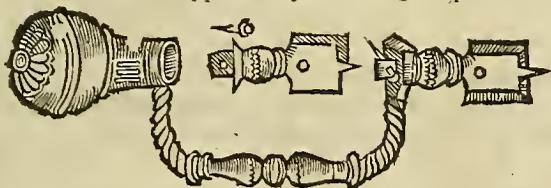

But if at any time it comes to pass, that the bone is not totally broken or depressed, but only on one side; it will be fit, so to lift it up, as also to make a vent for the issuing out of the filth, to divide the skull with little saws like these, which yee see here expressed; for thus so much of the bone, as shall be thought needfull, may be cut off without compression, neither will there be any danger of hurting the brain or membrane with the broken bone.

The figures of Saws fit to divide the skull.

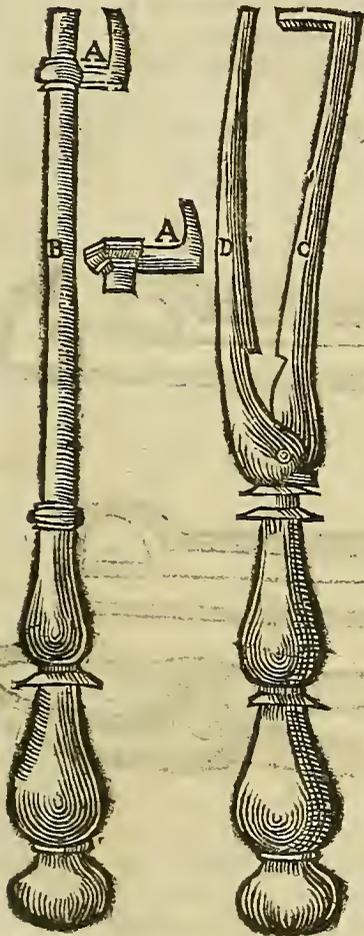

But if by such signs as are present, and shall appear, we perceive or judge that the contusion goes but to the second Table, or scarce so far; the baring or taking away of the bone, must go no further than the contusion reaches; for that will be sufficient to eschew and divert inflammations and divers other symptoms. And this shall be done with a scaling or Desquamatory Trepan, (as they term it) with which you may easily take up as much of the bone, as you shall think expedient: And I have here given you the figure thereof.

A Desquamatory or Scaling Trepan.

A delineation of other Levatories.

A A. Shews the point or tongue of the Levatory, which must be somewhat dull, that so it may be the more gently and easily put between the Dura Mater and the skull, and this part thereof may be lifted up so much by the head or handle taken in your hand, as the necessity of the present operation shall require.

B. Intimates the body of the Levatory, which must be four square, lest the point, or tongue put thereon should not stand fast, but the end of this Body must rest upon the sound bone, as on a sure foundation.

The use thereof is, thus; put the point or tongue under the broken or depressed bone, then lift the handle up with your hand, that so the depressed bone may be elevated.

C. Shews the first Arm of the other Levatory, whose crooked end must be gently put under the depressed bone.

D. Shews the other Arm, which must rest on the sound bone, that by the firm standing thereof, it may lift up the depressed bone.

CHAP. VI.

Of an Effraction, depression of the bone, being the third kind of Fracture.

BEfore I come to speak of an Effraction, I think it not amiss to crave pardon of the courteous and understanding Reader, for this reason especially, that as in the former Chapter, when I had determined and appointed to speak of a Contusion, I inserted many things of a Depression; so also in this chapter of an Effraction, I intend to intermingle something of a Contusion; we do not this through any ignorance of the thing it self; for we know that it is called a Contusion, when the bone is depressed and crushed, but falls not down. But an Effraction is when the bone falls down and is broken by a most violent blow. But it can scarce come to pass, but that the things themselves must be confounded and mixt, both as they are done; and also when they are spoken of: so that you shall scarce see a Contusion without an Effraction, or this without that. Therefore the bones are often broken off and driven down with great and forcible blows, with clubs whether round or square, or by falling from a high place directly down, more or lesse according to the force of the blow, kind of weapon, and condition of the part receiving the same: Wherefore you must be provided with diversity of remedies and instruments to encounter therewith. Wherefore admit the bone is pressed down, and shivered into many pieces, now for that these splinters need not be taken out with a Trepan, you may do the business with Levatories made and neatly fashioned for that purpose; such as these, which are here exprest.

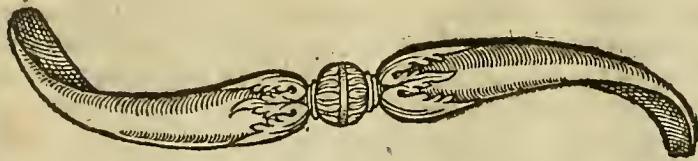

What a contusion is.

What an Effraction is.

The cause of Effractions.

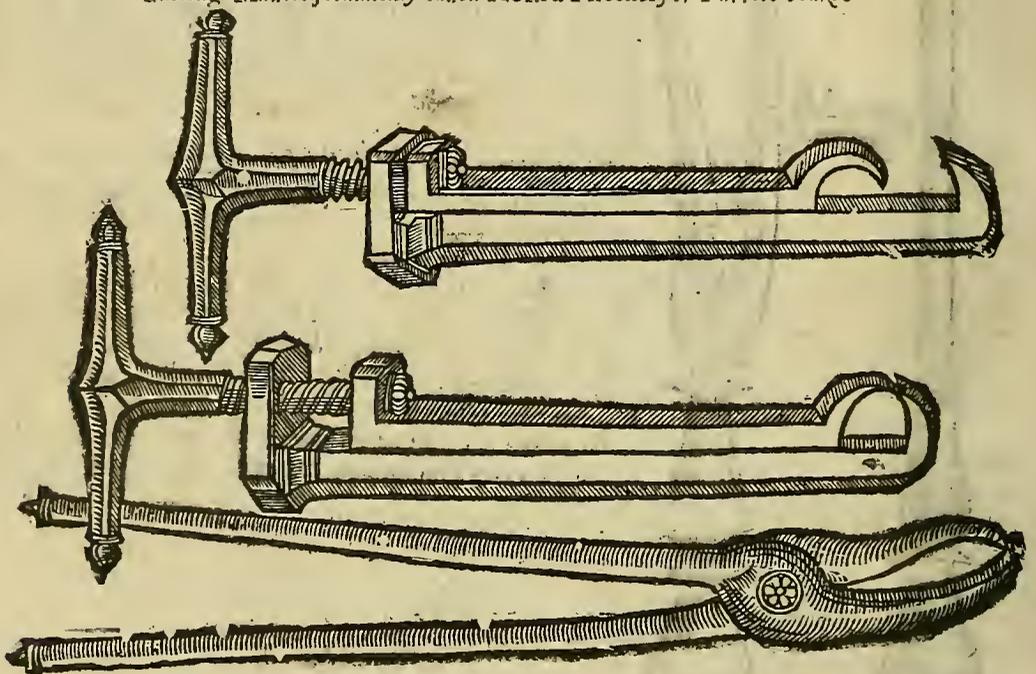

The cures

A Levatorie.

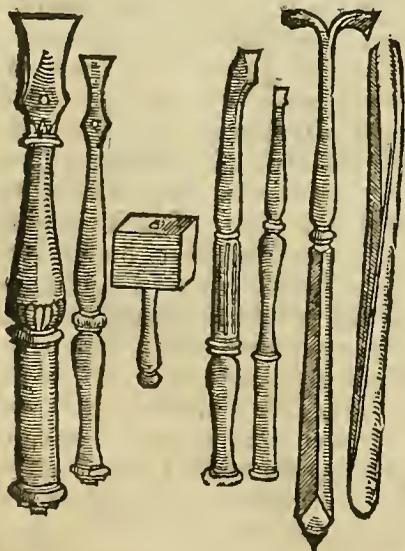

But we must have special care, lest that in pulling and taking out of these scales and splinters, we hurt the membranes. These scales are sometimes very rough and prickly, so that they cannot touch the *Meninges* without offence; but somewhiles the business is so intricate, that they cannot be taken out unless by enlarging the fracture. Wherefore in this case, if there be a space so large, as that the ends of these mallets may enter, you may easily shear off so much of the bone as shall be necessary and requisite for the taking away of these scales, without any assistance of the Trepan, which I have done very often and with good success; for the operation performed by these mallets is far more speedy and safe, than that with the Trepan; and in the performance of every operation, the chief commendation is given to safeness and celerity.

Cutting Mallets, commonly called *Rostrum Psittaci*, or Parrots beaks.

Moreover I have thought good here to give you the figures of chissels, scrapers, pincers, together with a leaden mallet, because such instruments are not only very necessary to take forth the scales of bones which are broken, but also to plain and smooth those which remain whole.

The Figures of Scrapers, Pincers, a leaden mallet, &c.

But here you must note, that a Trepan, nor Levatorie, must never be applied to a bone quite broken, lest the membranes lying under it be hurt by the compression thereof. Therefore you must apply them to a sound bone, but as near as you can to the fracture, so that you take away as little of the skull as is possible, lest the brain despoiled of its bony cover; take some harm thereby. Neither effractions, nor yet fissures, if they be of some length; must be followed to their ends, but think your self well, if you have made a passage for the issuing forth of the *Sanies* or filth, & have drawn forth that bone, which pricked the membranes. For nature is accustomed by generating a *Callus* to foulder, or unite the bones of the skull, as it also doth thereof the other parts; as we have read it written by *Hippocrates* and *Galen*; for which purpose it hath by singular providence replenished both the tables of the skull, with a certain alimentary and bloody matter, that with this as with marrow it might repair the loss and defect of the bone.

The

The truth hereof was lately manifested in the servant of Master *Grolo*, who had an Effra-
cture on the coronall bone, by a grievous blow, given him with the foot of a Mule; which
when I understood, I divided the musculous skin with a three cornered section in that place;
with an intent to apply a Trepan there; wherefore the day following, the bone being bo-
red, and when I thought to draw it forth, yea verily endeavoured to pluck it forth, being
already divided with the Trepan, I perceived a fearefull production of an Effracture; by
the moveableness of the bone shaking under my hand; for it reached from the midst of the
forehead, to the lesser corner of the eye. Wherefore omitting both my determination and
endeavour to pull it forth, I thought I should do sufficiently for the patient, if I should on-
ly raise up the bone which was deprest; for so it did not trouble the *Crassa meninx* by pres-
sing it, and the matter, and filth, were let forth by a passage made with a saw. So that in con-
clusion, he recovered perfectly, but that he lost one of his eyes which was adjoining to the
fracture.

A History.

CHAP. VII.

Of a Seat, being the fourth kind of a broken Scull.

Hippocrates calls a Seat that kind of Fracture of the scull, when the weapon so falls
upon the scull, that the fracture retaining the print thereof, is neither stretched
forth any further, nor contracted to any lesse space.

What a Seat is;

And seeing there be many forms hereof, they all whether they shall be super-
ficiary, or shall pierce even to the *Diploe*, or else pass through both the Tables,
whether it be with any loss of the bony substance, whether it run long wayes, or else be but
short; or otherwise are dilated to some breadth, or else be but narrow; whether they shall
be done with a cut, or with a prick with a dagger, styletto, lance or other kind of weapon,
whether they shall have this or that accident joined with them, I say all of them, how ma-
ny and various soever they be, ought and must be cured by some of the formerly described
Instruments and means. Yet this must be noted, which as yet we have not remembred, that
if it happen by a violent stroak, & great wound, that a portion of the bone is wholly so cut
off, that it is clean severed from the rest of the scull, and hang only by the *Pericranium* and
musculous skin; yet you must not pluck it from the *Pericranium*, and cast it away as unpro-
fitable, but restore it to its proper seat and place, so by the force of nature, to be glewed by
a *Callus*, as *Celsus* hath observed.

The cure;

Lib. 8. cap. 2.

I have tryed the truth of this experiment, in captain *Hydron*, not very long agoe. He had
the middle part of the *Os Coronale*, of the bredth, and length of three fingers, so cut with a
sharp sword, that it stuck not to the rest of the bone; but scarce adhering to the *Pericranium*
and musculous skin; but lay turned down over his face, so that the *Dura Mater* was plainly
seen; wherefore I prepared to pluck it from the skin, and cast it away, but that I remembred
Hippocrates precept, where he bids, that the Brain should not be robbed of its cover and left
bare. Wherefore first of all I wiped away the blood which was fallen upon the *Dura Mater*;
whose motion you might plainly see, then I restored the portion of the bone to its place,
and fastned it on the upper side with a suture consisting of three stiches; and that the resi-
due of the matter might have passage forth, I filled the places between each stitch with lint;
by this means, he by the mercie of God recovered, though at the same time he received many
other large wounds in his body; which is a certain experiment, that we must cast away no
part of the scull, nor of the *Pericranium*, no not of the musculous skin, unless necessity urge;
therefore much less to leave the brain naked and despoiled of its coverings.

A History.

CHAP. VIII.

Of a Resonitus, or Counter-fissure, being the fifth kind of Fracture.

Sometimes the fracture is made in the part opposite to that which received the
blow; as if the right side be struck, the left is cloven; this kind of fracture is very
dangerous, because we cannot find it out by any certain sign, as it is written by
Hippocrates Lib. de vuln. Capitis. Wherefore if at any time the patient dye of such a
fracture, the Chirurgion must be pardoned.

What a Resonitus is.

And although *Paulus Aegineta* laugh at this kind of fracture and thinks that it cannot
happen to a mans head, as that which is hard and full, as it happens in empty glass bottles,
yet I have sometimes seen and observed it.

Lib. 6. cap. 90.

Neither is their reason of any validity, who think nature therefore to have framed the head
of many bones knit together by sutures, lest the fracture of the one side, should be stretch-
ed to the other. For peradventure this may take place, in such as have expresse sutures, seated
and framed according to nature. But it takes no place in such as either want them, or have
them not seated according to nature, or have them very close and so defaced that it may
seem one bone growne together of many; This shall be made manifest by recital of the fol-
lowing Historie.

In whom this fracture may take place in divers bones of the Scull.

A servant of *Massus* the Post-master had a grievous blow with a stone, upon the right
Bregma,

A History.

Bregma, which made but a small wound, yet a great contusion and Tumor. Wherefore that it might more plainly appear, whether the bone had received any harme, and also that the congealed blood might be pressed forth, the wound was dilated, the skin being opened by *Theodore Hereus* the Chirurgeon, who as he was a skillfull workman and an honest man, omitted nothing which Art might do for his cure. When he had divided the skin, the bone was found whole, although it was much to be feared, that it was broken, because he fell presently to the ground with the blow, vomited and shewed other signes of a fractured scull; so it happened that he dyed on the one and twentieth day of his sicknes. But I being called to learn, and search how he came by his death, dividing the scull with a saw, found in the part opposite to the blow, a great quantity of *Sanies* or bloody matter, and an Abscess in the *Crassameninx*, and also in the substance of the very brain, but no sutures, but the two scaly ones. Therefore that is certain which is now confirmed by the authority of *Hippocrates*; as also by reason and experience, that a blow may be received on the one side, and the bone may be fractured on the opposite, especially in such as have either no sutures, or else so firmly united and closed, that they are scarce apparent.

The *Resonius* may be in the same bone of the scull.

A History.

Neither is it absurd, that the part, opposite to that which received the stroak, of the same bone and not of divers bones may be cloven, and in those men who have their sculls well made, and naturally distinguished and composed with sutures; and this both was, and is, the true meaning of *Hippocrates*. That this may be the better understood, we must note that the opposite part of the same bone may be understood two manner of ways. First, when the fracture is in the same surface of the smitten bone, as if that part of one of the bones of the *Bregma* which is next to the *Lambdall* future be smitten, and the other part next to the *Coronall* future be cloven. Secondly, when as not the same superficies and table which receives the blow, but that which lyes under it is cleft, which kind of fracture I observed, in a certain Gentleman a Horsman of Captain *Stempans* troop; He in defending the breach of the wall of the Castle of *Hisdin* was struck with a Musket bullet upon the *Bregma*, but had his helmet on his head; the bullet dented in the helmet but did not break it, no nor the musculous skin, nor scull, for as much as could be discerned, yet notwithstanding he died apoplectick upon the sixth day after.

But I being very desirous to know, what might be the true cause of his death, dividing his scull; observed that the second table was broken, and cast off scales and splinters, wherewith as with needles the substance of the brain was continually pricked, the first and upper table being whole, for all this: I afterwards shewed the like example to *Capellanus* and *Castellanus* the King and Queens chief Physitians in the expedition of *Roane*.

Why *Hippocrates* sets set downe no way to cure a *Resonius*.

The manner to know when the scull is stasford by a *Resonius*.

But *Hippocrates* prescribes no method of curing this sixth kind of fracture, by reason he thinks it cannot be found out by any circumstance, whence it happens that it is for the most part deadly: Yet must we endeavour to have some knowledg and conjecture of such a fracture, if it shall at any time happen. Wherefore having first diligently shaven away the haire, we must apply an Emplaster of Pitch, Tar, Wax, Turpentine, the powder of *Iris*, or flower deluce roots, and massich; now if any place of the head shall appeare more moist, soft and swoln, it is somewhat likely that the bone is cleft in that place, so that the Patient, though thinking of no such thing, is now and then forced to put his hand to that part of the scull. Confirmed with these and other signs formerly mentioned, let him call a counsell of learned Physitians; and foretell the danger to the Patients friends which are there present, that there may no occasion of calummie remain, then let him boldly perforate the scull; for that is far better, than forsake the Patient ready to yeeld to the greatnes of the hidden disease, and so consequently to dye within a short while after. There are foure sorts, or conditions of fractures, by which the Chirurgeon may be so deceived, that when the scull is broken indeed, yet he may think there is no fracture. The first is when the bone is so depressed, that it presently rises up into its true place, and native equability. The second is when the fissure is only capillary. The third is when the bone is shaken on the inside, the utter surface nevertheless remaining whole, forasmuch as can be discerned. The fourth is, when the bone is stricken on the one side and cleft on the other.

CHAP. IX.

Of the moving, or Concussion, of the Brain.

Gal. lib. 2. de comp. medic. cap. 6. & Com. ad Aph. 58. sect. 7.

Besides the mentioned kinds of fractures by which the brain also suffers; there is another kind of affect besides nature, which also assailes it by the violent incurfion of a cause, in like manner, externall; they call it the Commotion or shaking of the brain, whence Symptomes like those of a broken scull ensue. Falling from aloft upon a solid and hard body, dull and heavy blows, as with stones, clubs, staves, the report of a peece of Ordnance, or crack of Thunder, and also a blow with ones hand.

Lib. 5. Epidem.

Thus as *Hippocrates* tells, that beautifull damosell the daughter of *Nerius*, when she was twenty yeeres old, was smitten by a woman, a friend of hers, playing with her, with her flat hand upon the fore part of the head, and then she was taken with a giddines, and lay without breathing, and when she came home, she fell presently into a great Feaver, her head

aked,

aked, and her face grew red. The seventh day after there came forth some two or three Ounces of stinking and bloody matter about her right eare, and she seemed somewhat better and to be at somewhat more ease. The feaver increased again, and she fell into a heavy sleepiness, and lost her speech, and the right side of her face was drawn up, and she breathed with difficulty, she had also a convulsion and trembling; both her tongue failed her, and her eyes grew dull, on the ninth day she died. But you must note, that though the head be armed with a helmet, yet by the violence of a blow, the Veines, and Arteries may be broken, not only these which pass through the sutures, but also those which are dispersed between the two tables in the Diploe, both that they might bind the *Crassa meningis* to the skull, that so the brain might move more freely, as also that they might carry the alimentary juyce to the brain wanting marrow, that is, blood to nourish it, as we have formerly shewed in our Anatomie.

But from hence proceeds the efflux of blood running between the skull, and membranes, or else between the membranes and brain; the blood congealing there, causeth vehement pain, and the eyes become blind, vomiting is caused, the mouth of the stomach suffering together with the brain, by reason of the Nerves of the sixth conjugation, which run from the brain thither, and from thence are spread over all the capacity of the ventricle; whence becoming a partaker of the offence it contracts it self, and is presently as it were overturned; whence first, these things that are contained therein are expelled, and then such as may flow, or come thither from the neighbouring and common parts, as the Liver and Gall; from all which cholera, by reason of its naturall levity and velocity, is first expelled and that in greatest plenty; and this is the true reason of that vomiting, which is caused and usually followes upon fractures of the skull and concussions of the brain.

Within a short while after inflammation seizes upon the membranes and brain it self, which is caused by corrupt and putrid blood proceeding from the vessels broken by the violence of the blow, and so spread over the substance of the brain. Such inflammation communicated to the heart, and whole body by the continuation of the parts, causes a feaver. But a feaver, by altering the brain causes Doting; to which if stupidity succeed, the Patient is in very ill case, according to that of *Hippocrates*; Stupidity, and doting, are ill in a wound, or blow upon the head. But if to these evils, a sphacell, and corruption of the brain ensue, together with a great difficulty of breathing, by reason of the disturbance of the Animall faculty, which from the brain imparts the power of moving to the muscles of the Chest, the instruments of respiration, then death must necessarily follow.

A great part of these accidents appeared in King *Henry* of happy memory, a little before he dyed. He having set in order the affaires of France, and entred into amitie with the neighbouring Princes, desirous to honour the marriages of his daughter, and sister, with the famous and noble exercise of Tilting, and he himself running in the Tilt-yard, with a blunt lance received so great a stroak upon his brest, that with the violence of the blow, the visour of his helmet flew up, and the trunchion of the broken Lance hit him above the left eye-brow, and the musculous skin of the forehead was torn even to the lesser corner of the left eye, many splinters of the same; trunchion being struck into the substance of the fore mentioned eye, the bones being not touched or broken; but the brain was so moved and shaken, that he dyed the eleventh day after the hurt. His skull being opened after his death, there was a great deal of blood found between the *Dura*, and *Pia Mater*, poured forth in the part opposite to the blow, at the middle of the future of the hind part of the head; & there appeared signs by the native colour turned yellow, that the substance of the brain was corrupted, as much as one might cover with ones thumb. Which things caused the death of the most Christian King, and not only the wounding of the eye, as many have falsely thought. For we have seen many others, who have not dyed of farre more grievous wounds in the eye.

The history of the Lord Saint *Iohns* is of late memory; he in the Tilt-yard, made for that time before the Duke of *Guises* house, was wounded with a splinter of a broken Lance, of a fingers length and thicknesse, through the visour of his Helmet, it entring into the Orbe under the eye, and piercing some three fingers bredth deep into the head; by my help and Gods favour he recovered, *Valerianus* and *Duretus* the Kings Physitians and *James* the Kings Chirurgeon assisting me.

What shall I say of that great and very memorable wound of *Francis* of *Lorraine* the Duke of *Guise*? He in the sight of the City of *Bologne* had his head so thrust through with a Lance, that the point entring under his right eye by his nose, came out at his neck between his ear and the *Vertebre*, the head or Iron being broken and left in by the violence of the stroak, which stuck there so firmly, that it could not be drawn or plucked forth, without a pair of smiths pincers. But although the strength and violence of the blow was so great, that it could not be without a fracture of the bones, a tearing and breaking of the Nerves, Veines, Arteries and other parts; yet the generous Prince by the favour of God recovered.

By which you may learn, that many dye of small wounds; and other recover of great, yea, very large and desperate ones. The cause of which events is chiefly and primarily to be attributed to God, the author and preserver of mankind; but secondarily to the

variety and condition of temperaments. And thus much of the commotion or concussion of the brain; whereby it happens that although all the bone remains perfectly whole, yet some veins broken within by the stroak, may cast forth some blood upon the membranes of the brain, which being there concrete may cause great pain, by reason whereof it blinds the eyes; if so be that the place can be found against which the pain is, and when the skin is opened, the bone look pale, it must presently be cut out, as *Celsus* hath written. Now it remains, that we tell you how to make your prognosticks, in all the forementioned fractures of the skull.

CHAP. X.

Of Prognosticks to be made, in fractures of the skull.

Hip. de vul. cap.

E must not neglect any wounds in the head, no not these which cut or bruise but only the hairy scalp; but certainly much less, these which are accompanied by a fracture in the skull; for oft-times all horrid symptoms follow upon them, and consequently death it self, especially in bodies full of ill humors, or of an ill habit, such as are these which are affected with the *Lues venerea*, leprosie, dropsie, Pthisick, consumption, for in these, simple wounds are hardly or never cured; for union is the cure of wounds, but this is not performed, unless by the strength of nature, and sufficient store of laudable blood: but those which are sick of hec tick feavers and consumptions, want store of blood, and those bodies which are repleat with ill humors, and of an ill habit, have no afflux or plenty of laudable blood: but all of them want the strength of nature; the reason is almost the same in those also which are lately recovered of some disease.

Whether the wounds of children, or old people are better to heal.

Those wounds which are bruised are more difficult to cure, than those which are cut. When the skull is broken, then the continuity of the flesh lying over it must necessarily be hurt and broken, unless it be in a *Resonitus*. The bones of children are more soft, thin, and replenished with a sanguine humidity, than those of old men, and therefore more subject to putrefaction; Wherefore the wounds which happen to the bones of children, though of themselves, and their own nature they may be more easily healed, (because they are more soft, whereby it comes to pass, that they may be more easily agglutinated, neither is there fit matter wanting for their agglutination by reason of the plenty of blood laudable both in consistence and quality) than in old men, whose bones are dryer and harder, and so resist union, which comes by mixture, and their blood is ferous, and consequently a more unfit bond of unity and agglutination; yet oft-times through occasion of the symptoms which follow upon them, that is, putrefaction and corruption, which sooner arise in a hot and moist body, and are more speedily encreased in a soft and tender, they usually are more suspected and difficult to heal.

The Patient lives longer of a deadly fracture in the skull, in Winter than in Summer, for that the native heat is more vigorous in that time than in this; besides, also the humors putrefie sooner in Summer, because unnaturall heat is then easily inflamed and more predominant, as many have observed out of *Hippocrates*.

Aph. 15. sect. 1.

The wounds of the brain and of the *Meninges* or membranes thereof are most commonly deadly, because the action of the muscles of the chest, and others serving for respiration, is divers times disturbed and intercepted, whence death insues. If a swelling happening upon a wound of the head presently vanish away, it is an ill sign, unless there be some good reason therefore, as blood-letting, purging, or the use of resolving locall medicines, as may be gathered by *Hippocrates* in his Aphorisms. If a feaver insue presently after the beginning of a wound of the head, that is, upon the fourth or seventh day, which usually happens, you must judge it to be occasioned by the generating of *Pus* or Matter, as it is recited by *Hippocrates*. Neither is such a feaver so much to be feared, as that which happens after the seventh day, in which time it ought to be terminated; but if it happen upon the tenth or fourteenth day with cold or shaking, it is dangerous, because it makes us conjecture that there is putrefaction in the brain, the *Meninges*, or skull, through which occasion it may arise, chiefly if other signs shall also concur, which may shew any putrefaction, as if the wound shall be pallid and of a faint yellowish colour, as flesh looks after it is washed.

Aphor. 65. sect. 5.

Aph. 47. sect. 2.

Wounds which are dry, rough, livid and black are evil.

For, as it is in *Hippocrates* Aphorif. 2. sect. 7. It is an ill sign if the flesh look livid, when the bone is affected; for that colour portends the extinction of the heat, through which occasion, the lively, or indifferently red colour of the part, fairs and dyes, and the flesh thereabout is dissolved into a viscid *Pus* or filth.

Commonly another worse affect follows hereon, wherein the wound becoming withered and dry, looks like salted flesh, sends forth no matter, is livid and black, whence you may conjecture, that the bone is corrupted, especially if it become rough, whereas it was formerly smooth and plain; for it is made rough when *Caries* or corruption invades it; but as the *Caries* increases, it becomes livid and black, sanious matter with all sweating out of the *Diploe*, as I have observed in many: all which are signs that the native heat is decayed, and therefore death at hand; but if such a feaver be occasioned from an *Erysipelus* which is either present or at hand, it is usually less terrible. But you shall know by these signs, that the feaver is caused by an *Erysipelus* and conflux of cholerick matter; if it keep the form of a Ter-
tian

The signs of a feaver caused by an *Erysipelus*.

tian, if the fit take them with coldness and end in a sweat; if it be not terminated before the cholericke matter is either converted into Pus or else resolved; if the lips of the wound be somewhat swollen, as also all the face; if the eyes be red and fiery; if the neck and chaps be so stiffe, that he can scarce bend the one, or open the other; if there be great excess of biting and pricking pain, and heat, and that far greater than in a Phlegmon. For such an Erysipelous disposition generated of thin and hot blood, chiefly assails the face, and that for two causes.

The first is, by reason of the naturall levity of the cholericke humor; the other because of the rarity of the skin of these parts.

The cure of such an affect must be performed by two means, that is, evacuation, and cooling with humectation. If cholera alone, cause this tumor, we must easily be induced to let blood, but we must purge him with medicines evacuating cholera. If it be an Erysipelas phlegmonodes, you must draw blood from the Cephalick vein of that side, which is most affected; always using advise of a Physitian. Having used these generall means, you must apply refrigerating and humecting things, such as are the juyce of Night-shade, Housleek, Purslane, Lettuce, Navell wort, Water Lentill, or Ducks-meat, Gourds; a liniment made of two handfuls of Sorrell boyled in fair water, then beaten or drawn through a sarse, with oymment of Roses, or some unguent. Populeon added thereto, will be very commodious. Such and the like remedies must be often and so long renewed untill the unnaturall heat be extinguished. But we must be carefull to abstain from all unctuous and oily things, because they may easily be inflamed, and so increase the disease. Next we must come to resolving medicines; but it is good when any thing comes from within, to without; but on the contrary it is ill, when it returns from without inwards, as experience and the Authority of Hippocrates testifie: If when the bone shall become purulent, pustules shall break out on the tongue; by the dropping down of the acrid filth or matter by the holes of the palat upon the tongue, which lyes under. Now when this symptom appears, few escape. Also it is deadly when one becomes dumb and stupid, that is, Apoplectick by a stroak or wound on the head; for it is a sign that not only the bone, but also the brain it self is hurt. But oft-times the hurt of the Brain proceeds so far, that from corruption it turns to a Sphacell, in which case, they all have not only pustules on their tongues, but some of them dye stupid and mute, other some with a convulsion of the opposite part; neither as yet have I observed any which have dyed with either of these symptomes, by reason of a wound in the head, who have not had the substance of their brain tainted with a Sphacell, as it hath appeared when their skulls have been opened after their death.

Why an Erysipelas chiefly assails the face. The cure of an Erysipelas on the face.

Why oily things must not be used in an Erysipelas of the face. Aph. 25. sect. 6.

Deadly signs in wounds of the head.

CHAP. XI.

Why, when the brain is hurt by a wound of the head, there may follow a Convulsion of the opposite part.

Many have to this day enquired, but as yet as far as I know it hath not been sufficiently explained, why a convulsion in wounds of the head seizes on the part opposite to the blow. Therefore I have thought good to end that controversie in this place. My reason is this, that kind of Symptom happens in the sound part by reason of emptiness and dryness; but there is a twofold cause, and that wholly in the wounded part, of this emptiness and dryness of the sound or opposite part; to wit, pain and the concurrence of the spirits and humors thither by the occasion of the wound, and by reason of the pains drawing and natures violently sending help to the afflicted part.

The sound part exhausted by this means both of the spirits and humors, easily falls into a Convulsion.

For thus Galen writes; God the Creator of nature, hath so knit together, the triple spirituous substance of our bodies, with that tye, and league of concord, by the productions of the passages; to wit of Nerves, Veins, and Arteries, that if one of these forsake any part, the rest presently neglect it, whereby it languisheth; and by little and little dyes, through defect of nourishment. But if any object that nature hath made the body double, for this purpose, that when one part is hurt, the other remaining safe and sound, might suffice for life and necessity: but I say, this axiom hath no truth in the vessels and passages of the body. For it hath not every where doubled the vessels, for there is but one only vein, appointed for the nourishment of the brain, and the membranes thereof, which is that they call the Torcular, by which when the left part is wounded, it may exhaust the nourishment of the right and sound part, and though that occasion cause it to have a convulsion, by too much dryness; Verily it is true, that when in the opposite parts, the muscles of one kind are equal in magnitude, strength, and number, the resolution of one part, makes the convulsion of the other by accident; but it is not so in the brain.

For the two parts of the brain, the right and left, each by its self performs that which belongs thereto, without the consent, conspiracy or commerce of the opposite part; for otherwise it should follow, that the Palsie properly so called, that is of half the body, which happens by resolution, caused either by mollification or obstruction residing in either part of the brain, should infer together with it a Convulsion of the opposite part. Which notwithstanding dayly experience convinces as false. Wherefore we must certainly think;

A convulsion is caused by dryness.

A twofold cause of convulsifick dryness.

Lib. 4. de usu partium.

think, that in wounds of the head wherein the brain is hurt, that inanition and want of nourishment are the causes, that the sound and opposite part suffers a convulsion.

Opinion of
Dalechampius

Francis Dalechampius in his French Chirurgery renders another reason of this question; That, (saith he) the truth of this proposition may stand firm and ratified, we must suppose, that the convulsion of the opposite part mentioned by *Hippocrates*, doth then only happen, when by reason of the greatness of the inflammation in the hurt part of the brain, which hath already inferred corruption, and a Gangrene to the brain and men-branes thereof, and within a short time is ready to cause a sphacell in the skull, so that the disease must be terminated by death; for in this defined state of the disease, and these conditions, the sense and motion must necessarily perish in the affected part, as we see it happens in other Gangrens, through the extinction of the native heat. Besides, the passages of the animall spirit must necessarily be so obstructed by the greatness of such an inflammation or phlegmon, that it cannot flow from thence to the parts of the same side lying there under, and to the neighbouring parts of the brain; and if it should flow thither, it will be unprofitable to carry the strength and faculty of sense and motion, as that which is infected and changed by admixture of putrid and Gangrenous vapours. Whereby it cometh to pass, that the wounded part destitute of sense, is not stirred up to expell that which would be troublesome to it, if it had sense; wherefore neither are the Nerves thence arising seized upon, or contracted by a Convulsion.

It furthermore comes to pass, that because these same nerves are deprived of the presence and comfort of the animall spirit, and in like manner the parts of the same side, drawing from thence their sense and motion are possessed with a palse; for a palse is caused either by the cutting or obstruction of a Nerve, or the madefaction, or mollification thereof by a thin and watry humor, or so affected by some vehement distemper, that it cannot receive the Animall spirit.

But for the opposite part and the convulsion thereof, it is known and granted by all, that a convulsion is caused either by repletion which shortens the Nerves by distending them into breadth, or by inanition, when as the native and primitive heat of the Nerves being wasted, their proper substance becoming dry is wrinkled up and contracted; or else it proceeds from the vellication, and acrimonie of some vapour, or sanious and biting humor, or from vehemency of pain. So we have known the falling sickness caused by a venenate exhalation carried from the foot to the brain. Also we know that a convulsion, is caused in the puncture of the Nerves, when as any acrid and sanious humor is shut up therein, the orifice thereof being closed; but in wounds of the Nerves when any Nerve is half cut, there happens a convulsion by the bitterness of the pain.

But verily in the opposite part, there are manifestly two of these causes of a convulsion; that is to say, a putrid and carionlike vapour, exhaling from the hurt, and Gangrenate part of the brain; and also a virulent, acrid and biting *Sanies*, or filth, sweating into the opposite sound part, from the affected and Gangrenous; the malignity of which *Sanies*, *Hippocrates* desirous to decipher, in reckoning up the deadly signs of a wounded head, hath expressed it by the word *Ichor*; and in his book of fractures he hath called this humor *Dacryodes et non Pyon*. [that is, weeping and not digested.] Therefore it is no marvail if the opposite and sound part endued with exquisite and perfect sense, and offended by the flowing thereto of both the vaporous and sanious matter, using its owne force, contend and labour as much as it can, for the expulsion of that which is troublesome thereto. This labouring or concussion is followed (as we see in the falling sickness) by a convulsion, as that which is undertaken in vain, death being now at hand; and nature over-ruled by the disease. Thus (saith *Dalechampius*) must we in my judgement determine of that proposition of *Hippocrates* and *Avicen*.

But he addes further, in wounds of the head, which are not deadly, practitioners observe that sometimes the hurt part is taken with the palse, and the sound with a convulsion; otherwhiles on the contrary, the wounded part is seized by a Convulsion and the sound by a Palse; otherwhiles both of them by a convulsion or Palse, and somewhiles the one of them by a convulsion or Palse, the other being free from both affects; the causes of all which belong not to this place to explain. Thus much *Dalechampius*.

CHAP. XII.

A Conclusion of the deadly signs in the Wounds of the head.

The signes of
a deadly
wound from
the depraved
faculties of the
minde.

Now that we may returne to our former discourse; you may certainly foretell the patient will dye; when his reason and judgement being perverted, he shall talke idly; when his memory fails him; when he cannot governe his tongue; when his sight growes dark and dim, his ears deaf, when he would cast himself headlong from his bed, or else lyes therein without any motion; when he hath a continuall feaver with a *delirium*; when the tongue breaks out in pustles, when it is chopt, and become black, by reason of too much dryness; when the wound grows dry, and casts forth little or no matter; when as the colour of the wound which was formerly fresh, it now become like salted

From habite
of the body.

salted flesh yellow and pale; when the Urine, and other excrements suppress; when the palse, convulsion, apoplexie; and lastly, often sowning, with a small and unequall pulse, invade him. All such signs sometimes appear presently after the wound, otherwhiles some few dayes after; therefore when as the brain is hurt and wounded by the violence of the incision, or fissure, of the contusion, compression, puncture, concussion, or any other fracture, the forementioned signs appear presently in the first dayes; but when they do not appear til many dayes after the blow, you may know that they rise and appear, by reason of an inflammation and phlegmon in the brain, occasioned by the putrefaction of the blood poured forth upon it.

From the time that such signs appear.

But we must observe this by the way, which also belongs to the prognosticks, that flesh is easily regenerated, and restored in all parts of the head, except in that part of the forehead, which is a little above that which lies between the eye-brows, so that it will be ulcerated ever after, and must be covered with a Plaister. I beleve that in that place there is an internall cavity in the bone, full of air, which goes to the five-like bones of the nose, by which the growth of flesh may be hindered; or else that the bone is very dense or compact in that place, so that there can scarce sufficient juice sweat forth, which may suffice for the regeneration of flesh; add hereunto a great conflux of excrements flowing to this ulcer, which should otherwise be evacuated by the eyes and nose, which hinder by that means the dryness of the ulcer, and consequently the healing thereof.

Celsus lib. 8. cap. 4.

Hence certainly it comes to pass, that if you desire the Patient thus affected to breath, shutting his mouth and nose, the air or breath will come forth of the ulcer with such force, as it will easily blow forth a lighted candle of an indifferent bigness held thereto. Which thing I protest, I observed in a certain man, whom I was forced to trepan in that place, by reason the bone of the forehead was broken and depressed.

CHAP. XIII.

Of salutary signs in wounds of the head.

BUt on the contrary these are salutary signs, when the Patient hath no fever, is in his right mind, is well at the application or taking of any thing, sleeps well, hath his belly soluble, the wound looks with a fresh and lively colour, casts forth digested and laudable matter, the *Crassa Meninx* hath its motion free and no way hindered.

Yet we must note, which also is observed by the Ancients and confirmed by experience, that we must think none past danger, and free from all chance, untill the hundredth day be past. Wherefore the Physitian ought so long to have a care of his Patient, that is, to consider how he behaves and governs himself in meat, drink, sleep, venery and other things.

When the Patients are out of danger.

But let the Patient diligently avoid and shun cold, for many when they have been cured of wounds of the head, by careless taking cold have been brought into danger of their lives. Also you must know that the *Callus* whereby the bones of the skull are knit together, requires almost the space of forty or fifty dayes to its perfect coagmentation and concretion. Though in very deed one cannot set down a certain number of dayes, by reason of the variety of bodies, or tempers: For it is sooner finished in young men, and more slowly in old; And thus much may serve for prognosticks. Now will we treat as briefly and perspicuously as we can of the cure both in generall and particular; wherefore beginning with the generall we will first prescribe a convenient diet by the moderate use of the six things not naturall.

The Patient must beware of cold.

CHAP. XIII.

Of the generall cure of a broken skull, and of the Symptomes usually happening thereupon.

THe first cure must be, to keep the Patient in a temperate air; and if so be, that it be not such of it self and its own proper nature, it must be corrected by Art. As in winter he must have a clear fire made in his chamber, lest the smoak cause sneezing and other accidents; and the windows and doors must be kept shut to hinder the approach of the cold air and wind. All the time the wound is kept open to be dressed, some body standing by

How the air ought to be.

shall hold a chafendish full of coals or a heated Iron bar over the wound, at such a distance, that a moderate heat may pass thence to the wound; and the frigidity of the encompassing air may be corrected by the breathing of the diffused heat. For cold according to the opinion of *Hippocrates*, is an enemy to the Brain, Bones, Nerves, and spinal marrow; it is also hurtfull to ulcers, by suppressing their excrements, which suppress do not only hinder suppuration, but also by corrosion makes them sinuous. Therefore *Galen* rightly admonisheth us, to keep cold from the brain, not only in the time of trepanning, but also afterwards. For there can be no greater, nor more certain harm befall the fractured skull, than by admitting the air, by such as are unskillfull. For if the air should be hotter than the brain, then it could not thence be refrigerated; but if the brain should be laid open to the air, in the midst of summer, when it is at the hottest, yet would it be refrigerated; and unless it were relieved with hot things, take harm: this is the opinion of *Galen*, whereby you may understand that many who have their skulls broken, dye more through default of skill in the curing, than by the greatness of the fracture.

Apher. 18. §.

Lib. 2. de usu part.

cap. 2. The Air though in summer is colder than the brain.

But (when the wound is bound up with the pledgets, cloths, and rowlers, as is fit) if the air chanced to be more hot, than the Patient can well indure, let it be amended by sprinkling, and strawing the chamber with cold water, oxycrate, the branches of Willows and Vine. Neither is it sufficient to shun the too cold air, unless also you take heed of the over light, chiefly untill such time as the most feared and malign symptomes are past.

For a too great light dissipates the spirits, increases pain, strengthens the fever and symptomes. *Hippocrates* wholly forbids wine, therefore the Patient instead thereof must drink Barly water, fair water boyled and tempered with Julep of Roses, syrup of Violets, vinegar and the like: water where-

The disorders of too much light.

What his drink must be. in bread crums have been steeped, water and sugar with a little juyce of Lemons, or pomecitron added thereto, and such like as the ability and taste of the Patient shall require. Let him continue such drinks untill he be free from malign symptoms, which usually happen within fourteen dayes.

Almonds increase the pain of the head. His meat shall be pap, ptisan, shunning Almond milks; (for Almonds are said to fill the head with vapours and cause pain) stued damask Prunes, Raisons and currants, seasoned with sugar, and a little cinnamon (which hath a wonderfull power to comfort the stomach, and revive and exhilarate the spirits) Chickens, Pidgeons, Veal, Kid, Liverets, birds of the fields, Pheasons, black-birds, Turtles, Partridges, Thrushes, Larks and such like meats of good digestion, boiled with lettuce, purslain, sorrell, borage, bugloss, succory, endive and the like, are thought very convenient in this case. If he desire at any time to feed on these meats roasted, he may only dipping them in verjuice, in the acid juices of Oranges, Citrons, Lemons, or Pomegranats, sometimes in one, and sometimes in another, according to his tast and ability. If any have a desire to eat fish, he must mak choyce of Trouts, Gudgeons, Pikes and the like, which live in running and clear waters, and not in muddy; he shall eschew all cold sallets and pulse, because they fly up and trouble the head: it will be convenient after meat to use common dridg powder, or Aniseed, Fennellseed or Coriander comfits, also conserve of Roses, or Marmilate of Quinces to shut up the orifice of the Ventricle, lest the head should be offended with vapours arising from thence.

What fish he may eat. Children must eat often, but sparingly; for children cannot fast so long as those which are elder, because their naturall heat is more strong, wherefore they stand in need of more nourishment; so also in winter all sorts of people require more plentifull nourishment, for that then their stomachs are more hot than in Summer.

Aphor. 13. & 14. sect. 1. When the foureteenth day is past, if neither a fever, nor any thing else forbid, he may drink wine moderately, & by little and little, encrease his diet, but that respectively to each ones nature, strength and custome. He shall shun, as much as in him lyes, sleep on the day time, unless it happen that a *Phlegmon* seise upon the brain or *Meninges*. For in this case it will be expedient to sleep on the day time, especially from morning till noon, for in this season of the day, as also in the spring blood is predominant in the body, according to the opinion of *Hippocrates*. For it is so vulgarly known, that it need not be spoken, that the blood when we are awake is carried into the habit and surface of the body; but on the contrary by sleep it is called into the noble parts, the Heart and Liver. Wherefore if that the blood by the force of the Sun casting his beams upon the earth at his rising is carryed into the habit of the body, should again be more and more diffused by the strength & motion of watching, the inflammation in the brain and *Meninges* would be much encreased. Wherefore it will be better, especially then to stay by sleep the violence of the blood running into the habit of the body, when it shall seem to rage and more violently to affect that way. Watching must in like manner be moderate; for too much depraves the temper of the brain and of the habit of the whole body; it causes crudities, pains and heaviness of the head, and makes the wounds dry and maligne.

Why sleep upon the day time is good for the brain being inflamed. Lib. 2. Epidem. The commodities insuing immoderate Watching. Gal. Meth. 18. Medicines procuring sleep. The commodities of sleep. But if the Patient cannot sleep by reason of the vehemency of the inflammation of the brain and *Meninges*, *Galen* wilhes, to wash, besmear and anoint the head, nose, temples and ears with refrigerating and humecting things, for these stupefie, and make drowsie the Brain and membranes thereof, being more hot than they ought to be. Wherefore for this purpose let the temples be anointed with *Vnguentum populeon*, or *Vnguentum Rosatum* with a little rose vinegar, or oxycrate; let a sponge moistened in the decoction of white or black poppie seed, of the rinds of the roots of Mandrages, of the seeds of Henbane, lettuce, purslane, plantain, night-shade and the like. He may also have a broath or barley cream, into which you may put an emulsion made of the seeds of white Poppy, or let him have a potion made with ζ i, or ζ i β , of the syrup of poppy, with ζ ij, of Lettuce water; Let the Patient use these things 4. houres after meat, to procure sleep. For sleep doth much help concoction, it repairs the efflux of the triple substance caused by watching a swageth pain, refresheth the weary, mitigates anger and sorrow, restores the depraved reason, so that for these respects it is absolutely necessary that the Patient take his naturall rest.

If the Patient shall be plethorick, let the plenitude be lessened by blood-letting, purging and a slender diet, according to the disertation of the Physitian who shall oversee the cure. But we must take heed of strong purgations, in these kinds of wounds, especially at the beginning, lest the fever, inflammation, pain, and other such like symptoms be increased by stirring up the humors.

Lib. 4. meth. Phlebotomy, according to *Galen*s opinion, must not only be made respectively to the plenty of blood, but also agreeable to the greatness of the present disease, or that which is to come, to divert, and draw back that humor which flows down, by a way contrary to that which is impact in the part; and which must be there evacuated, or drawn to the next. Wherefore for example, if the right side of the head be wounded, the Cephalick vein of the right arm shall be opened, unless a great *Plethora* or plenitude cause us to open the *Basilica*, or Median, yet if neither of them can be fitly opened, the *Basilica* may be opened, although the body is not plethorick. The like course must be observed in wounds of the left side of the head; for that is far better by reason of the straitness of the fibers, than to draw blood on the opposite side; in performance whereof you must have diligent care of the strength of the Patient, still feeling his pulse, unless a Physitian be present, to whose judgment you must then commit all that business. For the pulse is, in *Galen*s opinion, the certainest shewer of the strength. Wherefore we must consider the changes and inequalities thereof, for as soon as we find it to become lesser and more slow, when the forehead begins to sweat a little, when he feels a pain at his heart, when he is taken with a desire to vomit, or go to stool, or with yawning, and when he shall change his colour and his lips look pale, then you must stop the blood as speedily as you can; otherwise there will be danger lest he poure forth his life together with his blood. Then he must be refreshed with bread steeped in wine, and put into his mouth, and by rubbing his temples and nostrils with

with strong vinegar, and by lying upon his back. But the part shall be eased and freed from some portion of the impact and conjunct humor by gently scarifying the lips of the wound, or applying of Leeches. But it shall be diverted, by opening these veins which are nearest to the wounded part, as the *Vena puppis*, or that in the midst of the forehead, or of the temples, or these which are under the tongue; besides also cupping-glasses shall also be applyed to the shoulder sometimes, with scarification, sometimes without; neither must strong, and long frictions, with course clothes, of all the whole body, the head excepted, be omitted during the whole time of the cure, for these will be available, though but for this; that is, to draw back and dissipate by insensible transpiration the vapours which otherwise would ascend into the head, which matters certainly in a body that lyes still and wants both the use and benefit of accustomed exercise, are much increased.

The use of Fractures.

But it shall be made manifest by this following and notable example; how powerfull blood-letting is, to lessen and mitigate the inflammation of the Brain, or the membranes thereof in wounds of the head. I was lately called into the suburbs of Saint German, there to visit a young man twenty eight yeeres old, who lodged there in the house of *John Martiall*, at the sign of Saint *Michaell*. This young man, was one of the household servants of Master *Doucador*, the steward of the Lady *Admirall* of *Erion*. He fell down headlong upon the left *Bregma*, upon a marble pavement, whence he received a contused wound, without any fracture of the skull, and being he was of a sanguin temperature, by occasion of this wound, a feaver tooke him on the seventh day with a continuall *delirium* and inflammation of phlegmonous tumor of the wounded *Pericranium*. This same tumor possessing his whole head and neck by continuation and sympathy of the parts, was grown to such a bigness, that his visage was so much altered, that his friends knew him not; neither could he speak, heare, or swallow any thing but what was very liquid. Which I observing, although I knew, that the day past, which was the eight day of his disease, he had foure saucers of blood taken from him by *Germaine Agate* Barber-surgeon of the same suburbs; yet considering the integrity and constancy of the strength of the Patient, I thought good to bleed him again; wherefore I drew from him fourteen saucers at that one time; when I came to him the day after, & saw that neither the feaver, nor any of the fore mentioned symptoms were any whit remitted, or asswaged, I forthwith took from him foure saucers more, which in all made two and twenty; the day following when I had observed, that the symptoms were no whit lessened, I durst not presume by my own only advice, to let him the fourth time blood as I desired. Wherefore I brought unto him, that most famous Physitian Doctor *Violene*, who as soon as he felt his pulse, knowing by the vehemency thereof, the strength of the Patient, and moreover considering the greatness of the inflammation & tumor which offered it self to his sight, he bid me presently take out my Lancet and open a vein. But I lingred on set purpose, and told him, that he had already twenty two saucers of blood taken from him. Then said he, Grant it be so, and though more have been drawn, yet must we not therefore desist from our enterprise, especially seeing the two chiefe Indications of blood-letting yet remain, that is, the greatness of the disease, and the constant strength of the Patient. I being glad of this, tooke three saucers more of blood, he standing by, and was ready to take more but that he wished me to defer it untill the after noon; wherefore returning after dinner I filled two saucers more, so that in all, this young man to his great benefit, lost twenty seven saucers of blood at five times, within the space of foure dayes. Now the ensuing night was very pleasing to him, the feaver left him about noon, the tumor grew much lesse, the heat of the inflammation was asswaged in all parts, except in his eyelids, and the laps of his ears, which being ulcerated cast forth a great quantity of Pus or matter. I have recited this history purposely, to take away the childish feare which many have to draw blood in the constant strength of the Patient, and that it might appear how speedy and certain a remedy it is in inflammations of the head and brain.

A History.

The two chief Indications in blood-letting.

Now to return from whence we digressed, you must note that nothing is so hurtfull in fractures and wounds of the head, as venery; not only at that time the disease is present, but also long after the cure thereof. For great plenty of spirits are contained in a small quantity of seed, and the greatest part thereof flows from the brain; hence therefore all the faculties, but chiefly the Animall, are resolved, whence I have divers times observed death to ensue in small wounds of the head, yea when they have been agglutinated and united. All passions of the mind must in like sort be avoided, because they by contraction and dissipation of the spirits cause great trouble in the body and mind. Let a place be chosen for the Patient as far from noise as can be, as from the ringing of bells, beatings and knockings of Smiths, Coopers, and Carpenters, and from high-ways through which they use to drive Coaches; for noise encreases pain, causes a feaver, and brings many other symptoms.

The discommoditie of venery in wounds of the head.

How hurtfull noyse is to the fractures of the skull.

I remember when I was at *Hisdin* at the time that it was besieged by the forces of *Charles* the fifth, that when the wall was beaten with the Cannon, the noise of the Ordnance caused grievous torment to all those which were sick, but especially those that were wounded on their heads, so that they would say; that they thought at the discharging of every Cannon that they were cruelly stricken with staves on that part which was wounded, and verily their wounds were so angred herewith, that they bled much, and by their pain and feavers encreased, were forced with much sighing to breath their last. Thus much may serve to be spoken of the cure in generall, now we will out of the monuments of the ancients, treat of the particular.

A History.

CHAP. XV. Of the particular cure of wounds of the head, and of the musculous skin.

Let us begin with a simple wound, for whose cure the Chirurgeon must propose one only scope, to wit, Union; for unlesse the wound pierce to the skull, it is cured like other wounds of the fleshy parts of our bodies. But if it be compound, as many wayes as it is complicate, so many indications shew themselves. In these the chiefe care must be had of the more urgent order and cause,

Of a simple wound of the fleshy and the skin.

Therefore if the wound shall be simple and superfiary, then the haire must first be shaven away, then a plaister applyed made of the white of an egge, bole Armenick and Aloes. The following day you must apply *Emplastrum de Ianua* or else *de gratia Dei*, untill the wound be perfectly healed. But if it be deeper and penetrate even to the *Pericranium*, the Chirurgeon shall not do amiss, if at the second dressing he apply a digestive medicine (as they call it) which may be made of Venice Turpentine, the yolks of egges, oyl of Roses, and a little Saffron, and that shall be used so long, untill the wound come to maturation; for then you must add honey of Roses and Barly floure to the digestive. Hence must we pass to these medicines, into whose composition no oyle or unctuous bodie enters, such as this; *R. Terebinth. venet. ʒ ij, Syrupi rosar. ʒ j, pul. aloes, Myrrh. & mastich. an. ʒ β*. Let them all be incorporated and made into an unguent, which shall be perfectly regenerated, then it must be cicatrized with this following powder. *R. Aluminis combusti, corticis granatorum combust. ʒ an ʒ j, Miscantur simul & fiat pulvis*: but if the wound be so large that it require a suture, it shall have so many stiches, with a needle, as need shall seem to require.

The cure of
the Hairy
scalp when
it is contu-
sed.

A repelling
medicine.

Whilst I was at *Hisdin*, a certain souldier, by falling of the earth whilst he undermined, had the Hairy scalp so pressed down even to the *Pericranium*, and so wholly separated from the beginning of the hind part of his head, even to his forehead, that it hung over his face. I went about the cure in this manner; I first washt all the wound with wine, a little warmed, that so I might wash away the congealed blood mixed with the earth; then I dryed it with a soft linnen cloth, and laid upon it Venice-Turpentine mixed with a little *Aqua-vitæ* wherein I had dissolved some *Sanguis Draconis*, *Mastick* and *Aloes*; then I restored the hanging skin to its former place, and there staid it with some stiches, being neither too strait, nor too close together, for fear of pain and inflammation, (which two chiefly happen whilst the wound comes to suppuration) but only as much as should serve to stay it on every side, and to keep forth the air, which by its entrance doth much harm to wounds: the lower sides of the wound, I filled with somewhat long and broad tents, that the matter might have passage forth. Then I applyed this following cataplasim to all the head. *R. farinæ bord. & fabarum an. ʒ vi. olei rosati, ʒ iij, aceti quantum sufficit, fiat cataplasma ad formam pultis*; this hath a faculty to dry, cool, repell, mitigate pain and inflammation and stay bleeding.

I did not let him bleed, because he had bled much, especially at certain arteries which were broken near his temples; he being dressed after this manner grew well in a short time. But if the wound be made by the biting of a wild beast, it must be handled after another manner, as shall appear by this following history. As many people on a time stood looking upon the Kings Lyons, who were kept in the Tilt-yard at *Paris*, for the delight of King *Henry* the second, and at his charges: it happened that one of the fiercest of them broke the things wherein he was tyed, and leaping amongst the company, he with his paws threw to the ground a Girl of some twelve yeers old, and taking her head in his mouth, with his teeth wounded the musculous skin in many places, yet hurt not the skul. She scarce at length delivered by the Master of the Lyons from the jaws of Death and the Lyon, was committed to the cure of *Rowland Claret* Chirurgeon; who was there present by chance at the same time; some few dayes after, I was called to visit her; she was in a fever, her head, shoulders, breast, and all the places where the Lyon had set his teeth, or nails, were swollen, all the edges of the wound were livid, and did flow with a waterish, acrid, virulent, cadaverous, dark green and stinking matter, so that I could scarce indure the smell thereof; she was also oppressed with pricking, biting and very great pain; which I observing, that old saying came into my mind, which is: That all wounds made by the bitings of beasts, or of men also, do somewhat participate of poyson. Wherefore there must principally great care be had of the venenate impression left in the wounds by the nails & teeth, and therefore such things must be applyed, as have power to overcome poyson. Wherefore I scarified the lips of the wounds in divers places, and applyed Leeches to suck out the venenate blood, and ease the inflammation of the parts, then I made a Lotion of *Ægyptiacum* Treacle and Mithridate after the following manner.

R. Mithrid. ʒ j, theriac. ʒ ij, ægyptiac. ʒ β, dissolvantur omnia cum aqua vitæ, & Cardui ben. Let the wounds be fomented and washed with it warm; besides also Treacle and Mithridate were put in all the medicines which were either applyed or put into the wound; and also of the same with the conserves of Roses and Bugloss dissolved in the water of Sorrell and *Carduus benedictus*, potions were made to strengthen the heart and vindicate it from malign vapors.

For which purpose also this following *Epithema* was applyed to the region of her heart. *R. aquæ rosar. & nenuphar, an. ʒ iij, aceti scillitici ʒ j, corallorum, santalorum alborum & rubrorum, rosar. rub. pulveris, spodi. an. ʒ j, Mithridatii, theriacæ an. ʒ ij, flo. cordial. pulveris atorum p. ij, croci ʒ j*, dissolve them all together, make an Epitheme and apply it to the heart with a scarlet cloth or sponge, and let it be often renewed. Verily she drest after this manner, and the former remedies but once used, pain, inflammation and all the malign symptomes were much lessened; to conclude, shee recovered, but lingered and was lean some two yeers after, yet at length she was perfectly restored to her health and former nature. By which you may understand, that simple wounds must be handled after another manner, than these which have any touch of poison.

But now that we may prosecute the other affects of the hairy scalp; say that it is contused with a blow without a wound, that which must be first and alwayes done, (that so the affect may better appear, and the remedies which are applyed may take more effect) the hair must be shaven away, and at the first dressing a repelling medicine applyed, such as this following *Oxyth odinum*. *R. ol. ros. ʒ iij, album ovorum nu. ij, pulveris nucum cypressi, balaust. alumin. rochæ. rosar. rub. an. ʒ j*. Let them be all incorporated, and make a medicine for the former use, or in stead thereof you may apply the cataplasim prescribed before consisting of *Farina hordei, fabarum, aceto & oleo rosaceo*. But such medicines must be often renewed. When the pain and defluxion are appeased, we must use discussing medicines for dissipation of that

that humor which remains impacted in the part; R^e Emplastri de mucilag. ℥ij. oxicrocei, & emp. de melilo-
to, an. ℥j. olei chamem. & anethi, an. ℥β. malaxentur simul et fiat emplastrum ad usum dictum. Such a fomentation
will also be good. R^e vini rub. lib. iij. lixivii. com. lib. ij. nuces cupressi contus. nu. x. pul. myrtillorum ℥j. rosar. rub.
absinth. fol. salvia. major ane. st. echados. florum chamem. melil. an. M. β. aluminis rocha. radices cyperi, calami aromatici
an. ℥β. bulliant omnia simul, and make a decoction to foment the grieved part. After somewhat a long
fomenting it, whereby it may the better discusse, dry and exhaust the concrete humor, the head must
be dried and more discussing things applycd, such as the Cerate described by Vigo called de minio;
which hath an emollient and digestive facultie in this form. R^e Olei chamem. lilior. an. ℥x. olei mastich. ℥ij.
pinguedinis vervecis lib. j. litharg. auri, ℥vii. minii ℥ij. vini boni cyathum unum, bulliant omnia simul baculo agi-
tando, primum quidem lento igne, mox vero luculentiore, donec tota massa colorem nigrum vel subnigrum contrahat;
adde in fine cocturae Terebinth. lib. s. pulveris mastich. ℥ij. gum. elemi. ℥j. cera quantum sufficit, bulliant rursus una
ebullitione & fiat empl. molle. But if the humor be not thus discussed, but onely grow soft, then the tu-
mor must be quickly opened, for when the flesh is inflamed and putrefied through occasion of the
contained humor, the bone under it putrefies also by the contagion of the inflammation and the acri-
mony of the matter falling upon the bone. When you have opened it, wash away the filth of the ul-
cer with this following deterfive medicine. R^e syrapi ros. & absinth. an. ℥j. terebinth. ℥β. pul. ireos, aloes, ma-
stichis, myrrh. & farine bordei an. ℥β. In stead hereof if there be great putrefaction, *Aegyptia* either by it
selfe, or mixt with an equall quantity of *Vnguentum apostolorum* may be put into the ulcer. When the
ulcer is clenfed it will be time to use scarotick and cicatrizing medicines.

C H A P. XVI. Of the particular cure of a fracture or broken skull.

F the skull be broken, so that it be needfull to trepan it, or to elevate and lift it up, or scrape
it away, the musculous skin being cut as we formerly noted, the *Pericranium* shall be pluck-
ed from the skull, as we said before; which because it can hardly be done without great
pain, by reason of its exquisite sense and connexion with the membranes of the braine, we
must labour to mitigate the paine for feare of inflammation and other accidents. Therefore the first
dressing ended & the corners of the wound drawn each from other; at the second dressing put to the
wound, a digestive (as they terme it) made of the yolk of an egge, and oyle of Roses, but you must
apply no humid thing to the bone, because we desire to keep it found and whole. For *Galens* opini-
on is, that bared bones must not be touched with unctuous things; but rather on the contrary, all
dry things must be applyed to them, which may consume the superfluous humidity. Therefore we
must lay some lint and the cephalick powders which we shall hereafter describe, upon the bone we
intend to preserve, and must have diligent care that it be not offended either by the ayre, or touch of
humid medicines. You must in Trepaning have a speciall care of the *Crassa meninx*. For I have often
observed a great quantity of blood to have flowed from some broken vessell, which adhered to the
second Table: neither must we presently and forthwith stay such bleeding, but suffer it to flow ac-
cording to the plenitude and strength of the patient; for thus the fever, and together therewith
the rest of the symptomes are diminished. For the opinion of *Hippocrates*, in every green wound it is
good to cause often bleeding, except in the bellies; for thus the vehemency of pain, inflammation and
other accidents will be less troublesome; also it is not amisse too for old ulcers to bleed much, for
so they are freed from the burden of the impact humors. When you think it hath bled sufficiently,
it may be stanchd with this following medicine described by *Galen*:

Why the
Pericran-
ium hath

Gal. 6. meth.

R^e pulveris Aloes ℥ij. thuris mastiches, an. ℥β. albumina ovorum nu. ij. agitentur simul cum pilis leporinis mi-
nutim incisis, fiat medicamentum. When the bleeding is stayed, you shall for the asswaging of pain, drop
upon the *Meninx* some Pigeons blood, yet warme by opening a Vein under the wing, then it shall be
strewed over with this following powder, R^e Aloes, thuris, myrrh. & sanguinis draconis an. ℥j. Misc. fiat pulvis
subtilis. Also you may make an irrigation with Rose Vinegar, or some repelling medicine; such as
is a cataplasme ex farina, & oleo rosaceo. Which may be applyed untill the fourth day to asswage and
mitigate pain.

Vigoes Cerate will be of good use in this case, as that which in my opinion is most fit for fractures
of the skull, because it draws powerfully, resolves and dryes moderately, and by reason of the smell
refreshes the animall spirits, and strengthens the brain and membranes thereof, as you may easily per-
ceive by things which enter into the composition thereof. R^e Olei ros. Omph. resina pini, gummi Elemi,
an. ℥ij. Mastiches ℥β. pinguedinis vervecis castrati ℥ij. foliorum beton. caprifol. an. Mj. ammoniaci ℥β. gra-
norum tinctorum ℥x. liquata pinguedin eterenda terantur, & ammoniacum simul cum aceto scillitico, eliquetur;
deinde bulliant omnia simul in lib. ij. vini boni, lento igne usque ad consumptionem vini, deinde
exprimantur; cum expressione addantur terebinth. Ven. ℥iij. cera alba quantum sufficit, fiat cerotum mol-
le ad usum predictum. Also let the neck, and all the spine of the back be anointed with a liniment,
which hath force of mollifying the Nerves, lest they should suffer convulsion; such is this.

Vigoes Cer-
ate good for
a broken
skull.A liniment
good a-
gainst con-
vulsions.

R^e Ruta, marrubii, torismar. ebular salvia, herb. paralyt. an. M. s. rad. Ireos, cyperi, baccarum lauri, an. ℥j. florum
ebana. melil. hyperici, an. Mj. pistentur & macerentur omnia in vino albo per noctem, deinde coquantur in vase duplici
cum oleo lumbri-corum, liliorum, de terebinthina, axungie, ansetis & hum. an. ℥ij. usque ad consumptionem vini, postea
colentur & incelatur a adde terebinth. venet. ℥iij. aque vitæ ℥β. cera quantum sufficit fiat linimentum secundum
artem.

But when the pain is asswaged, we must abstain from all such unctuous things, lest they make the
wound become sordid and malign, and putrefie the adjacent parts, and consequently the *Crassa
meninx* and skull; for the integrity of all parts may be preserved by their like, and such are dry things
in a fracture of the skull. Wherefore all humid and oily things must be shunned in the cure there-
of, unless peradventure there shall be some need to mitigate pain & bring the humor to suppuration.

For according to *Galen*, we are oft forc'd for a time to omit the proper cure of the disease, so to

Gal. 4. meth.

How farre humid things are good for a fractured skull.

resist the symptomes; furthermore *Hippocrates* would have us not to foment the skull, no not with wine, but if we do, to let it be but with very little. *Vidius* interprets that little to be, when there is fear of inflammation; for wine if it be red, tart and astringent, hath a repressing, refrigerating and drying faculty: for otherwise all wine although it heats and dries by its faculty, yet it actually humects and cools, both which are very hurtfull in wounds of the head, or a fractured skull, especially when the bone is bare; for from too much cooling of the brain there is fear of a convulsion, or some other evill symptome. Wherefore let this be ratified, that is, We must not use humid and unctuous medicines in wounds of the head, except for curing of an inflammation, or the mitigation of pain caused thereby. Therefore let the bared skull be strewed with catagmatick and cephalick powders, (being so called by the Ancients, for that they are convenient and good in fractures of the skull and the rest of the bones) for by their dryness they consume the superfluous humidity, and by that means help nature in the separating of the broken bones, and the regenerating of flesh. Such powders usually consist of such things as these ensuing. Thus, *radix Iridos florent. farina bordei. & Ervi, pulvis Aloes Hepaticæ, sanguis Draconis, mastiche, Myrrha, rad. Aristolochiæ, Gentianæ*: and generally all such simples as have a drying and an abstergent faculty without biting; but you must not use these things before the pain, inflammation and apostumation be past; that is then, when the membranes must be clenfed, the bones sealed, and the flesh generated. For the skull by how much it is the dryer, by so much it requires and more easily endures more powerfull and dryer medicines than the *Dura Mater* or *Pericranium*, as that which in quickness of sense comes far short of these two. Wherefore when you would apply the forementioned cephalick powders to the *Meninges*, they must be associated and mixed with hony, syrup of roses or of wormwood and such other like, that so their too violently drying faculty may be allayed and tempered.

Why Cephalick or Catagmatick powders are good.

When to be used. How to be mixed when they are to be applied to the *Meninges*.

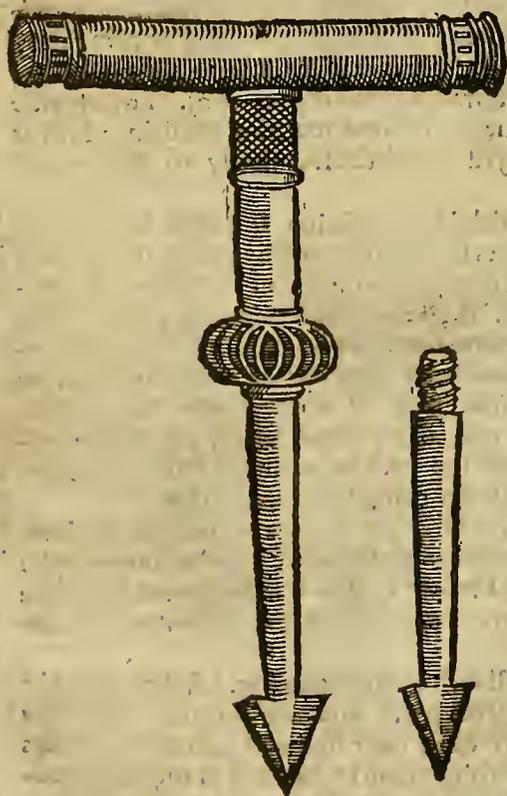

CHAP. XVII. Why we use Trepaning, in the Fractures of the Skull.

Here are four causes of this remedy: The first is, to raise up the deprest bones, and take forth their fragments, which press upon the *Meninges*, or also upon the substance of the brain. The second is, that the *Sanies* or matter may be evacuated, clenfed, wasted, and dried up, which by the breaking of any vessell is poured forth upon the Membranes, whereby they are, and not they only, but the brain also is in great danger of corruption. The third is, for the sifter application of medicines, convenient for the wound and fracture. The fourth is, that so we may have something whereby we may supply the defect of a Repelling Ligature, & such an one as may hinder defluxions; for such a Ligature cannot take place here as it may in the other parts of the body, by reason of the Sphæricall or Round figure of the head, which doth not easily admit binding; & then the density and hardness of the interposed skull is a means that the vessells lying under it (by which usually the defluxion comes) cannot easily be bound with a rowler sufficiently to repell the running blood. And the externall vessells, (to whom the force of the Ligature may come) cannot be bound without great pain, and danger of inflammation. For by such a compression the pulsation of the Arteries would be intercepted, and the efflux of the fuliginous excrements which useth to pass through the futures of the skull, would be suppressed, by reason of the constriction of these futures.

Why a repelling Ligature cannot be used in fractures of the skull.

The shape of this Instrument is not much different from a Gimblet, but that the point is three-square, and not twined like a screw; as you may perceive, by this following figure.

A Gimblet or piercer to perforate the skull, before the setting in of the Trepan.

How the patient must be placed when you Trepan him.

What to be done before the application of the Trepan.

Besides also, the blood would thus be forced from the wounded part without, to within into the Membranes and Brain; when pain, inflammation, a Fever, Abscess, Convulsion, Palsie, Apoplexie, and lastly, death it self would insue.

And these are the chief causes, that Trepaning is necessary in fractures of the skull, and not so in the fractures of other bones.

But before you apply or put to your Trepan, the Patient must be fitly placed or seated, and a double cloth must be many times wrapped about his head, and then his head must be so laid, or pressed upon a Cushion or pillow, that when you come to your operation, it may not sink down any further, but remain firm and steady. Then you must stop the Patients ears with Cotten-wooll, that so he may not hear the noise made by the Trepan or any other Instrument.

But before you put to your Trepan, the bone must be pierced with an Instrument, having a three square point, that so it may be the more speedily and certainly perforated. The point thereof must be no bigger then the pin of a Trepan, that so the Trepan which is forthwith to be applied may stand the more firmer, and not play to and again in too wide a hole.

A. Shews the handle. B. The points which may be screwed and fitted into the handle.

CHAP. XVIII. A Description of Trepan.

Trepans are round saws, which cut the bone circularly more or less according to their greatness; they must have a pin standing in the middle a little further out than their teeth, so to stay and hold fast the Trepan that it stir neither to this side nor that, until it be entered and you have cut through the first table at the least: then you must take forth the pin, lest going quite through the bone, it may prick or hurt the *Crassa Meninx*. Wherefore when you have taken forth the pin, you may safely turn it about until you have cut through both the tables; Your Trepan must also have a cap, or somewhat to ingirt or encompass them, lest no way hindred they cut more of the bone than we would, and in conclusion run into the *Meninx*. They must also be anointed with oyl, that so they may cut the more readily and gently; for thus Carpenters use to greafe their saws. But you must, during the time of the operation, often dip them in cold water, lest the bone by attrition become too hot: for all hard solid bodies by quick and often turning about, become hot; but the bone made more hot and dry, is altered and changeth its nature, so that after it is cut, more of it scales and falls away. Now you must know that the bone, which is touched with the Trepan, or the Air, alwayes casts off scales, for the speedier helping forwards whereof, you must strew upon it powders made of Rocket, Briony, wild Cucumber & *Aristolochia* roots. When the bone is sufficiently scaled, let this following powder be put upon it, which hath a faculty to cover the bone with flesh, and and to harden it with dryness convenient to its kind. *R Pulver. Treas Illyricæ, Aloes, Mammæ thuris, Myrrhæ, aristolochiæ an. ʒ j.* Flesh being by this means generated, let it be cicatrized by strewing upon it, the rinds of Pomegranat sand Alum burnt.

The harm the bone receives by being heated with the Trepan. What things hasten the scaling of the bone.

Neither shall the Chirurgeon forcibly take away these scales, but commit that whole work to nature, which useth not to cast them off before that it hath generated flesh under them. For otherwise if he do any thing rashly, he brings new corruption to the bone; as we shall more at large declare, when we come to treat of *Caries* or rottenness of bones.

The bone must not be forcibly scaled.

He which useth the Trepan, must consider this, that the head is of a round figure, and also the Trepan cuts circularly, and therefore it is impossible to cut the bone so equally on every side, as if it were performed upon a plain body. Furthermore the thickness of the skull is not alike in all places, wherefore you must look, and mark whether the Trepan go not more deep on one side than on the other, which you may do by measuring it now and then with a pin or needle, and if yee find that it is cut deeper on one side, than on the other, you must press down the Trepan more powerfully upon the opposite part.

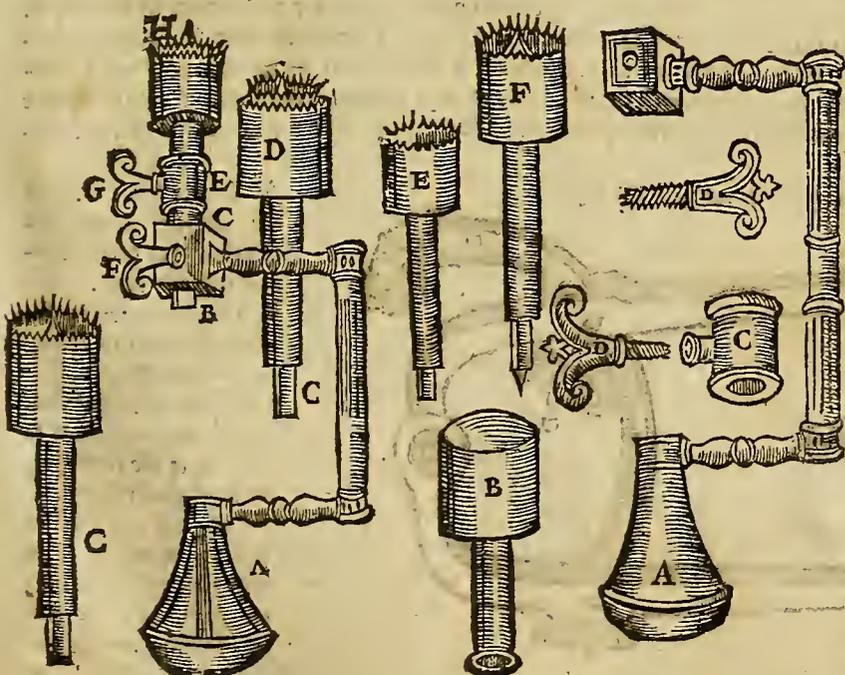

A caution in Trepaning.

But seeing there are many sorts of Trepan invented and expressed by many men, yet if you weigh and rightly consider them all, you shall find none more safe, than that I invented and have here delineated. For it cannot pierce one jot further into the skull, than he pleases that uses it, and therefore it cannot hurt either the *Meninges* or the Brain. An Iron head or cover stayes it as a bar, that it can penetrare no further than you shall think it requisite. This head or cover is to be drawn up and down, and set higher and lower, as he which uses it shall think good, and so it will stay the Trepan that it shall not goe a hairs bredth beyond your intended depth. So that henceforwards there shall be no Chirurgeon, howsoever ignorant in the performance of his Art, which by the benefit of such a Trepan may not perform this operation without any danger or fear of danger of touching the *Dura Mater*, the hurting whereof, puts the life in jeopardy.

A safe and convenient Trepan.

The figure of our Trepan opened and taken in pieces.

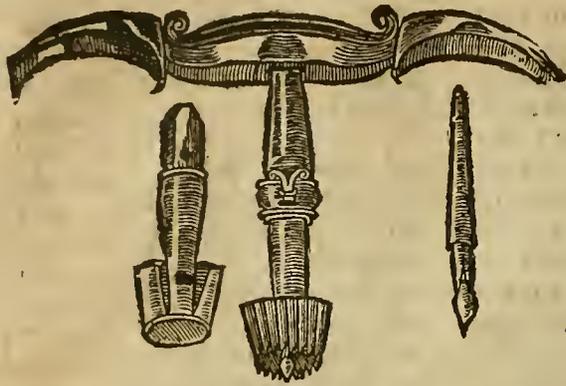

The figure of the same Trepan fitted and put together.

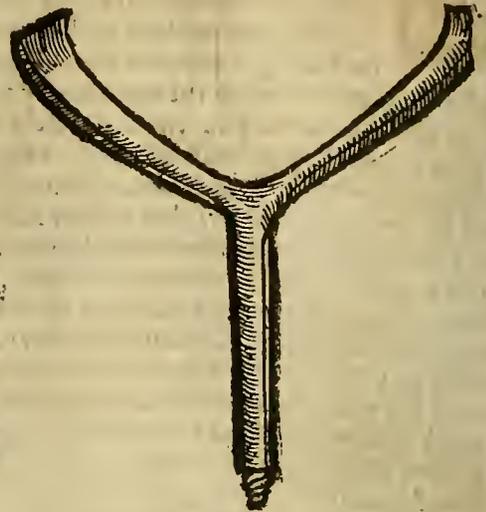

- A. Shews the whole handle or Brace of the Trepan.
- B. The Cover or Cap of the Trepan.
- C. The ferule.
- D. D. The screw pins which hold and stay the ferule and Trepan.
- E. The Trepan without his pin.
- F. The Trepan furnished with its pin.
- A. Shews the Brace and Trepan fitted in every point.
- B. The place into which the Trepan is put, and fitted.
- C. C. C. The upper end of the trepan which is to be fitted and put into the Brain.
- D. The Trepan with its cover or cap up on it.
- E. The ferule.
- F. A screw pin by the twining whereof the Trepan is fastened in the Brace.
- G. Another screw pin which fastens the ferule closer to the Trepan.
- H. The three square points.

In stead of the other Trepan set forth by the Author, I have thought fit to give you the figure of that Trepan that is here most in use, and the fittest therefore, as it is set forth by Mr. Doctor Crook.

A Terebellum or Gimblet consisting of three branches.

A Lentill-like cutting Scraper.

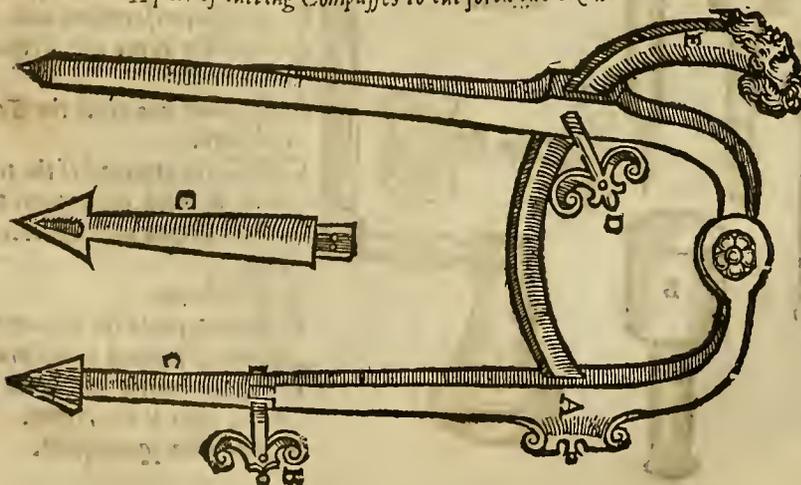

All these particulars of the Trepan taken in sunder, you may see united and fitted together in the other figure. But when you cannot bring out the bone which you have cut off with your Trepan, then you may take it forth with the *Terebellum* or Gimblet here express, that is, screwing the point thereof into the hole made by the three-square pin; the handle of this Instrument may also serve in stead of a Levatory. When with the Gimblet you have drawn or taken forth that part of the skull which was cut away by the Trepan; if there shall be any sharp splinters in the second table, which may hurt and prick the *Meninx*, when it is heaved up by the motion of the brain, they must be shaved away and planed with this Lentill fashioned scraper, being so called, because it hath the head thereof fashioned and smooth like a Lentill, lest being sharpe it should hurt and prick the membrane in the smoothing thereof.

But if by reason of the thickness, the skull cannot be cut with this Lentill-like scraper, you may use the cutting scrapers and a Mallet. The mallet must be of lead, that so it may shake the brain as little as may be. But you must diligently with your mallets take forth the sharp splinters, and peeces of the bone. But if the fractured part of the skull be such, that it will not admit that section which is requisite for the bared bone, as when the fracture is upon the temporall muscle, or at the futures; then in the stead of one Trepan, two or three must be applyed, if the necessity of the present case so require, and that within a very small compass; but they must not be applyed to the fractured part, but nigh thereto, as we shall shew more at large in the following chapter. But the Trepan shall be applyed so neer to each other, that the ring of the second may be joynd with the ring of the first and third. But if a fracture shall happen to light upon a future, then you must not apply a Trepan to it, but use two thereto on each side; he that shall do otherwise, shall tear in sunder the nervous and membranous fibers, and also the veins and arteries by which the *Dura Mater* is fastened to the skull, and yeelds matter to the *Pericranium*. He which shall apply one Trepan, that is, but upon one side of the future, he shall not be able to get forth all the *sanies* which is fallen down on both sides by reason of the partition of the *Crassa Meninx*, which lies between, and rises up by the future of the skull.

To conclude, when for what cause soever we cannot make use of a Trepan, we may imploy this instrument, if so be as much of the bone be bared as is needfull. It is made in form of a pair of Compasses, and by means of a screw may be opened more or less as you please. You as need shall require may change the points, and put other into their places, for they may be fitted to one side of the compass with a screw.

A pair of cutting Compasses to cut forth the skull.

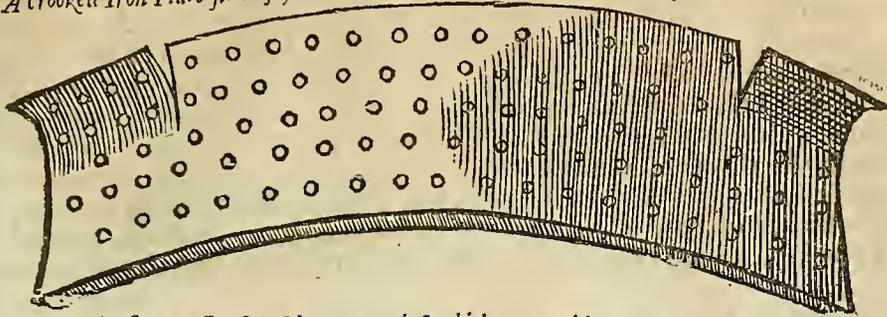

- A. Shews the one leg of the cutting compasses, which as you carry it about cuts the skull.
- B. The screw which fastens the point to the leg of the compasses.
- C. C. Two different points which may be screwed to the leg of the compasses, as need shall require.
- D. A great screw which fastens upon an Iron string, alongst which the one of the legs of the compass running, may be widened & straitned as you please.

More-

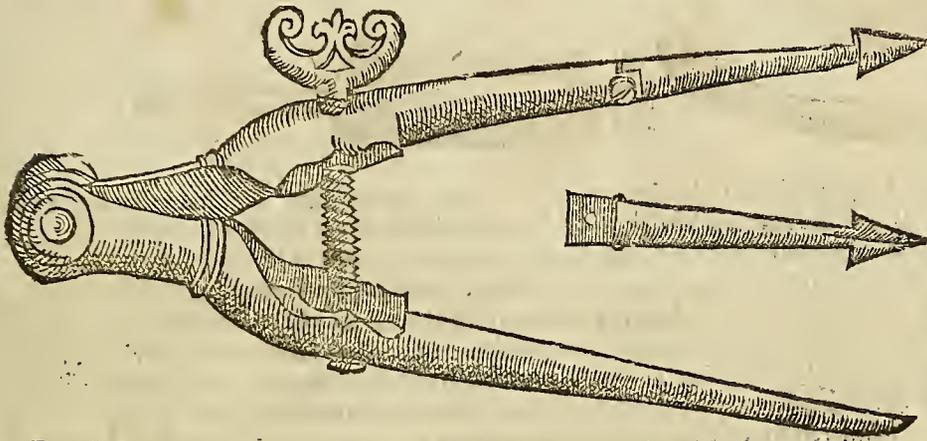

The use of a Leaden Mallet.

Why a Trepan must not be applyed to the futures. Why two Trepanes are to be used to a fractured future.

An crooked Iron Plate fit to sustain and hold steady one leg of the compass upon the head.

Another pair of Compasses of the like nature and use, which may be widened and strained by a screw.

Moreover it is fit that the one leg of such cutting compasses should stand firm and steady, whilst the other is drawn circularly to cut. Wherefore it is fit you have an Iron plate made full of little holes, wherein you may firmly stay that leg of the compass, lest it waver against your will; it is requisite that this plate be crooked, (because the head is round) that so it may be fitted to any part thereof.

CHAP. XIX. *Of the places of the skull whereto you may not apply a Trepan.*

First of all, you shall not apply a Trepan, to a bone that is so broken that it is wholly, or in the greater part thereof divided from the skull by the violence of the stroke, lest by your weight & pressing of the trepan, you force it down upon the membrane. Secondly, you must not apply one to the fractured Sutures, for the reasons mentioned in the former chapter. Thirdly, nor to that part of the forehead which is a little above the eye-browes, for these reasons we gave you before in the twelfth chapter. For there is in that place under the first table of the skull a large cavity replenished with a certain white and tough humor, as also with a certain spirituous and ayrie substance, placed there by nature, to prepare the aire which ascends to the brain by the Nostriils: unlesse the Chirurgion observe and be mindfull hereof, he may be deceived, supposing this cavity to be an Effracture of the bone and a depression thereof. Fourthly, neither in the lowest parts of the skull, lest the marrowy substance of the Brain, by reason of its weight, should slide through the hole made by the Trepan. Fifthly, neither to the *Bregma* bones of Children, as those which as yet have not acquired just solidity, to endure the impression of a Trepan. Sixtly, nor to the temples by reason of the Temporall muscle, the cutting whereof in the opinion of *Hippocrates* causes convulsion of the opposite part. For being cut athwart it loses its proper action, that is, to move and lift up the lower Jaw; but then the opposite Temporall muscle being whole and perfect, using its strength, (his antagonist suffering it, and not resisting or labouring any thing at all to the contrary) it draws the same Jaw to it, whereupon the mouth and all the parts of the face are drawn awry, and suffer a Convulsion towards the sound part, the other being resolved according to *Hippocrates* his rule. For as often as the muscles of one kind are equall in number, magnitude and strength on each side, the resolution of the one part, causes the Convulsion of the other.

A bone almost severed from the skull must not be trepaned.

A notable cavity in the forehead bone.

Lib. de Vul.

A rule out of *Hippocrates*.

What discommodities arise from cutting the temporall muscles.

A History

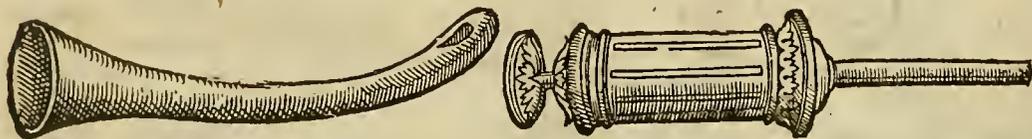

Neither doth this danger alone arise from the cutting of the Temporall muscle, but also another, which is, that this muscle when we eat and speak, is in perpetuall motion, whereby it comes to pass, that being once cut it is scarce ever united again, besides also the commissure or joyning together of the stony bones lye under it. But by the second caution we are forbid to trepan upon the sutures; moreover also many veins, arteries and nerves are spread over the substance thereof, so that by cutting of them, there is danger of many and malign symptomes, as pain, inflammation, a fever, a convulsion not only of the part it self, but also of the whole body, whence lastly death insues. Wherefore let no Chirurgion be so fool hardy, as to attempt the cutting of this muscle so to trepan the bone which lies under it; rather let him apply his Trepan above it, or on the side thereof, or as neer to the affected part as he can, as I did in a Gentleman called *Monsieur dela Bretesche*. He in the triumphant entrance of King *Henry* the second, into the City of *Paris*, was so hurt with a stone, that the *Os Petrosum* or scaly bone, was broken with the violence of the blow, and the temporall muscle was vehemently contused, yet without any wound. I being called the next day (viewing the manner of the hurt, & the condition of the wounded part) thought good to bring some Physitians, and Chirurgions with me to consult hereof, of whom when some thought it expedient presently to divide the temporal muscle that baring the bone we might apply a Trepan, and so take forth the broken bones: I on the contrary, begun earnestly to withstand that opinion, citing that saying of *Hippocrates*, *ex libro de vulneribus Capitis*, wherein Chirurgions are forbidden to cut such muscles, for fear of the forementioned symptomes; also I cited experience, how that I had often observed all those which had this muscle

cut

cut, dyed with a convulsion; but that it should be far better, that neer above the fracture the bone should be trepaned, not touching the Temporall muscle at all if he could. When all of them at the last had inclined to my opinion, I presently divided the musculous skin which was over the upper part of the fracture with a three cornered section: the day following which was the third of his disease, I trepaned him, and after I had done, some few dayes after, I took out some four splinters of the broken bone; and I put in a plain leaden pipe, by which (I wishing the Patient ever when I dreft him to hold down his head, to stop his mouth and his nose, and then strive as much as in him lay to put forth his breath) much sanious matter came forth, which was gathered between the skull and *Crassa Meninx*. Other filth which stuck more fast, I washed out with a detergent decoction, injected with such a syringe as is here exprest; And I did so much, God blessing my indeavours, that at length he recovered.

A plaine leaden pipe for to carry forth the Sanies gathered under the skull.

A little syringe fit to make injections withall.

The like chance and fortune befell *Monsieur de Pienne* at the siege of *Mets*. For he as he fought at the breach of the wall, had the bone of his Temples broken with a stone struck out of the adjacent wall, by a peece of Ordinance shot from the Emperours campe, he presently fel down with the blow, and cast blood out of his mouth, nose and ears, with much vomiting, and remained dumb and as it were senseless almost fourteen dayes, so that he knew none of the by-standers. He had often palpitations; and convulsive twitchings, and his face was swoln. His forehead bone was trepaned at the side of the temporall muscle by the hand of *Peter Aubert* the Kings Chirurgion: and although on the 25. day, soft flesh endued with exquisite sense grew out of the hole made with the Trepan, whose growth could not be hindered by Cathæretick pouders, yet at the length he recovered. The Ancients called this kind of growing flesh a *Fungus* [i. a Mushrome] for that it is soft, and grows with a small root and broad top like a mushrome: but it increases and decreases, according to the plenty of the flowing matter, and industry of the Chirurgion hindering by art the growth thereof. This flesh stinks exceedingly, they commonly call it *Ficus* [anæti *Fiacrii* [i. the fig of *S. Fiacrye*.] This disease commonly hath its original after this manner. Even as in the bodies of trees from the excrements of nourishment, a certain half putrid, gross and viscous humor sweats through the bark, and gathered together by little and little grows into a Mushrom, so blood melancholy both in temper and consistence, springs from the broken vessells of the skull and *Crassa Meninx*, which also is sent sometimes by nature for the necessary repairing of the flesh in these parts, whereupon a certain fungus breeds, which in *Galens* opinion, favors or partakes of the nature & condition of the parts to which it grows though in generall it be of the nature of malign warts, or excrescences. But for to take away such *Fungi*, you must apply medicines which have a specifick faculty to waft superfluous flesh; such are these which strongly dry, and gently waft and eat, such as this which follows. *Rx Sabine ʒ ij. ocreæ ʒj. pulveriscentur simul, aspergatur caro excrescens.* Or else *Rx Hermodactylorum combustorum ʒβ*, make a powder for the same use. But if so be that this fungous flesh come to such growth, (as it often happens) as to equall the bigness of an egg, it must be tied and strait twitched, close to the root with a silken thred; and when it shall fall away by reason of this binding, the place must be strewed with the forementioned pouders, for so it will be more certainly cured, than with more acrid cathæreticks.

CHAP. XX. Of the corruption and Caries, or rottenness of the bones of the Head.

Here sometimes follows a corruption and Sphacell of the fractured bones of the skull upon wounds of the head; which happens either because they are touched by the air, which they are not sensible of; or for that the *Sanies* putrefying and detained under them, hath infected them with like putrefaction; or by the cure unskillfully handled, they by the rash application of suppurating and oily medicines becoming more moist, and so undergoing an unnaturall change of their proper complexion and native temper, as we shall shew more at large, when we shall treat of the reason of the *Caries* in the *Lues venerea*. We shall know this unnaturall change and corruption, partly by sight, that is, when from white they become to be yellowish, livid and black; partly also by putting down a Probe, when as it meets with nothing smooth and slippery, but feels rough in many places, and besides also when it enters and easily penetrates with a small thrusting down into their substance, as if it were fungous. Yet this last sign may often deceive you, for I have divers times observed rotten bones, which being bare had long suffered the injury of the air, to become so hard that a Trepan would scarce pierce them; for it is putrid humidity which makes the bones soft and fungous; but the air by drying them exhausts this humidity, and lastly dries it, whence follows such contumacious hardness. This sign will be far more certain, if the flesh which is grown upon the bone be more soft than is fit, loose and have little or no sense of feeling. You may correct and amend this corruption of the bone with cauteries as well actuall, as potentiall, or with the powders of *Aloes*, *Gentian*, *Aristolochia*, *centaury*, *cortex pini*, as *Rx, radic. Ireos, l'lor. aristo'ochie an. ʒj. centaury. ʒij, corticis pini ʒβ, Misce & fiat pulvis subtilissimus ossi inspergendus.* But if it be much corrupted, it must be scraped forth with your *Scalpra*. And you must expect the falling or scaling of the corrupt bone from the sound, and not forcibly procure it; for otherwise the sound bone, which lies under it, being as yet covered with no flesh growing over it, would be corrupted by the appulse, or touch of the air. Yet you shall by little and little gently move and shake rotten bones with your probe,

A history.

The generation of a Fungus.

Why when the skull is broken the bones sometimes become foul or rotten. The signs of foulness of the bone.

Corrupt bones are sometimes hard.

probe, that so they may more easily scale and with less trouble to nature. But note by the way, that the scaling of the bone which hath invironed the Trepan, is commonly performed in the space of forty or fifty dayes. So long also will that caused by the unusuall appulse or touch of the air, or application of a cautery, or the asperision of the Cephalick powders; besides also in the same number of dayes broken bones may be united and joyned together by a *Callus*, which is to them as a scar, yet sometimes sooner, somewhiles later, according to the variety of the ages, tempers and habits of divers men. But if the *Caries* or *rottenness* can neither by these fore-mentioned remedies be overcome and amended, neither the loosed continuity agglutinated nor united, you must give the Patient a vulnerary potion, for hence I have found happy success in many. But sometimes not only a certain portion of the bone, is taken with a *Caries*, but also the whole is often seized upon with sphacell, and all falls out. For in *Hippocrates* opinion, *Lib. de vulneribus capit. is*, the bone of the skull being broken falls from the sound more or less, according to the violence of the blow; which also is confirmed by experience. For which purpose I think good in this place to recite a History, whereof I was an eye-witness, whilst I served as Chirurgion in *Piemont* under the Marshall *de Montejan* (who was the Kings Lieftenant there.) It happened that a Lackey of *Monsieur de Goulaines* came to me to be cured; he had the *Bregma* bone of the left side broken with a sword, neither yet did the fracture come to the second Table; a few dayes after his recovery the bone being agglutinated and united, it came to pass that a company of *Gascoine* souldiers his countrymen came to *Turin*, with whom one morning he eat plentifully Tripe fryed with Onions and spices, and drunk a great quantity of strong wine. Whereupon he presently fell into a continuall Feaver, and lost his speech and understanding; his head swelled, his eyes looked red and fiery and as though they would have started out of his head. Which things being considered, I let him blood, having first (by the Physitians advice) given him a Glyster, and applyed to his head such things as were fit; and also I laboured with Frictions and Ligatures of the extrem parts to draw the humors downwards; yet for all this the part of the head which was formerly affected began to impostumate; which being opened, there came forth a great quantity of matter, and at the length the musculous skin and *Pericranium* sinking down, both the Tables of the skull became putrefied and rotten, as you might know by their blackness and stench. Now to take away this corruption, I applyed at certain times actuall cauteries, both to amend the corruption and separate that which was altered: but mark, after some months space, a great number of worms came forth by the holes of the rotten bones from underneath the putrefied skull; which moved me to hasten the separation and falling away of the putrid bones. Which being done, upon the very *Crassa Meninx*, which is more strange in that place, which nature had covered with flesh, I observed three cavities of the largeness of ones thumb filled with worms about the bigness of a points tag, with black heads, diversly wrapped amongst themselves. The bone which nature separated was of the bigness of the palm of ones hand, so that it was strange that so large a portion of the skull should be cast off by nature, and yet the Patient not dye thereof; for he recovered yet beyond all mens expectation, but after the agglutination of the wound the scar remained very hollow according to the decree of *Hippocrates*. For flesh doth not easily grow upon a *Callus*, because it is a thing strange and supposititious by nature; besides, as a scar is a thing more dense than the skin, so is a *Callus* than the bone, so that through the more compact substance thereof, the blood can neither freely nor plentifully sweat through for matter to regenerate flesh. Hence it is, that wheresoever any portion of the skull is wanting, you may there by putting to of your hand perceive and feel the beating of the brain, wherefore the skull must needs be much weaker in that place. Now to help this infirmity, I wished this Lacky to were a Cap made of thick leather, so more easily to withstand externall injuries: and verily thereby he grew much better. Now I think good in this place to lay open the deceit and craft of some Impostors falsely stiling themselves Chirurgions, who when they are called to cure wounds of the head, wherein any part of the skull is lost, perswade the Patient and his friends, that they must put a plate of gold in the place of the skull which is wanting. Wherefore they hammer it, in the presence of the Patient, & turne it divers wayes & apply it to the part, the better to fit it; but presently after they slyly convey it into their purses, and so leave the patient thus coufened. Others brag that they are able to put the dried rind of a gourd into the place of the lost bone, and fasten it on to defend the part; and thus they grossely abuse those which are ignorant in the Art. For this is so far from being done that nature will not suffer nor endure so much as an haire, or any other small body to be shut up in a wound when it is cicatrized; neither is the reason alike of a leaden bullet which shot into the body lies there for many years without any harm to the patient; for although lead have a certain familiarity with mans body, yet is it at length (unless the density of the opposed flesh, ligament, tendon, or some other such like substance hinder) thrust forth by nature impatient of all strange bodies. And thus much of the rottenness and corruption of fractured bones; now must we speak of the discommodities which befall the *Meninges* by wounds whereby the skull is broken.

sters.

CHAP. XXI. Of the discommodities which happen to the *Crassa Meninx* by fractures of the skull.

Any discommodities chiefly happen to the *Crassa meninx* by a fracture of the skull and rash trepaning thereof; for it sometimes chanches to be cut and torn. Agglutination is a remedy for this disease, which *Hippocrates* wishes to be procured with the juice of *Nepeta* [that is, of that calamint, which smells like Penny-royall] mixed with barley flour. In stead whereof this following powder having the like faculty may take place.

R. Colophon. ℥iij. Myrrha, aloes, mastiches, sanguinis Dracon. an. ʒi. croci, sarcocollæ an. ʒβ. misce & fiat pulvis subtilis. But to purge the blood and matter which is gathered and lyes between the *Crassa meninx* and skull, you shall put in a Tent made of a rag twined up some foure or five double, and steeped in sy-

Remedies
for the la-
cerated
Meninges
rup

rup of Roses or wormwood and a little *Aqua vite*; for thus you shall press down both the *Crassa Meninx*, left lifted up by the accustomed and native pulsation of the brain; it should be hurt by the edges of the skull, yet rough by reason of the sharp splinters of the bone lately trepaned, and give freer passage forth for the matter there contained. But as oft as you shall dress the Patient, you shall renew the forementioned Tent, until all the matter be purged forth. And so often also you shall press down with the following instrument the *Dura Mater*, and bid the Patient to strive to put forth his breath, stopping his mouth and nose, that so the matter may more easily be evacuated. This Instrument wherewith you shall hold down the *Dura Mater*, must have the end round, polished and smooth as it is here express'd.

A fit Instrument to press and hold down the Dura Mater, so to make way for the passage forth of the Sanies or Matter.

And let there be laid upon the *Dura Mater* strewed over with the fornerly mentioned powder, a sponge moistened and wrung forth of a drying decoction made of aromatick and cephalick things, such as this which follows. *Rx Fol. salviae, majoran. betonicae, rosar. rub. absinth. Myrtil. forum chamen. melil. stoebad. utriusque an. M. iij. rad. cyperi, calam. aromat. ireos, caryophyllatae, angelicae, an. ʒij. bulliant omnia secundum artem cum aqua fabrorum & vino rubro, fiat decoctio ad usum dictum.* And in stead hereof you may use claret with a little *aqua vite*, that so the contained matter may be evacuated and dried up. A sponge is fitter for this purpose to draw than a linnen rag or any other thing, both because it is good of it self to draw forth the humidity, as also for that by its softness it yields to the pulsation of the Brain. Then apply to the wound & all the adjoining parts, an emplaster of *Diacaltheos* dissolved with vinegar, or wine, or oyl of Roses, that so the plaster may be the more cold and soft. For in *Hippocrates* opinion, nothing which is any thing heavy or hard must be applied to wounds of the head, neither must it be bound with too strait, or hard a ligature, for fear of pain and inflammation.

For *Galen* tells (as he had it from *Mantias*) that a certain man had lost his eyes by inflammation and impostumation arising, for that an Apothecary had used too strait a ligature to his head and face; for this strait ligature so pressed the futures, that the fuliginous vapours, which used to pass through them and the pores of the skull, were stopped from passing that way; besides, the beating of the Arteries was intercepted and hindered; by which means the pain and inflammation so increased, that his eyes were rent and broke in sunder and fell forth of their orb. Wherefore *Hippocrates* rightly commends an indifferent ligature: also he sicly witheth us to let the emplasters be soft which are applied to the head, as also the cloaths wherewith it is bound up, to be of soft and thin linnen, or of Cotton, or wooll. When the patient is in dressing, if there come much matter out of the wound, you shall wish him if he can, to lye upon the wound, and now and then by fits to strive to breath, stopping his mouth and nose, that so the brain lifted and swoln upwards, the matter may be the more readily cast forth; otherwise suffer him to lye so in his bed, as he shall best like of, & shall be least troublesome to him. You may with good success put upon the *Crassa Meninx* oyl of Turpentine with a small quantity of *aqua vite* and a little Aloes and Saffron finely powdred, to cleanse or draw forth the *Sanies*, or matter. Or else, *Rx Mellis rosar. ʒij. farinae hord. pulver. aloes, mastich. & Ireos florent. an. ʒij. aqua vite parum;* let them be incorporated together & make a detensive medicine for the foresaid use.

Sometimes also the *Crassa Meninx* is inflamed after Trepaning, and swoln by a *Phlegmon*, that impatient of its place, it rises out of the hole made by the Trepan, and lifts it self much higher then the skull, whence grievous symptoms follow. Wherefore to prevent death, of which then we ought to be afraid, we must enlarge the former hole with our cutting mallets, that the matter contained under the skull, by reason of whose quantity the membrane swells, may the more freely breath and pass forth; and then we must goe about by the prescript of the Physitian to let him bleed again, to purge and diet him. The inflammation shall be resisted by the application of contrary remedies, as this following fomentation. *Rx Sem. lini, althaeae, fan. psyllii, rosar. an. ʒj. solani, plantag. an. M. j. bulliant in aqua tepida communi, ex qua fiat solus.* Anodyne and repelling medicines shall be dropped into his eares, when it is exceedingly swoln, that the tumor may subside, you shall cast upon it the meal or floure of lentills, or vine leaves beaten with Goose greafe. With all which remedies if the tumor doe not vanish, and withall you conjecture that there is Pus or matter contained therein, then you must open the

Dura Mater with your incision knife, holding the point upwards & outwards, for so the matter will be poured forth and the substance of the brain not hurt nor touched. Many other Chirurgions, and I my self have done this in many patients with various success. For it is better in desperate causes to try a doubtfull remedy then none at all; also it oft-times happens, whether by the violence of the contusion and blow, or concretion or clotting of the blood which is shed, or the appulse of the cold ayre, or the rash application of medicines agreeing neither in temper nor complexion with the *Crassa Meninx*, or also by the putrefaction of the proper substance, that the *Dura Mater* it self becomes black. Of which synptome the Chirurgion must have a great and special care.

Therefore that thou mayst take away the blackness, caused by the vehemency of the contusion, you shall put upon it oyl of egges with a little *Aqua vite*, and a small quantity of Saffron and Orris roots in fine powder; you shall also make a fomentation of discussing and aromatick things boyled in water and wine; and *Vigoes Cerat* formerly described shall be applycd. But if the harm come from congealed blood, you shall withstand it with this following remedie. *Rx Aqua vite ʒij. granor. tinctorum in tenuem pulverem tritorum ʒij. croci, ʒi. Mellis rosar. ʒij. Jarcoool. ʒij. Leviter & simul bulliant omnia, & de colatura infundatur, quousque nigrities fuerit oblitterata.* If this affect come by the touch of the ayre, it shall be helped with this following remedie. *Rx Tereb. ven. ʒij. Mellis ros. ʒij. Vitellum ovi u-*

nam *farin. borderi* ℥ij. *croci* ℥j. *sarcocol.* ʒij. *aq. vitæ* ʒij. Incorporentur simul, & bulliant paululum. This remedy shall be used until the blackness be taken away, and the membrane recover its pristine colour.

But if this affect proceeds from the rash use of medicines, it must be helped by application of things contrary. For thus the offence caused by the too long use of moist and oily medicines, may be amended by using catagmatick and cephalick powders; but the heat and biting of acrid medicines, shall be mitigated by the contrary use of gentle things; for both humid and acrid things somewhat long used make the part look black, that truly by generating and heaping up filth, but this by the burning and hardening heat. But when such blackness proceeds from putrefaction, *Iohr de Vigo* commends the following remedy. *R aqua vitæ* ʒij. *mellis ros.* ʒij. But if the affect be grown so contumacious that it will not yeeld to this gentler remedy, then this following will be convenient. *R Aqua vitæ* ʒij. *mellis ros.* ʒij. *putver. Mercur.* ʒij. *unica ebullitione bulliant simul ad ujam dictum.* Or *R aqua vit.* ʒij. *lyrup. absinth.* & *mellis ros. at. an.* ʒij. *unguenti egyptiaci* ʒ. *ʒ. sarcocol. myrrhæ, aloes. an.* ʒj. *vini albi boni & odoriferi.* ʒj. *bulliant leuiter omnia simul, coeantur ad ujam dictum.* But if the force of the putrefaction be so stubborn, that it will not yeeld to these remedies, it will be helped with *Aegyptiacum* (made with plantain water in stead of Vinegar) used alone by it self, or with the powder of Mercury alone by it self, or mixt with the powder of Alome. Neither must we be afraid to use such remedies especially in this extreame disease of the *Dura Mater*; for in *Galens* opinion the *Crassa Meninx* after the skull is trepaned delights in medicines that are acrid, that is, strong and very drying, especially if it have no *Plegmon*; and, this for two reasons; the first is, for that hard and dry bodies, such as membranous bodies are, be not easily affected unless by strong medicines; the other is, which must be the chiefe and prime care of the Physitian, to preserve and restore the native temper of the part by things of like temper to it. But if the auditory passage not onely reaching to the hard membranes of the Brain, but also touching the Nerve which descends into it from the brain, suffer most vehement medicines, though it be placed so near; certainly the *Crassa Meninx* will endure them far more easily and without harm. But if by these means the putrefaction be not restrained, and the tumor be increased so much, that the *Dura Mater* rising far above the skull, remains unmovable, black and dry, and the patients eyes look fiery, stand forth of his head and rowl up and down with unquietness and a phrensie, and these so many ill accidents be not fugitive, but constant, then know that death is at hand, both by reason of the corruption of the gangran of a noble part, as also by extinction of the native heat.

For the hurt received by the ayre.

What Medicins make the *Crassa Meninx* black.

Medicins that putrefact on of the *Meninx*.

VVhy the *Crassa Meninx* easily endures acrid medicins.

Signs of death at hand.

CHAP. XXII. Of the cure of the Brain being shaken, or moved.

WHE formerly declared the causes, signes and symptoms of the concussion, or shaking of the Brain, without any wound of the muscular skin, or fracture of the bone; wherefore for the present I will treat of the cure. Therefore in this case, for that there is fear that some vessell is broken under the skull, it is fit presently to open the cephalick vein. And let blood be plentifully taken according to the strength of the Patient, as also respectively to the disease both which is present, and like to ensue, taking the advice of a Physitian. Then when you have shaven away the haire, you shall apply to the whole head and often renewe the forementioned cataplasme, *Ex farinis, oleo rojacco, oxymelite,* and other like cold and moist repelling medicines. But you must echeew dry, and too astringent medicines must be shunned, such as are *Unguentum de bolo* and the like; for they obstruct too vehemently, and hinder the passage forth of the vapours both by the sutures and the hidden pores of the skull. Wherefore they doe not only not hinder the inflammation, but fetch it when it is absent, or encrease it, when present. The belly shall be loosed with a clyster, and the acrid vapours drawne from the head; for which purpose also it will be good, to make frictions from above downwards, to make straight ligatures on the extreame parts, to fasten large cupping-glasses with such flame to the shoulders and the originall of the spinall marrow, that so the reuulsion of the blood running violently upwards to the brain, and ready to cause a plegmon, may be the greater. The following day it will be convenient to open the *Vena Puppis*, which is seated upon the Lambdall suture, by reason of the community it hath with the veins of the brain, & shutting the mouth and nose to drive powerfully to breath. For thus the membranes swell up, and the blood gathered between them and the skull is thrust forth; but not that which is shut up in the brain and membranes, of which if there be any great quantity, the case is almost desperate, unless nature assisted with stronger force, cast it forth turned into Pus. But also after a few dayes the *vena frontis* or forehead vein may be opened, as also the Temporall Arteries and Veins under the tongue, that the conjunct matter may be drawn forth by so many open passages. In the mean space the Patient must keep a spare diet, and abstain from wine, especially until the fourteenth day, for that until that time the fearfull symptoms commonly reign. But repelling medicines must be used until the fourteenth day be past, then we must come to discussing medicines, beginning with the more milde, such as is this following decoction. *R rad. Alib.* ʒvj. *ireos, cyperi, calami arom. an.* ʒij. *fol. sabinis, sngior an. betonic. stor. chamem. melil. ros. rub. stachad. an.* M. ʒ. *alis com.* ʒij. *bulliant omnia simul secundum artem cum vino rub. & aqua savorum, fiat decoctio.* Let the head be washed therewith twice a day with a sponge. But yet when you do this, see that the head be not too much heated by such a fomentation, or any such like thing, for fear of pain and inflammation. Then you shall apply the cerate of *Vigo* which hath power to discuss indifferently, to dry, and draw forth the humors which are under the skull, and by its aromatick force and power to confirm and strengthen the brain; it is thus described. *R Furfuris bene triturate* ʒij. *farin. lentini* ʒij. *ros. myrtillor. foliorum & granorum ejus, an.* ʒj. *calam. aromati.* ʒj. *ʒ. chamem. mel. melil. M.* ʒ. *nucis cupressi num. vj. olei rojacei, & chamem. an.* ʒij. *ceræ albæ* ʒij. *ʒ. thuris, mastichis, an.* ʒij. *myrrhæ* ʒij. *In pulverem que redigi debent radactis, & liquefactis oleis cum cera, omnia misceantur simul, & fiat mixtura, que erit inter formam emplastris & cerati.*

What the concussion of the brain is.

The opening of the *Vena Puppis*.

A discussing fomentation.

A caution in fomenting the head.

A description of *Vigoes* Cerate.

A History. *Vigo* saith, that one of the Duke of *Urbins* Gentlemen found the urine hereof to his great good. He fell from his horse with his head downwards upon hard Marble, he lay as if he had been dead, the blood gush't out of his nose, mouth and ears, and all his face was swollen and of a livid colour; he remained dumb twenty dayes, taking no meat but dissolved gellies, and Chicken and Capon broths with sugar; yet he recovered, but lost his memory, and faltered in his speech all his life after. To which purpose is that Aphorism in *Hippocrates*; Those which have their Brain shaken by what cause soever, must of necessity become dumb; yea also, as *Galen* observes in his Commentary, lose both their sense and motion. That Cerat is not of small efficacy, but of marvellous and admirable force, which could hinder the generating of an abscess, which was incident to the brain by reason of the fall. Yet there be many men so far from yeelding to reason, that they stily deny, that any impostumation can be in the brain; and augmenting this error with another, they deny that any who have a portion of the brain cut off can recover, or rise again; but the authority of ancient writers and experience do abundantly refell the vanity of the reasons whereon they rely. Now for the first, in the opinion of *Hippocrates*; If those which have great pain in their heads have either pus, water or blood flowing from their Nose, mouth or ears, it helps their disease.

Aph. 58. sect. 7.
That there may be an abscess in the brain.
Aph. 10. sect. 6.

Gal. lib. de inaequal. in temp. Rbas. cap. 4. contin. Avicen. cap. de exil. sen. 3. lib. 4. cap. 20.
A History. But *Galen*, *Rhasis*, and *Avicen* affirm that Sanies generated in the brain disburdens it self by the nose, mouth or ears; and I my self have observed many who had the like happen to them.

I was told by *Prothais Coulen*, Chirurgeon to *Monsieur de Langey*, that he saw a certain young man in the town of *Mans*, who often used to ring a great bell; he once hanging in sport upon the rope; was snatcht up therewith and fell with his head full upon the pavement: he lay mute, was deprived of his senses and understanding, & was besides hard bound in his belly. Wherefore presently a fever and delirium with other horrid symptoms assayled him, for he was not trepaned because there appeared no sign of fracture in the skull: on the seventh day he fell into a great sweat with often sneezing, by violence whereof a great quantity of matter and Pus flowed forth of his ears, mouth and nose, then he was eased of all his symptoms, and recovered his health.

Lib. 8. de usu part. & com. ad aph. 18. sect. 6. Now for the second, *Galen* affirms that he saw a boy in *Smyrna* of *Ionia* that recovered of a great wound of the brain, but such an one as did not penetrate to any of the ventricles. But *Guido* of *Cauliac* saith, he saw one which lived and recovered after a great portion of the brain fell out by reason of a wound received on the hind part of his head. In the year of our Lord 1538. while I was Chirurgeon to the Marshall of *Montejan* at *Turin*, I had one of his Pages in cure, who playing at quoits received a wound with a stone upon the right *Bregma* with a fracture, and so great an Effraction of the bone, that the quantity of half a hazell Nut of the brain came forth thereat. Which I observing, presently pronounced the wound to be deadly; a Physitian which was present contradicted my opinion, affirming that substance was no portion of the brain, but a certain fatty body. But I with reason and experience in presence of a great company of Gentlemen, convinced the pertinacy of the Man, with reason; for that fat cannot be generated under the skull, for although the parts there contained be cold, yet because they are heated by the abundance of the most hot and subtile animall spirits, and the heat of vapours rising thither from all the body, they do not suffer fat to concreat about them. But with experience, for that in the dissecting of dead bodies, there was never any fat observed there; besides also fat will swim on the top of water; but this substance as marrowy, cast into the water presently sunk to the bottome.

Why fat cannot be generated under the skull. Signs of a fatty substance. Lastly, fat put to the fire becomes liquid and melts; but this substance being laid upon a hot iron, became dry, shrunk up and contracted it self like a peece of leather; but dissolved not at all. Wherefore all those which were present cryed out, that my judgment was right of that substance that came forth of the skull. Yet though it was cut away, the Page recovered perfectly, but that he continued deaf all his life after.

CHAP. XXIII. Of the wounds of the face.

Why we treat in particular of wounds of the face.

Having treated of the wounds of the head by their causes, signs and cure, it follows that we now speak of the wounds of the face, if but for this, that when they are carelessly handled, they leave deformed scars in the most specious and beautifull part of the body. The causes are the same which are incident to the skull, that is, external. But this may be added to the kinds and differences of the wounds, that the life may be out of danger though any one whole part of the face, (as the ear, eye, nose, lip) may be cut away by a wound, but not so in the head or skull. Wherefore beginning at the wounds of the eye-brows, we will prosecute in order the wounds of the other parts of the face.

A thing to be observed in wounds of the eye-brows.

This is chiefly to be observed in wounds of the eye-brows, that they are oft-times cut so overthwart, that the muscles, and fleshy pannicle which move and lift them up, are wholly rent and torn. In which case the eye-lids cannot be opened, and the eyes remain covered, and as it were shut up in the cases of their lids; so that even after the agglutination of the wound, if the Patient would look upon any thing, he is forc'd to hold up the eye-lids with his hand; with which infirmity I have seen many troubled, yet oft-times not so much by the violence of the wound, as by the unskilfulness of the Chirurgeon who cured them; that is, by the negligent application of the boulders, an unfit ligature and more unfit suture. In this case the skilfull Chirurgeon which is called to the Patient shall cut off as much of the skin and fleshy pannicle as shall serve the eye-lids, that so they may by their own strength hold and keep open, without the help of the hand: then he shall sow the wound as is fit, with such a stitch as the Furriers, and Glovers use; and then he shall pour thereon some of the balsome of my description, and shall lay such a medicine to the neighbouring parts. *Rx Olei ros.*

far. \mathfrak{z} β , album. ovor. nu. ij. boli armeni, sanguinis Dracon. Mastich. an. \mathfrak{z} j. agitentur simul, fiat medicamentum. Then let the part be bound with a fitting Ligature. Afterwards you shall use Emplast. de gratia Dei, Empl. de Betonica, Diacalctheos, or some other like, untill the wound be cicatrized. But such like and all other wounds of the face may be easily healed, unless they either be associated with some malign symptoms, or the Patients body be repleat with ill humors.

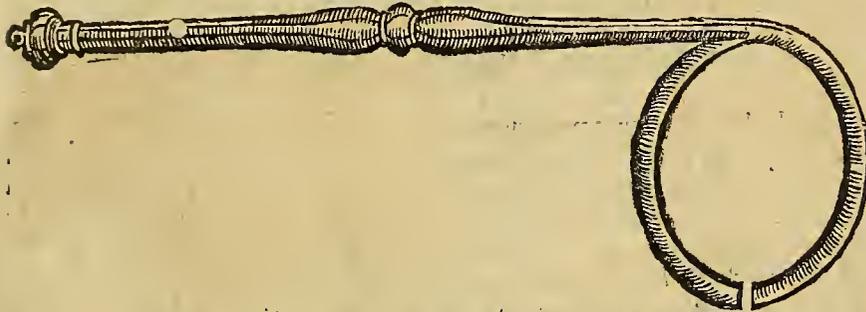

There sometimes happens a quite contrary accident in wounds of the eye-brows, that is, when the eye-lids stand so up that the Patient is forc'd to sleep with eyes open, wherefore those which are so affected are called by the Greeks *Lagophthalmi*. The cause of this affect is often internall, as a carbuncle or other kind of abscess, as a blow or stroak. It shall be cured by a crooked or semicircular incision made above the eye-lids, but so that the extreame of the semicircle bend downwards, that they may be pressed down and joyued as much as is needfull to amend the stiffness of the eye-lid. But you must not violate the gristle with your Instrument, for so they could no more be lifted up; the residue of the cure must be performed as is fit.

Lagophthalmia is a quite contrary to the falling down of the eye-lids;

CHAP. XXIII. Of the wounds of the eyes.

Wounds of the eyes are made by the violence of things pricking, cutting, bruising, or otherwise loosing the continuity. But the cure must alwayes be varied according to the variety of the causes and differences. The first head of the cure is, that if any strange and heterogeneous body shall be fallen into the eyes, let it be taken forth as soon as you can, lifting and turning up the eyelid with the end of a spatula. But if you cannot discern this moat or little body, then put three or four seeds of Clary, or *Oculus Christi* into the pained eye. For these seeds are thought to have a faculty to cleanse the eyes and take out the moats, which are not fastened deep in, nor do too stubbornly adhere to the membranes. For in this case, you shall use this following instrument, for herewith we open the eye-lids the further, putting it between them and the eye, and also keeping the eye steady by gently pressing it, that so with our mallets we may pull out the extraneous body; this is the figure of such an Instrument.

The delineation of a *Speculum oculi*, fit to dilate and hold asunder the eye-lids, and keep the eye steady, it is so made, that it may be dilated and contracted according to the greatness of the eyes.

All strange bodies taken out, let this medicine be put into the eye. Take the strains of a dozen eggs, let them be beaten in a leaden Mortar, with a little Rose water, and so put into the eye; but let this repercussive be laid upon the eye and the

A repercussive to be put into the eye.

neighbouring parts. *Rx.* album. ovor. nu. iij. pulver. aluminis roche combusti \mathfrak{z} ij. sanguinis Draconis \mathfrak{z} j. aqua rosar. & plantag. an. \mathfrak{z} ij. agitentur simul, make a repercussive, which you may frequently use. Or else apply cheefe curds well wrung, mixed with rosewater, the white of an egge, and as much acacia as shall suffice. This which followeth doth more powerfully stay the flowing humor. *Rx.* gum arab. & tragac. an. \mathfrak{z} ij. psyllii. cydon. semin. portul. plant. sumach. an. \mathfrak{z} ij. fiat mucag. cum aqua plantag. solan. & rosar. concinetur collyrium, of which you may drop some both within and about the eye.

Divers repercussives to be applied to the eye.

But note, that all such remedies must be applyed warm, both that they may the better penetrate by their moderate heat, as also for that all actuall cold things are hurtfull to the eyes and sight, because they dull the sight by incrustating the visive spirits. For I have known many who have become dull of sight by the frequent using of medicines actually cold to the eyes. I have on the contrary seen not a few, who have recovered with the fit use of such like medicines, who have had any part of their eye (so it were not the *pupilla* or apple of the eye) so pricked with a needle or bodkin; that much of the waterish humor ran forth thereat.

Things actually cold are hurtfull to the eyes.

The milk of a woman which suckles a girl (for that is reputed the cooler) mitigates pain and clenches, if it be milked out of the Dug into the eye; to which purpose also the blood of Turtles, Pigeons or Chickens much conduces; being dropt into the eye by opening a vein under their wings. Also this following cataplasm asswageth pain and inflammation, and hinders defluxion, being applyed to the eye and the adjacent parts. *Rx.* Carnis pomorum sub cinere calido decoctorum \mathfrak{z} v. vitellos ovorum num. iij. casia fistula recent er extracte \mathfrak{z} β , mucaginis psyllii, althea & cydon. an. \mathfrak{z} j. farin. hordei parum, incorporentur omnia simul, fiat cataplasma. Also sheeps lungs boyled in milk and applyed warm, and changed as they grow cold, are good to asswage pain. But if the too violent heat and pain, shall not yeeld to such medicines, but require more vehement, then *Foliorum Hyoscyami*, m. j. sub. cineribus coquatur, atque in mortario cum mucagine seminis psyllii, & cydonior. extract. in aquis solani & plantag. pistetur: then let this medicine be wrapped in a linnen cloth and applyed to the eyes and temples. The mucilages of *Psyllium*, or Fleawort, and Quince seeds extracted in a decoction of Poppy heads and mixed with a little Opium and Rose water, are used for the same purpose. But when there is need of detergent and sarcotick medicines, then *Rx.* Syrup. rosar. seccar. \mathfrak{z} j. aq. sanic. & ruta an. \mathfrak{z} ij. aloes lotæ, olibani an. \mathfrak{z} β . mix them for the foresaid use. The galls of Scates, Hares, and Partridges dissolved in Eye-bright, and Fennill water, are fit for cleansing such wounds; as also this following Collyrium. *Rx.* Aqua hordei \mathfrak{z} j. mellis despumati, \mathfrak{z} iij. aloes ter lotæ in aqua plantaginis & sacchari cand. an. \mathfrak{z} j, fiat collyrium. Also this insuing medicine is very sarcotick. *Rx.* mucagin. gummi olibani, arabici, tragacanth. & sarcocol. in aq. hordei extract. an. \mathfrak{z} iij.

Anodyne medicines for the eyes.

Narcotick ticks.

Detergent medicines.

A sarcotick medicine for the eyes.

aloes ter lota in aq. rosarum. ʒj. cerus. uste & lota, tutia prepar. an. ʒβ. fiat collyrium. But here you must note, that the coat *Adnata* often swells so much by reason of a wound or some other injury, and stands so forth by the falling down of humors, access and mixture of flatulencies, that it hides the whole *Pupilla*, and hangs forth of the eye-lids, like as if it were an unnaturall fleshy excrescence, and it looses the native colour, and looks very red, so that the eye can neither be shut nor opened.

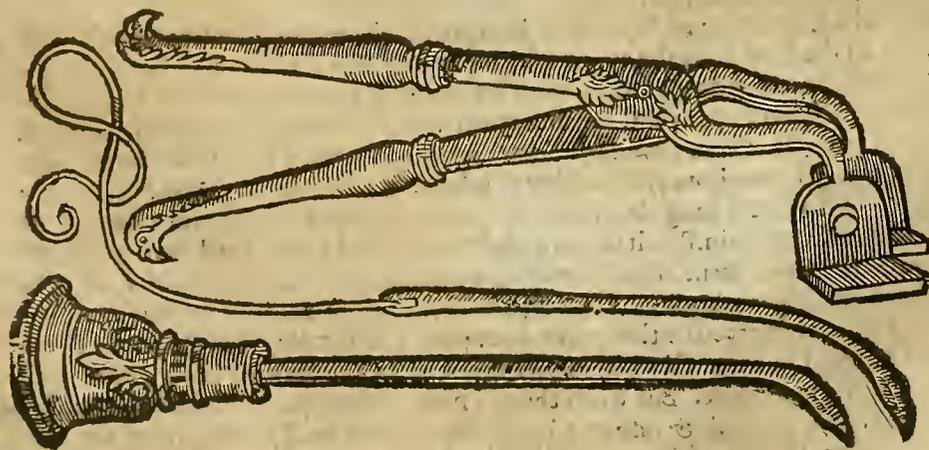

Where with a young Chirurgeon being deceived, determined to cut away this protuberancy of the *Adnata*, as though it had been some superfluous flesh, and then to wash it with cathæretick powders, had I not forbidden him, telling him of the certain danger of blindness which would thereupon befall the Patient. Wherefore I prescribed a fomentation of chamomile, melilote, Rose leaves, wormwood, rue, fennill, and aniseeds boyled in milk with the roots of Orris and Marigolds. Then I presently added this following fomentation, being more powerfull and drying. *R Nucis cupressi, gallar. balauft. an. ʒj. plantag. absinth. hippuris, flo. chamem. ros. rub. an. M.β. bulliant simul cum aqua fabrorum, & fiat decoctum: pro fotu cum spongia.* Besides also you may apply a cataplasm made of barley and bean flowre, the powders of Mastick, Myrrhe, and Aloes, and some of the last described decoction. The tumor beginning to decline, I dropt the flowing liquor into the eye, which hath a very astringent, drying and strengthening faculty. Roast a new laid egge in Embers untill it be hard, then pill off the shel, take forth the yolk, and in place thereof put a scruple of Roman Vitrioll in fine powder, then put it in a linnen cloth and wring it hard forth into some clean thing, and drop thereof for some dayes into the eye, with a little Smiths water wherein Sumach and Rose leaves have been boyled. I have found by experience the certain force of this remedy; but if notwithstanding there be a true fleshy excrescence upon the coat *Adnata*, it may be taken away by this following powder. *R Ossis sepiæ, & teste ovorum calcinata an ʒj. fiat pulvis.* Calcined Vitriol, burnt Alum and the like may be commodiously used to this purpose. Yet you must warily make use of all such things, and always lay repercussives about the eye, that no harm insue thereof. For divers times acrid humors fall down into the eye with such violence, that they break the Horny coat, whereupon the humors of the eye are poured out. Remember also, that in diseases of the eyes, the Patient lye with his head somewhat high, and that he keep shut not only the pained, but also the sound eye, because rest is always necessary for the grieved part. But one eye cannot be moved without some motion of the other by reason of the connexion they have by their optick and moving nerves, both the *Meninges* and the *Pericranium*, Veins and arteries; which is the cause that when the one suffers, the other in some sort partakes therewith.

But if we cannot prevail by all these formerly prescribed medicines fit to stay the defluxion, then it remains, that we apply a Seton to the neck; for it is a singular remedy against inveterate defluxions into the eyes. For we know by dayly experience, that many who have had their sight dulled by a long and great defluxion, so that they were almost blind, have by little and little recovered their former splendour and sharpness of sight, when matter once begun to be evacuated by the Seton.

The truth hereof appeared in *Paul the Italian Goldsmith*, who dwelt neer the Austine Friers. For he having used many medicines of divers Physitians, and Chirurgeons in vain, when he was almost blind, he applying a Seton, by mine advice, began by little and little to see better according to the quantity of the matter which was evacuated, untill at length he perfectly recovered his sight. But at last growing weary of the Seton which he had worn for a year (although matter came dayly forth thereof) yet he would have it taken forth, and healed up; but this way of evacuation being shut up, and the humor again beginning to flow into his eyes, so that he was in danger to become blind, he called me and made me again to apply the Seton in his neck. Whereby recovering his former soundness and perfection of sight, he yet wears the Seton.

I also once freed by this kind of remedy, by the appointment of the most learned Physitian *Hollerius*, a certain young man of twenty years old, from the falling sickness, who before had many fits thereof; the Ichorous humors, the feeders of this disease, being by this means, as it is most probable, drawn away and evacuated.

A figure of the Pincers, a true Cautery and Needle used in making a Seton.

Wherefore seeing a Seton is of this use, I have thought good in this place to set down in writing, and by figure, the manner of making thereof, for the behoof of young practitioners: with the Patient to sit on a low stool, and to bend down his head, that so the skin and fleshy pannicle may be relaxed; then must you with your fingers

pluck up and sever the skin from the muscles, and take hold of as much hereof as you can with your pincers, not touching the muscles of the neck for fear of a convulsion and other symptoms; you shall then twitch the skin which is held in the pincers, most hard, when you shall thrust the hot Iron through

A drying fomentation.

A medicine to consume a fleshy excrescence without biting.

A Seton, a good remedy against inveterate defluxions into the eyes.
A History.

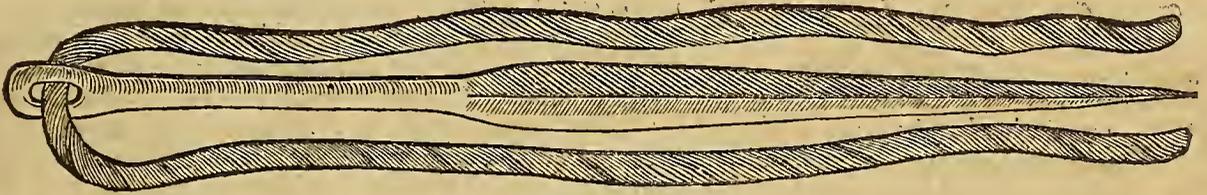

A Seton good against the falling sickness.

The manner of making a Seton.

through the holes made in the midst of them; that also the nerves being so twitched, the dolorifick sense may the less come to the part. The wound must be made or burnt in long wayes, and not thwarting, that so the matters may be the better evacuated by the strait fibers. But the cautery or hot Iron must have a three or else a four-square point & that sharp, that so it may the more easily and speedily enter. Then keeping the pincers immoveable, let him draw through the passage made by the cautery a needle thred with a three or four doubled thred of Cotton [or rather a skean of silk] moistened in the white of an egge and oyl of Roses; then after you have applyed pledgets dipped in the same medicine, bind up the part with a convenient ligature. The day following the neck must be anointed with oyl of Roses, and the pledgets dipped in the former medicine applyed for some dayes after. But it will be convenient to moisten the Seton with a digestive made of the yolk of an Egge and oyl of Roses, untill the ulcer cast forth much matter; then you shall anoint the Cotton thred with this following remedy. \mathcal{R} *terebinthina ven.* \mathfrak{z} *iiij.* *syrupi rosar.* & *absinthii an.* \mathfrak{z} β *pulveris Iros, diacrydii, agarici trochiscati, & Rhei, an.* \mathfrak{z} β . *incorporentur omnia simul & fiat medicamentum.* Which you shall use so long, as you intend to keep open the ulcer. For it hath a faculty to draw the humors from the face, and cleanse without biting.

I have found not long since by experience, that the apertion made with a long thick Triangular needle of a good length like to a large pack-needle, is less painfull than that which is performed with the actuall cautery, which I formerly mentioned. Wherefore I would advice the young Chirurgion, that he no more use the foresaid actuall cautery. I have here given you the figure of the needle.

The Figure of a Triangular Needle.

CHAP. XXV. Of Wounds of the Cheek.

Seeing a wound of the cheek seems to require a suture, it must have a dry suture (as they term it) lest that the scar should become deformed. For that deformity is very grievous to many, as to women who are highly pleased with their beauties. Therefore you shall spread two peeces of new cloth of an indifferent fineness, and proportionable bigness with this insuing medicine. \mathcal{R} : *pulveris mastichini, sanguinis Draconis, iburis, farinae volatilis, tragacanthæ contusa, gypsi, picis, sarcocollæ an.* \mathfrak{z} *ij.* *picis nigrae* \mathfrak{z} *i* β . *albumina ovorum quæ sufficiant, fiat medicamentum.* Apply the peeces of cloth spread with this on each side of the wound one, some fingers breadth asunder, and let it alone till it be hard dried to the skin. Then you shall so draw them together with your needle and thred, that the flesh by their sticking may also follow, and be mutually adjoined, as you may see it here exprest. The wound shall be agglutinated by this means, together with the use of fit medicines, pledgets, ligatures. But all the ligatures and staves which shall be used for that purpose must be fastened to the Patients night-lap.

The use of a dry suture.

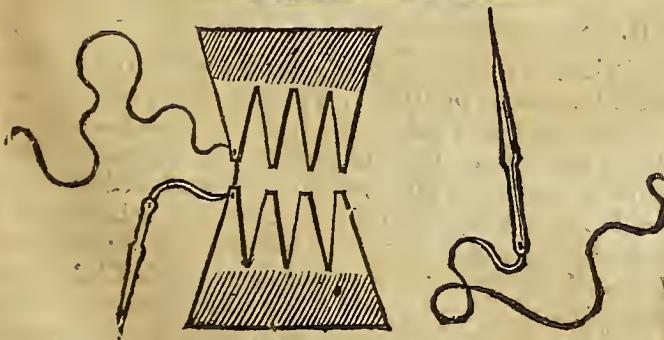

How to make a dry suture.

But when the wound is great and deep, and the lips thereof are much distant the one from the other, there can be no use of such a dry suture. Wherefore you must use a three or four square needle (that so it may the more readily and easily enter into the flesh) being thred with a waxed thred; and with this you must thrust through the lips of the wound, and leave the needle sticking in the wound, & then wrap the thred to and again over the ends thereof eight or ten times, just after that manner which women use to fasten a needle with thred in it, upon their sleeves, or Tailors to their hats or caps, that they may not lose them.

A Suture fit for hare-lips.

The manner thereof.

future is used in the wounds of the lips, as also in hare-lips, for so we commonly call lips which are cleft from the first conformation in the wombe by the error of the forming faculty. But such a future will help nothing to agglutination, if there lye or remain any skin between the lips of the

What hare lips are.

wound; Wherefore you shall cut away whatsoever thereof shall be there, otherwise you must expect no union. Other kind of sutures are of no great use in wounds of these parts, for out of the necessity of eating and speaking, they are in perpetuall motion; wherefore a third would cut the flesh; for which reason you shall take up much flesh with such Needles mentioned in this last described kind of Suture as this following figure shewes.

The figure of the suture fit for cloven or bare lips; as also the delineation of the Needle about whose ends the thred is wrapped over and under, 10 and again.

A History.

A decoction good to wash away putrefaction.

A small hole remaining after the cure of great wounds,

put the head of the pin; out whereof neverthelesse much serous and thin moysture flowed, especially when he either eat or spake; which I have also observed in many others. But for staying of this waterish humidity I dropped *Aqua fortis* into the bottome of the ulcer, and divers times put therein a little of the powder of burnt vitriol. Thus by Gods grace he recovered and became whole.

To this purpose I will recite a history, to the end, that if any such thing happen to come to your hands, you may do the like. A certain Gascoin in the battell at Saint *Laurence* had his upper jaw cut overthwart even to his mouth, to the great disfiguring of his face. The wound had many wormes in it and stank exceedingly, because he could get no Chirurgeon untill three dayes after he was hurt. Wherefore I washed it with a decoction of wormwood, Aloes, and a little *Ægyptiacum*, both to kill the wormes, and to fetch away all the putrid matter; I discussed the tumor with a dissolving fomentation and cataplasme, I joyned together the lips of the wound with the last described suture. But I applyed this following medicine to the whole part. *Re Terebinth. vcnnet. ʒvj. gummi elemi. ʒij. pulveris boli armeni, san. drac. Mastichs, myrrhæ, aloes, an. ʒß. incorporentur simul. fiat medicamentum.* The wound was agglutinated within a few dayes, but that there remained a certain little hole at the joyning of the lower jaw with the upper, wherein you could scarce

CHAP. XXVI. Of the wounds of the Nose.

How many wayes the nose may be hurt.

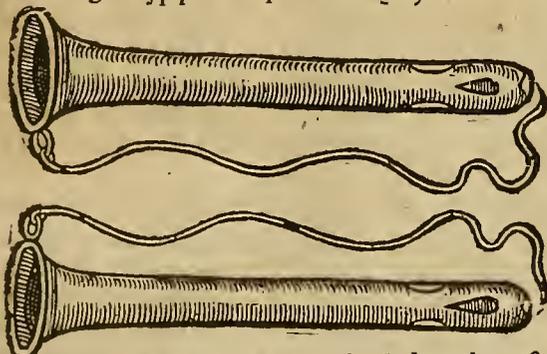

He Nose many wayes suffers solution of continuity; as by a wound, fracture and contusion, and it is sometimes battered & broken on the upper part; which when it happens, you shall restore the deprest bones to their native seat and figure, with the end of a *spatula* or fit stick wrapped about with towe, cotton or a linnen rag. Then with pledgets dipped in an astringent medicine composed *ex albumine ovi, mastich. bolo armeno, sanguin. drac. & Alumine usto*, and applyed to the side of the nose, he shall labour to strengthen the restored bones, and then bind them with a convenient ligature, which may not presse them too much, lest the nose should become flat, as it happens to many through the unskilfulness of Chirurgeons.

The cure of a broken nose.

The Figure of pipes to be put into the Nostrils.

The use of pipes in broken noses.

Then must you put little pipes into the nostrills, and these not exactly round, but somewhat flat and deprest, tyed to the night-cap on each side with a thred, lest they should fall out. By the help of these pipes the bones of the nose will be kept in their place, and there will be passage forth for the matter, and for inspiration and expiration. But if all the nose, or some portion thereof shall be wholly cut off, we must not hope to restore it. But if the Nose be so cut, that as yet it adheres to much of the adjacent flesh, from whence it may receive life and nourishment, then sow it up. For the

lower part of the nose it may be shaken, deprest and wrested aside, seeing it is griffly; but it cannot be broken as the other which is of a bony nature.

CHAP. XXVII. Of the Wounds of the Tongue.

How many wayes the continuity of the tongue may be loosed.

He tongue may be so wounded, that either it may be wholly cut off and deprived of some portion of the substance, or only slit long wayes or atwhart. The losse of the substance cannot be repaired, because every part separated and pluckt from the living body, from whence it had life, spirit and blood, presently dyes. For as the Philosophers say, *Privatione ad habitum non est regressus*. But when it is cut or slit long wayes or sidewayes, it is easily restored by suture, if so be that the cloven part yet adhere to the living body from whence it may draw both matter and form of life. Therefore a carefull servant shall straitly hold with a soft and clean linnen cloth the body of the tongue, lest it should slip away by reason of its slipperiness, whilst the Chirurgeon stich it above and below; when he thinks he hath sufficiently sowed it, let him cut off the thred as neer to the knot as he can, lest being left too long it might be tangled with the teeth as he eats, and so cause a hurtfull laceration or rending of the sowed parts. In the mean time let the patient eat barley creams, almond milks, Gellyes, cullisses and broths, and the yolks of eggs; and let him often hold in his mouth Sugar of Roses and syrup of Quinces; for such things besides their nourishing faculty, perform the part of an agglutinating and detergent medicine. I have learned these things I have here set down, neither from my masters whom I have heard with attention, nor by reading

The cure of a cloven tongue.

of books, but they have been such as I have tryed with happy success in many; as in the son of Monsieur de Marigny President of the Inquisition, in John Piet a Carpenter dwelling in the suburbs of Saint German.

But most apparently in a child of three years old, the son of the great Lawyer Monsieur Covet, who fell with his chin upon a stone, and so cut off a large pece of the end of his tongue, which chanced to be between his teeth, it hung but at a very small fiber of flesh, so that I had very little or no hope to agglutinate and unite it, which thing almost made me to pluck it quite away; yet I changed that determination by considering the loss of the most noble action of speaking, which would thereupon ensue, and weighing the providence of nature often working wonders and such things as exceed the expectation of the Phylitian in curing diseases. I also thought thus with my self, the flesh of the tongue is soft, loose, fungous and spongy, neither is it altogether obvious to the externall injuries of the ayr; wherefore after that I had once or twice thrust through the needle and thred upwards and downwards, and for the rest ordered the child to be used and dieted after the manner I lately mentioned, he grew well within a short time, and yet remains so, speaking well and distinctly.

A History.
Nature oft

the cure;
of diseases;

CHAP. XXVIII. Of the Wounds of the Eares.

THe eares are sometimes wholly cut off, sometimes but in part, otherwhiles they are only slit, so that the rent portion as yet adhering to the rest, is joynd with it in communion of life. In this last case it is fit to use a suture; but yet so that you touch not the gristle with your needle; for thence there would be in danger of a gangrene which happens to many by foolish curing; therefore you shall take up and comprehend with your needle only the skin, and that little flesh which encompasses the gristle. You shall perform the rest of the cure with pledgets and ligatures artificially fitted, and shall resist inflammation and other symptomes with fit medicins. But you must take speciall care that no superfluous flesh grow in the auditory passage, which may hinder the hearing; wherefore you shall keep that passage free by stopping it with a pece of sponge. But you shall procure agglutination and consolidation of the gristly part (and therefore next to a bone most dry) with dry medicins. But those who have their eares quite cut off, can do nothing but hide the deformity of their mis-hap with a cap, stuffed with cotton on that side.

CHAP. XXIX. Of the Wounds of the neck and throat.

THe Wounds of the neck and throat are somewhiles simple, as those which only use the continuity of the muscles; otherwhiles compound, such as those which have conjoynd with them a fracture of the bones, as of the *Vertebra*, or hurt of the internall and externall jugular Veins, or sleepey Arteries; sometimes the *Trachea Arteria*, or Weazon, and the *oesophagus* or gullet are wounded; sometimes wholly cut off, whence present death ensues. Wherefore let not the Chirurgion meddle with such wounds, unless he first foretell the danger of death, or the loss of some motion to those that are present. For it often happens that some notable nerve or tendon is violated by a wound in the neck, whence a palfie ensues, and that absolutely incurable, if the wound shall penetrate to the spinall marrow, also hurt therewith. Wounds of the gullet and Weazon are difficultly cured because they are in perpetuall motion; and chiefly of the latter by reason it is gristly and without blood. The wounds of the gullet are known, by spitting of blood, by the breaking forth of meat & drink by the wound; but if the gullet be quite cut asunder, the patient cannot swallow at all. For the cut parts are both contracted in themselves, the one upwards, and the other downwards. But we know the weazon is hurt, by casting up blood at the mouth with a continuall cough, and by the coming forth of the breath or winde by the Wound. The Wounds of the jugular Veins and sleepey Arteries, if they be great, are usually deadly, because they cannot be straitly bound up; for you cannot bind the throat hard without danger of choaking or strangling the patient. But for defect of a strait ligature in this case the flux of blood proves deadly. If the recurrent Nerve of either side be cut, it makes the voice hoarse; if cut on both sides, it takes away the use of speech, by hurting these instruments which impart motion to the muscles of the *Larynx*. For the cure if the wound be small, and not associated with the hurt of any notable vessel, nor of the Weazon and gullet, it is speedily and easily cured; and if there shall be need you shall use a suture, then you shall put therein a sufficient quantity of Venice Turpentine mixed with bole-Armenick; or else some of my Balsam of which this is the receipt. *R. Terebinth. venet. lb. ss. gum. elemi. ℥iij. olei hypericonis ℥ij. boli armeni. & sang. draconis an. ℥j. aqua vitæ ℥ij. liquefiant simul omnia lento igne, & fiat Balsamum ut artis est, addendo pulveris ireos florent. aloes, Mastiches, myrrhæ an. ℥j.* I have done wonders with this Balsame in the agglutination of simple wounds, wherein no strange body hath been. Now when you have put it in, lay upon it a plaister of *Diacalcitheos* dissolved in oyl of Roses & vinegar, as that which hath power to repress the flowing down of humors, and hinder inflammation, or in stead thereof you may apply *Emp. de Gratia Dei*, or *Emp. de Ianna*. But if the jugular veins and sleepey Arteries be cut, let the bleeding be stayed, as we have shewed in a chapter, treating thereof. When the Weazon or Gullet are wounded, the Chirurgion shall sow them up as neatly as he can, and the Patient shall not endeavour to swallow any hard thing, but be content to be fed with gellyes and brothis. When a gargarisine is needfull, this following is very good. *R. bordei M. j. storum rosar. p. j. passul. mund. jujubanum an. ℥β. ghyr hize ℥j. bulliant omnia simul, addendo mellis ros. & Iulep. ros. an. ℥ij. fiat gargarisina, ut artis est.*

With which being warm the Patient shall moisten his mouth, and throat, for it will mitigate the harshness of the part, assuage pain, cleanse and agglutinate, and make him breath more freely. But that the Chirurgion may not despaire of, or leave any thing unattempted in such like wounds, I have thought good to demonstrate by some examples how wonderfull the works of nature are, if they be assisted by Art.

thereof

A History. A certain servant of Monsieur de *Champagne*, a gentleman of *Anjou*, was wounded in the throat with a sword, whereby one of the jugular veins was cut together with his Weazon. He bled much and could not speak, and these symptoms remained, untill such time as the wound was sowed up, and covered with medicines. But if the medicins at any time were more liquid, he as it were sucked them by the wound and spaces between the stiches, and presently put forth at his mouth that which he had sucked or drawn in. Wherefore more exactly considering with my self, the greatnes of the Wound, the spermatick, and therefore dry and bloodless nature unapt to agglutination, of the affected part, but chiefly of the Weazon and jugular vein; as also for that the rough Artery is obnoxious to these motions which the gullet performs in swallowing, by reason of the inner coat, which is continued to the coat of the gullet, by which means these parts mutually serve each other with a reciprocall motion, even as the ropes which run to the wheel of a pulley; furthermore weighing that the Artery was necessary for the breathing, and tempering the heat of the heart, as the jugular veins served for the nourishment of the upper parts; and lastly weighing with my self the great quantity of blood he had lost, which is as it were the treasure of nature, I told those which were present, that death was neer and certainly at hand. And yet beyond expectation, rather by divine favour than our Art, he recovered his health.

A strange History. Equally admirable is this history following, Two Englishmen walked out of the City of *Paris* for their recreation to the wood of *Vincenne*; but one of them lying in wait to rob the other of his money and a massie chain of gold which he wore set upon him at unawares, cut his throat and robbed him, and so left him amongst the Vines which were in the way, supposing he had kill'd him, having with his dagger cut the Weazon and gullet. This murderer came back to the city; the other half dead, crawled with much adoe to a certain Peasants house, and being dressed with such medicines as were present and at hand, he was brought to the City, and by his acquaintance committed to my cure to be cured. I at the first, as diligently as I could, sowed up the Weazon which was cut quite asunder, and put the lips of the wound as close together as I could; I could not get hold of the gullet because it was fallen down into the stomach, then I bound up the wound with medicins, pledgets and sit ligatures. After he was thus drest he begun to speak, and tell the name of the villain the author of this fact, so that he was taken and fastened to the wheel, and having his limbs broken lost his wretched life, for the life of the innocent wounded man who dyed the fourth day after he was hurt.

Another History. The like hurt befell a certain Germane, who lay at the house of one *Perots* in the street of *Nuts*; he being frantick, in the night cut his throat with a sword: I being called in the morning by his friends who went to see him, drest him just after the same manner as I dressed the Englishman. Wherefore he presently recovered his speech, which before could not utter one syllable, freed from suspicion of the crime and prison the servant, who lying in the same chamber with him, was upon suspicion committed to prison, and confessing the thing as it was done, lived foure dayes after the wound being nourished with broths put into his fundament like clysters, and with the gratefull vapour of comfortable things, as bread newly drawn out of the Oven and soaked in strong wine. Having thus by Art of Chirurgery made the dumb speak for the space of foure dayes.

CHAP. XXX. Of the Wounds of the Chest.

The differences of wounds of the Chest.

Some wounds of the Chest are on the fore side, some behind, some penetrate more deep, others enter not into the capacity thereof, other some pierce even to the parts contained therein, as the *Mediastinum*, Lungs, heart, midriff, hollow vein, and ascendent artery; Other some passe quite through the body; whereby it happens that some are deadly, some not.

The signes. You shall thus know that the wound penetrates into the capacity of the Chest, if that when the patients mouth and nose be shut, the breath, or wind breaks through the wound with noise, so that it may dissipate, or blow out a lighted candle being held neer it. If the patient can scarce either draw, or put forth his breath, which also is a signe that there is some blood fallen down upon the *Diaphragma*.

Signes that the heart is wounded. By these signes you may know that the heart is wounded: If a great quantity of blood gush out, if a trembling possesse all the members of the body; if the pulse be little and faint, if the colour become pale, if a cold sweat and frequent fawning assail him, and the extreame parts become cold, then death's at hand.

A History. Yet when I was at *Turin* I saw a certain Gentleman who fighting a duell with another, received a wound under his left brest which pierced into the substance of his heart, yet for all that he struck some blowes afterwards, and followed his flying enemy some two hundred paces untill he fell down dead upon the ground; having opened his body, I found a wound in the substance of the heart, so large as would contain ones finger; there was only much blood poured forth upon the midriff.

Signes that the Lungs are wounded. These are the signes that the Lungs are wounded, for the blood comes foamy or frothy out of the wounds, the Patient is troubled with a cough, he is also troubled with a great difficulty of breathing and a pain in his side, which he formerly had not; he lyes most at ease when he lyes upon the wound, and sometimes it comes so to pass, that lying so he speaks more freely and easily, but turned on the contrary side, he presently cannot speak.

Signes that the midriff is wounded. When the *Diaphragma*, or midriff is wounded, the party affected is troubled with a weight or heaviness in that place, he is taken with a *Delirium*, or raving by reason of the sympathy of the Nerves of the sixth conjugation which are spread over the midriff; difficulty of breathing, a cough & sharp pain troubles the patient, the Guts are drawn upwards; so that it sometimes happens by the vehemence

vehemency of breathing, that the stomach and guts are drawn through the wound into the capacity of the Chest; which thing I observed in two.

The one of these was a Mason, who was thrust through the midst of the midriff, where it is nervous, A History and dyed the third day following. I opening his lower belly, and not finding his stomach, thought it a monstrous thing; but at length searching diligently, I found it was drawn into the Chest, through the wound which was scarce an inch broad. But the stomach was full of wind, but little humidity in it.

The other was called captain *Francis d'Alon* a Native of *Xantoigne*, who before *Robbell* was shot with a Musket Bullet, entering by the breast-bone neer to the sword-like Gristle, and passing through the fleshy part of the midriff, went out at the space between the fifth and sixth bastard ribs. The wound was healed up on the out side, yet for all that there remained a weaknes of the stomach, whereupon a pain of the guts like to the colick took him, especially in the Evening, and on the night; for which cause he durst not sup but very sparingly. But on the eighth month after, the pain raging more violently in his belly then it was accustomed, he dyed; though for the mitigating of the vehemency thereof *Simon Malmedy* and *Anthony du Val* both learned Physitians omitted no kind of remedy. The body of the diseased was opened by the skilfull Chirurgeon *James Guillemeau*, who found a great portion of the colick gut swelled with much wind gotten into the Chest, through the wound of the *Diaphragma*, for all it was so small that you could scarce put your little finger in thereat. But now let us return from whence we digressed. Another History.

We understand that there is blood poured forth into the capacity of the Chest by the difficulty of breathing, the vehemency of the increasing feaver, the stinking of the breath, the casting up of blood at the mouth, and other symptomes which usually happen to these who have putrefied and clotted blood poured out of the vessels into the belly, infecting with the filthy vapour of the corrupt substance, the parts to which it shall come. But also, unless the Patient cannot lye upon his back, he is troubled with a desire to vomit, and covets now and then to rise, whence he often falls into a swoon, the vitall faculty which sustains the body being broken and debilitated both by reason of the wound, and concreat or clotted blood; for so putting on the quality of poyson, it greatly dissipates and dissolves the strength of the heart. Signs that there is blood poured into the capacity of the Chest.

It is a sign the spinall marrow is hurt, when a Convulsion or Palsie, that is, a sodain loss of sense and motion in the parts thereunder, an involuntary excretion of the Urine and other excrements, or a totall suppression of them, seizes upon the Patient. When the hollow vein and great Artery are wounded, the Patient will dye in a short time, by reason of the sodain and abundant effusion of the blood and spirits, which intercepts the motion of the Lungs and heart, whence the party dyes suffocated. Signs that the spine is wounded.

CHAP. XXX. Of the cure of the Wounds of the Chest.

WE have read in *Iohn de Vigo*, that it is disputed amongst Chirurgeons concerning the consolidation of wounds of the Chest. For some think that such wounds must be closed up, and cicatrized with all possible speed, lest the cold air come to the heart, and the vitall spirits fly away and be dissipated. Others on the contrary think that such wounds ought to be long kept open; and also if they be not sufficiently large of themselves, that then they must be enlarged by surgery, that so the blood poured forth into the capacity of the Chest may have passage forth, the which otherwise by delay would putrefie, whence would ensue an increase of the feaver, a fistulous ulcer, and other pernicious accidents. The first opinion is grounded upon reason and truth, if so be that there is little or no blood poured forth into the capacity of the Chest; But the latter takes place where there is much more blood contained in the empty spaces of the Chest. Which, lest I may seem rashly to determin, I think it not amiss to ratifie each opinion with a history thereto agreeable. Vigo tract. de vuln. thoracae. 10.

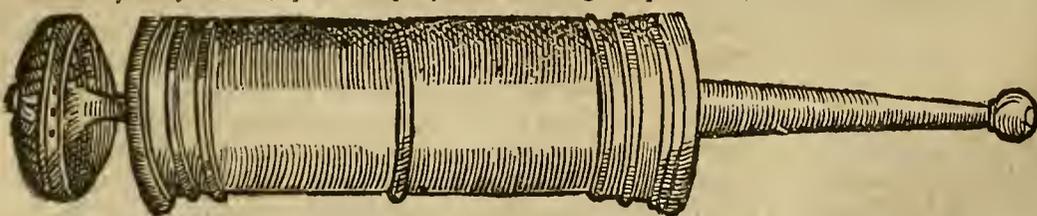

Whilst I was at *Turin*, Chirurgeon to the Marshall of *Montejan*, the King of *France* his Generall, A History I had in cure a Souldier of *Paris*, whose name was *Levesque*, he served under captain *Renovart*. He had three wounds, but one more grievous than the rest, went under the right breast, somewhat deep into the capacity of the Chest, whence much blood was poured forth upon the midriff, which caused such difficulty of breathing, that it even took away the liberty of his speech; besides through this occasion he had a vehement feaver, coughed up blood, and a sharp pain on the wounded side. The Chirurgeon which first dressed him, had so bound up the wound with a strait and thick suture, that nothing could flow out thereat. But I being called the day after, and weighing the present symptomes which threatned speedy death, judged that the sowing of the wound must straight be loosed; which being done there instantly appeared a clot of blood at the orifice thereof, which made me to cause the Patient to lye half out of his bed, with his head downwards, and to stay his hands on a settle which was lower than the bed, and keeping himself in this posture, to shut his mouth and nose that so his Lungs should swell, the midriff be stretched forth, and the intercostall muscles and those of the *Abdomen* should be compressed, that the blood poured into the Chest might be evacuated by the wound; but also that this excretion might succeed more happily, I thrust my finger somewhat deep into the wound, that so I might open the orifice thereof being stopped up with the congealed blood; and certainly I drew out some seven or eight ounces of putrefied & stinking blood by this means. When he was laid in his bed, I caused frequent injections to be made into the wound of a decoction of Barly with Honey of Roses and red Sugar, which being injected I wisht him to turn first on the one, and then on the other side, and then, again to lye out of his bed as before: for thus he evacuated smal, but very many clots of blood, together with the liquor lately injected; which being done, the symptomes were mitigated, & left him by little and little. The next day I made another more detergent injection, adding thereto wormwood, centaury, and Aloes; but such a bitternes did rise up to his mouth together with a desire to cast, that he could not longer indure it. Then it came into my mind that formerly I had observed the like effect of the like remedy in the Hospital. Why bitter things must not be cast into the Chest.

spitall of *Paris*, in one who had a fistulous ulcer in his Chest. Therefore when I had considered with myself that such bitter things may easily pass into the Lungs, and so may from thence rise into the Wæzon and mouth, I determined that thence forwards I would never use such bitter things to my Patients, for the use of them is much more troublesome than any way good and advantagious. But at the length this Patient by this and the like means recovered his health beyond my expectation.

But on the contrary, I was called on a time to a certain *German* gentleman who was run with a sword into the capacity of his Chest, the neighbouring Chirurgeon had put a great tent into the wound at the first dressing, which I made to be taken forth, for that I certainly understood there was no blood poured forth into the capacity of the Chest because the Patient had no fever, no weight upon the *Diaphragma*, nor spitted forth any blood. Wherefore I cured him in few dayes by only dropping in some of my balsame and laying a plaister of *Diacalctheos* upon the wound. The like cure I have happily performed in many others. To conclude, this I dare boldly affirm, that wounds of the Chest by the too long use of tents degenerate into *Fistula's*. Wherefore if you at any time shall undertake the cure of wounds which penetrate into the capacity of the Chest, you shall not presently shut them up at the first dressing, but keep them open for two or three dayes; but when you shall find that the Patient is troubled with none or very little pain, and that the midriff is pressed down with no weight, and that he breaths freely, then let the tent be taken forth, and the wound healed up as speedily as you can by covering it only with lint dipped in some balsame which hath a glutinative faculty, and laid somewhat broader than the wound; never apply liniments to wounds of this kind, lest the Patient by breathing draw them into the capacity of the Chest. Wherefore also you must have a care that the tent put into those kinds of wounds may be fastened to the pledgets, and also have somewhat a large head, lest they should be drawn as we said into the capacity of the Chest, for if they fall in, they will cause putrefaction and death. Let *Emplast. Decalctheos* or some such like be applied to the wound. But if on the contrary, you know by proper, and certain signs, that there is much blood fallen into the spaces of the Chest, then let the orifice of the wound be kept open with larger tents, untill all the *Sanies* or bloody matter, wherein the blood hath degenerated, shall be exhausted. But if it happen at any time, as assuredly it sometimes doth, that notwithstanding the Art and care of the Physitian, the wound degenerates into a *Fistula*, then the former evill is become much worse. For *Fistula's* of the Chest, are scarce cured at any time, and that for divers causes. The first is, for that the muscles of the Chest are in perpetuall motion; Auother is, because they on the contrary inside are covered only with the membrane investing the ribs, which is without blood. The third is, for that the wound hath no stay, by means whereof it may be compressed, sowed, and bound, whereby the lips being joyned together, the wound may at length be replenished with flesh and cicatrized.

But the reason why wounds of the Chest do every day heap up and pour forth so great a quantity of matter, seems to be their vicinity to the heart, which being the fountain of blood, there is a perpetuall efflux thereof from thence to the part affected. For this is nature's care in preserving the affected parts, that continually and abundantly without measure or mean it sends all its supplies, that is, blood and spirits to the aid. Add hereto, that the affected parts by pain, heat, and continuall motion of the Lungs and midriff, draw and allure much blood to themselves. Such like blood defiled by the malignity and filth of the wound, is speedily corrupted; whence it is that from the perpetuall afflux of blood, there is a continuall efflux of matter or filth, which at the last brings a man to a consumption; because the ulcerated part like a ravenous wolf consumes more blood by the pain, heat and motion than can be ministered thereto by the heart. Yet if there be any hope to cure and heal the *Fistula*, it shall be performed, (after the use of diet, phlebotomy, and according to the prescript of the Physitian) by a vulnerary potion, which you shall find described when we treat of the *Caries* or rottenness of the bones. Wherefore you shall make frequent injections therewith into the *Fistula*, adding and mixing with it *Syrupus de rosis siccis* and *mel rosarum*. Neither do I, if the putrefaction be great, fear to mix therewith *Ægyptiacum*. But you must have a care to remember & observe the quantity of the injected liquor, that you may know whether it all come forth again after it hath performed its detergent office. For if any thereof remain behind in the corners and crooked passages, it hurts the part, as corrupted with the contagion thereof,

The form of a Syringe fit to make injection, when a great quantity of liquor is to be injected into any part.

After the injected liquor is come forth, a pipe of gold, silver or lead, shall be put into the fistulous

ulcer; and it must have many holes in it, that so the filth may pass forth at them; it must be fast tyed with strings, that it may not fall into the capacity of the Chest. A great sponge steeped in *aqua vite*, and wrung forth again, shall be laid hot to the end or orifice thereof, both to hinder the entrance of the air into the *Fistulous* ulcer, as also to draw forth the filth there by its gentle heat, the which thing the Patient shall much further if often times both day and night he hold his breath, stopping his mouth and nose, and lying upon the diseased side, that so the *Sanies* may be the more forcibly evacuated; neither must we leave the putting in the pipe, before that this fistulous ulcer shall be almost dry, that is, whole, as when it yeelds little, or no matter at all; then it must be cicatrized. But if the orifice of this fistulous ulcer being in the upper part hinder the healing thereof, then by a chirurgicall Section, a passage shall be made in the bottome, as we said before in an *Empyema*.

The

Read the History of *Maryllus* in *Galen. lib. 7. de Anatom. administra.*

What harm ensues the too long use of tents.

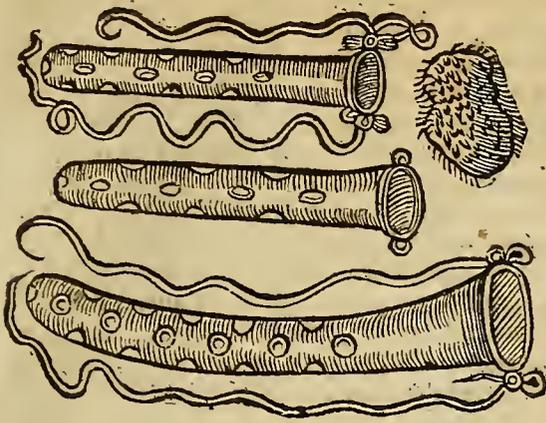

No liniments must be used in wounds of the Chest.

Wounds of the Chest easily degenerate into a *Fistula*.

Why there flows such plenty of matter out of wounds of the Chest.

The cure of a *Fistula* in the Chest. When *Ægyptiacum* must be put into the injections.

The delineation of the pipes with their strings and sponges.

The Reader must note that the pipes which are fit for this use, need not have so many holes as these here express; but only two or three in their ends: for the flesh growing and getting into the rest, make them that they cannot be plucked forth without much pain.

A wound made in the Lungs admits cure, unless it be very large, if it be without inflammation; if it be on the skirts of the Lungs, and not on their upper parts; if the Patient contain himself from coughing much, and contentious speaking, and great breathing: for the wound is enlarged by coughing, and thence also arises inflammation; the Pus and Sanies whereof, whilst the lungs again endeavour to expell by coughing, by which means they are only able to expell that which is hurtfull and troublesome to them, the ulcer

What wounds of the Lungs are curable.

The harm that infues upon coughing in wounds of the Lungs. How Eclegma's must be swallowed.

is dilated, the inflammation augmented, the Patient wastes away, and the disease becomes incurable.

There have bin many *Eclegma's* described by Physitians for to cleanse the ulcer, which when the Patient useth, he shall lye on his back, to keep them long in his mouth, so to relax the muscles of the *Larynx*; for thus the medicine will fall by little and little alongst the coats of the weazon, for if it should fall down in geeat quantity, it would be in danger to cause coughing. Cows, Asses, or Goats milk with a little hony, lest they should corrupt in the stomach, are very fit remedies for this purpose; but womans milk exceeds the rest.

But Sugar of Roses is to be preferred before all other medicines, in the opinion of *Avicen*, for that it hath a detergent, and also an astringent and strengthening faculty, than which nothing is more to be desired in curing of ulcers. When you shall think it time to agglutinate the clenfed ulcer, you must command the Patient to use emplastick, austere, and astringent medicines, such as are *Terra squillata*, *bolus armenus*, *hypocystis*, plantain, knot-grass, *Sumach*, *acacia* and the like, which the Patient shall use in his broaths and *Eclegma's*, mixing therewith honey of roses, which serving for a vehicle to the rest, may carry away the impacted filth which hinders agglutination. But seeing an hective feaver easily follows upon these kinds of wounds, and also upon the affects of the Chest and lungs, it will not be amiss to set down somewhat concerning the cure thereof, that so the Chirurgion may know to administer some help to his Patient, whilst a Physitian is sent for, to overcome this disease with more powerfull and certain remedies.

The utility of Sugar of roses in ulcerated or wounded Lungs.

CHAP. XXXII. Of the differences, causes, signs and cure of an Hective Feaver.

Hective feaver is so called, either for that it is stubborn and hard to cure and loose, as things which have contracted a habit; for *Hexis* in Greek signifies a habit; or else for that it seizes upon the solid parts of our bodies called by the Greeks *Hexeis*; both which the Latin word *Habitus* doth signifie.

The reason of the name.

There are three kinds, or rather degrees of this feaver. The first is when the hectick heat consumes the humidity of the solid parts. The second is, when it feeds upon the fleshy substance. The third and incurable is, when it destroyes the solid parts themselves. For thus the flame of a lamp first wastes the oyl, then the proper moisture of the weik. Which being done there is no hope of lighting it again what store of oyl soever you poure upon it. This feaver very seldome breeds of it self, but commonly follows after some other.

The differences thereof.

Wherefore the causes of a hective feaver are, sharp and burning feavers not well cured, especially if their heat were not repressed with cooling epithemes applyed to the heart and *Hypochondria*. If cold water was not fitly drunk. It may also succeed a Diary feaver which hath been caused and begun by some long, great, and vehement grief or anger, or some too violent labour, which any of a slender and dry body hath performed in the hot sun. It is also oft-times caused by an ulcer or inflammation of the Lungs, an *empyema* of the Chest, by any great and long continuing *Phlegmon* of the Liver, stomach, mesentery, wombe, kidneys, Bladder, of the guts *Iejunum* and *Colon*, and also of the other Guts, if the *Phlegmon* succeede some long *Diarrhaea*, *Lienteria* or bloody flux, whence a consumption of the whole body, and at last a hectick feaver, the heat becoming more acrid, the moisture of the body being consumed.

The causes.

This kind of feaver as it is most easily to be known, so is it most difficult to cure; the pulse in this feaver is hard, by reason of the dryness of the Artery which is a solid part; and it is weak by reason of the debility of the vitall faculty, the substance of the heart being assaulted. But it is little and frequent because of the distemper and heat of the heart, which for that it cannot by reason of its weakness cause a great pulse to cool it self, it labours by the oftensness to supply that defect.

The Signs.

But for the pulse, it is a proper sign of this feaver, that one or two houres after meat the pulse feels stronger than usuall; and then also there is a more acrid heat over all the Patients body. The heat of this flame lasts untill the nourishment be distributed over all the Patients body; in which time the dryness of the heart in some sort tempered and recreated by the appulse of moist nourishment, the heat increases no otherwise than lime which a little before seemed cold to the touch, but sprinkled and moistened with water grows so hot, as it smoaks and boyls up. At other times there is a perpetuall equality of heat & pulse in smalness, faintness, obscurity, frequency, and hardness, without any exacerbation, so that the Patient cannot think himself to have a feaver, yea he cannot complain of any thing, he feels no pain, which is another proper sign of an hectick feaver. The cause that the heat doth not

shew its self is, it doth not possess the surface of the body, that is, the spirits and humors, but lyes as buried in the earthy grossness of the solid parts. Yet if you hold your hand somewhat long, you shall at last perceive the heat more acrid and biting, the way being opened thereto by the skin rarified by the gentle touch of the warm and temperate hand. Wherefore if at any time in these kind of feavers the Patient feel any pain, and perceive himself troubled with an inequality and excess of heat, it is a sign that the hectick feaver is not simple, but conjoined with a putrid feaver, which causeth such inequality, as the heat doth more or lesse seise upon matter subject to putrefaction; for a hectick feaver of itself is void of all equality, unless it proceed from some external cause, as from meat; Certainly if an Hippocratic face may be found in any disease, it may in this, by reason of the colliquation, or wasting away the triple substance. In the cure of this disease, you must diligently observe with what affects it is entangled, and whence it was caused. Wherefore first you must know whether this feaver be a disease; or else a symptome. For if it be symptomaticall, it cannot be cured, as long as the disease the cause thereof, remains uncured; as if an ulcer of the guts occasioned by a bloody flux shall have caused it, or else a fistulous ulcer in the Chest caused by some wound received on that part, it will never admit of cure, unless first the fistulous or dysenterick ulcer shall be cured; because the disease feeds the symptomes, as the cause the effect. But if it be a simple and essential hectick feaver, for that it hath its essence consisting in an hot and dry distemper, which is not fixed in the humors, but in the solid parts, all the counsell of the Physitian must be to renew the body, but not to purge it; for only the humors require purging, and not the defaults of the solid parts. Therefore the solid parts must be refrigerated and humected; which we may doe by medicins taken inwardly and applyed outwardly.

The things which may with good success be taken inwardly into the body for this purpose, are medicinall nourishments. For hence we shall find more certain and manifest good, than from altering medicins, that is, wholly refrigerating and humecting without any manner of nourishment.

For by reason of that portion fit for nutriment which is therewith mixed they are drawn and carried more powerfully to the parts, and also converted into their substance: whereby it comes to passe that they do not humect and coole them lightly and superficially, like the medicins which have only power to alter and change the body, but they carry their qualities more thoroughly even into the innermost substance. Of these things some are herbs, as violets, purslain, bugloss, endive, ducks-meat, or water lentill, mallowes, especially when the belly shall be bound. Some are fruits, as gourds, cowcubers, apples, prunes, raisons, sweet almonds, and fresh or new pine-apple kernells; in the number of seeds are the foure greater and lesser cold seeds, and these new, for their native humidity, the seeds of poppyes, berberies, quinces. The flowers of bugloss, violets, water lillies, are also convenient; of all these things let broth be made with a chicken, to be taken in the morning for eight or nine dayes, after the first concoction.

For meats; in the beginning of the disease, when the faculties are not too much debilitated, he shall use such as nourish much and long, though of hard digestion; such as the extreame parts of beasts, as the feet of Calves, Hogs feet not salted, the flesh of a Tortois, which hath lived so long in a garden, as may suffice to digest the excrementitious humidity; the flesh of white Snails, and fish as have been gathered in a vineyard, of frogs, river Crabs, Eels taken in clear waters, and well cooked, hard eggs eaten with the juyce of Sorrell without spices; Whitings and stockfish. For all such things because they have a tough and glutinous juice, are easily put and glutinated to the parts of our body, neither are they so easily dissipated by the feaverish heat. But when the patient languisheth of a long hectick, he must feed upon meats of easie digestion, and these boyled rather than roasted; for boyled meats humect more, & roasted more easily turn into choler. Wherefore he may use to eat Veal, Kid, Capon, Pullet, boyled with refrigerating and humecting hearbs; he may also use Barly creams, Almond milks, as also bread crummed and moistened with rose water and boyled in a decoction of the foure cold seeds with sugar of roses; for such a Panada cools the liver, and the habit of the whole body, & nourisheth withall. The Testicles, wings, and livers of young cocks, as also figs and raisons. But if the Patient at length begin to loath and grow weary of boyled meats, then let him use roast, but so that he cut away the burnt & dried part thereof, and feed only on the inner part thereof, & that moistned in rose water, the juice of Citrons, Oranges or Pomegranats. Let him abstain from salt and dry fishes, and chuse such fishes as live in stony waters, for the exercise they are forc'd to undergoe in shunning the rocks beaten upon by the waves. Asses milk newly milked and seasoned with a little salt, sugar, honey, or fennell, that it may not corrupt, nor grow sowre in the stomach; or womans milk suckt from the dug by the Patient, to the quantity of halfe a pint, is much commended; verily womans milk is the more wholsome, as that which is more sweet and familiar to our substance, if so be that the nurse be of a good temper and habit of body. For so it is very good against the gnawings of the stomach, and ulcers of the Lungs, from whence a Consumption often proceeds. Let your milch Ass be fed with barly, oats, oakleaves; but if the Patient chance to be troubled with the flux of the belly, you shall make the milk somewhat astringent by gently boiling it, and quenching therein pebble stones heated red hot. But for that all natures cannot away with Asses milk, such shall abstain from it, as it makes to have acrid belchings, difficulty of breathing, a heat and rumbling in the *Hypochondria*, and pain of the head. Let the Patient temper his wine with a little of the waters of Lettuce, purslain and water-lillies, but with much bugloss water, both for that it moistens very much, as also for that it hath a specifick power to recreate the heart, whose solid substance in this kind of disease is grievously afflicted. And thus much of things to be taken inwardly.

These things which are to be outwardly applyed, are ununctuous, baths, epithemes, clysters. Ununctious are divers, according to the various indication of the parts whereto they are applyed. For *Galen* anoints all the spine with cooling and moderate astringent things, as which may suffice to streng- then

then the parts, and hinder their waſting, & not let the tranſpiration; for if it ſhould be letted, the heat would become more acrid, by ſuppreſſing the vapours. Oyl of roſes, water lillies, Quinces, the mucilages of Gum tragacanth and arabick extracted into water of nightſhade, with ſome ſmall quantity of canphire, and a little wax if need require; but on the contrary, the parts of the breaſt muſt be annointed with refrigerating and relaxing things; by refrigerating I mean things which moderately cool, for cold is hurtfull to the breaſt. But aſtringent things would hinder the motion of the muſcles of the cheſt, and cauſe a difficulty of breathing. Such inunctions may be made of oyl of Violets, willowes, of the ſeeds of lettuce, poppies, water-lillies, mixing with them the oyl of ſweet almonds to temper the aſtriction which they may have by their coldneſs. But you muſt have great care that the Apothecary for covetouſneſs in ſtead of theſe oyls newly made give you not old, rancid and ſalted oyls, for ſo in ſtead of refrigerating, you ſhall heat the part; for wine, honey and oyl acquire more heat by age; in defect of convenient oyls, we may uſe butter well waſhed in violet and nightſhade water. The uſe of ſuch inunctions, is to cool, humect and comfort the parts whereto they are uſed; they muſt be uſed evening and morning, chiefly after a bath.

A caution
in the
choice of
Oyles.

Now for Baths, we preſcribe them either only to moiſten, and then plain warm water wherein the flowers of Violets and water lillies, willow leaves and barley have been boyled, will be ſufficient; or

The diffe-
rences of
Baths.

elſe not only to moiſten, but alſo to acquire them a fairer and fuller habit, and then you may adde to your bath the decoction of a ſheeps head and Gather, with ſome butter. But the Patient ſhall not enter into the bath faſting, but after the firſt concoction of the ſtomach, that ſo the nourishment may be drawn by the warmneſs of the bath into the whole habit of the body, for otherwiſe he which is ſick of a conſumption and ſhall enter the bath with his ſtomach empty, ſhall ſuffer a greater diſſipation of the triple ſubſtance, by the heat of the bath, then his ſtrength is well able to endure. Wherefore it is fit thus to prepare the body, before you put it into the bath. The day before in the morning let him take an emollient clyſter, to evacuate the excrements baked in the guts by the heſtick dryneſs; then let him eat to his dinner ſome ſolid meats about nine of the clock; and let him about foure of the clock eat ſomewhat ſparingly, meats of eaſie digeſtion to his ſupper. A little after midnight let him ſup off ſome chicken broth or barley cream, or elſe two rear eggs tempered with ſome roſe water and ſugar of roſes in ſtead of ſalt. Some 4 or 5 houres after, let him enter into the bath, theſe things which I have ſet down, being obſerved. When he comes out of the bath, let him be dried and gently rubbed, with ſoft linnen cloaths, and anointed as I formerly preſcribed, then let him ſleep if he can for two or three houres in his bed: when he wakes let him take ſome Ptisan, or ſome ſuch like thing, and then repeat his bath after the foreſaid manner. He ſhall uſe this bath thrice in ten dayes; But if the Patient be ſubject to crudities of the ſtomach, ſo that he cannot ſit in the bath without fear of ſowning and ſuch ſymptomes, his ſtomach muſt be ſtrengthened with oyl of Quinces, Wormwood and maſſich, or elſe with a cruſt of bread toſted, and ſteeped in muſkadine, and ſtrewed over with the powders of Roſes, Sanders, and ſo laid to the ſtomach, or behind near to the thirteenth vertebra of the back, under which place, Anatomy teaches, that the mouth of the ſtomach lyes. Epithemes ſhall be applyed to the liver and heart, to temper the too acrid heat of theſe parts, and correct the immoderate dryneſs by their moderate humidity. Now they ſhall be made of refrigerating and humecting things, but chiefly humecting; for too great coldneſs would hinder the penetration of the humidity into the part lying within. The waters of bugloſs, and Violets, of each a quartern with a little white wine is convenient for this purpoſe. But that which is made of French barley, the ſeeds of gourds, pompions, or Cowcumpers of each three drams in the decoction, and mixed with much tempering with oyl of Violets, or of ſweet almonds, is moſt excellent of all other. Let cloaths be dipped and ſteeped in ſuch epithemes, and laid upon the part, and renewed as oft as they become hot by the heat of the part. And becauſe in heſtick bodies, by reaſon of the weakneſs of the digeſtive faculty, many excrements are uſually heaped up, and dried in the guts, it will be convenient, all the time of the diſeaſe to uſe frequently clyſters made of the decoction of cooling and humecting herbs, flowers, and ſeeds wherein you ſhall diſſolve *Caffia* with ſugar and oyl of Violets, or water-lillies. But becauſe there often happen very dangerous fluxes in a confirmed heſtick fever, which ſhew the decay of all the faculties of the body, and waſting of the corporeall ſubſtance, you ſhall reſiſt them with refrigerating and aſſiſting medicins; and meats of groſſer nourishment, as Rice, and Cicers; and application of aſtringent and ſtrengthening remedies; and uſing the decoction of Oats or parched barley for drink. Let the Patient be kept quiet and ſleeping as much as may be, eſpecially if he be a child. For this fever frequently invades children by anger, great and long fear, or the two hot milk of the nurſe, overheating in the Sun, the uſe of wine and other ſuch like cauſes; they ſhall be kept in a hot and moiſt ayre, have another Nurſe, and be anointed with oyl of violets; to conclude, you ſhall apply medicins which are contrary to the morbiſick cauſe.

C. H A P. XXXIII. *Of the wounds of the Epigaſtrium and of the whole lower belly.*

The wounds of the lower belly are ſometimes before, ſometimes behind, ſome only touch the ſurface thereof, others enter in; ſome paſſe quite through the body, ſo that they often leave the weapon therein; ſome happen without hurting the contained parts; others grievouſly offend theſe parts, the liver, ſpleen, ſtomach, guts, kidneys, womb, bladder, ureters, and great veſſels, ſo that oft-times a great portion of the Kall, falls forth. We know the Liver is wounded, when a great quantity of blood comes forth of the wound, when a pricking pain reaches even to the ſword-like griffle, to which the Liver adheres. Oft-times more choler is caſt up by vomit, and the Patient lyes on his belly with more eaſe and content.

Their diffe-
rences.

Signs of a
wounded
liver.

Signs that
the ſto-
mach and
ſmaller guts
are wound-
ed.

When the ſtomach or any of the ſmall guts are wounded, the meat & drink break out at the wound, the *Ilia* or flanks ſwell and become hard, the hicket troubles the Patient, and oft-times he caſts up more

cholera, and grievous pain wrings his belly, and he is taken with cold sweats, and his extreame parts wax cold.

If any of the greater guts shall be hurt, the excrements come forth at the wound: When the Spleen is wounded, there flows out thick and black blood, the Patient is oppressed with thirst, and there are also the other signs, which we said use to accompany the wounded Liver. A difficulty of making water troubles the Patient whose reins are wounded, blood is pissed forth with the Urine, and he hath a pain stretched to his groins and the regions of the Bladder and Testicles.

The Bladder or Ureters being wounded, the flanks are pained, and there is a Tension of the *Pecien* or share, blood is made in stead of urine, or else the urine is very bloody, which also divers times comes forth at the wound. When the wombe is wounded, the blood breaks forth by the privities, and the Symptomes are like those of the Bladder.

The wounds of the liver are deadly, for this part is the work-house of the blood, wherefore necessary for life; besides by wounds of the liver the branches of the Gate or Hollow veins are cut, whence ensues a great flux of blood not only inwardly, but also outwardly, and consequently a dissipation of the spirits and strength.

But the blood which is shed inwardly amongst the bowels putrefies and corrupts, whence follows pain, a fever, inflammation, and lastly death. Yet *Paulus Aegineta* writes, that the lobe of the Liver may be cut away without necessary consequence of death. Also the wounds of the Ventricle and of the small Guts, but chiefly of the *Iejunum* are deadly; for many vessells run to the *Iejunum* or empty Gut, and it is of a very nervous and slender substance, and besides it receives the cholerick humor from the bladder of the Gall. So also the wounds of the Spleen, Kidneys, Ureters, Bladder, Womb and Gall, are commonly deadly, but always ill, for that the actions of such parts are necessary for life; besides, divers of these are without blood and nervous others of them receive the moist excrements of the whole body, and lye in the innermost part of the body, so that they do not easily admit of medicins. Furthermore, all wounds which penetrate into the capacity of the belly, are judged very dangerous, though they do not touch the contained bowels; for the encompassing and new ayr entring in amongst the bowels, greatly hurts them, as never used to the feeling thereof; adde hereto the dissipation of the spirits which much weakens the strength. Neither can the filth of such wounds be wasted away according to the mind of the Chirurgion, whereby it happens, they divers times turn into fistula's, as we said of wounds of the Chest, and so at length by collection of matter cause death. Yet I have dressed many who by Gods assistance & favour have recovered of wounds passing quite through their bodies.

I can bring as a witness the steward of the Portingall Embassadour, whom I cured at *Melum*, of a wound made with a sword so running through his body, that a great quantity of excrements came forth of the wounded Guts, as he was a dressing, yet he recovered.

Not long agoe *Giles le Maistre* a Gentleman of *Paris* was run quite through the body with a Rapier, so that he voided much blood at his mouth and fundament divers dayes together, whereby you know the Guts were wounded; and yet he was healed in twenty dayes. In like sort the wounds of the greater vessells are mortall, by reason of the great effusion of blood and spirits which ensues thereupon.

C H A P. XXXIII. The cure of wounds of the lower belly.

He first cogitation in curing of these wounds ought to be whether they pierce into the capacity of the Belly; for those which passe no further than the *Peritonaeum* shall be cured like simple wounds which only require union. But those which enter into the capacity must be cured after another manner. For oft times the Kall or Guts, or both fall forth at them.

A gut which is wounded must be sowed up with such a seam as Furriers or Glovers use, as we formerly told you; and then you must put upon it a powder made of Mastich, Myrrh, Aloes and Bole. Being sowed up, it must not be put up boysterously together and at once into its place, but by little and little, the Patient lying on the side opposite to the wound. As for example, the right side of the Guts being wounded and falling out by the wound, the Patient shall lye on his left side, for the more easy restoring of the fallen down Gut, and so on the contrary. If the lower part of the Guts being wounded slide through the wound, then the Patient shall lye with his head low down, & his buttocks raised up by putting a pillow under them; If the upper part be hurt, then must he lye quite contrary, that the Guts falling downwards by such a site, may give way to these which are fallen out through the wound. But often in this case, the Guts having taken cold by the encompassing ayre, swell up and are distended with wind, the which you must discuss before you put them into their place, with a fomentation of the decoction of camomill, melilot, aniseeds and fennell applyed with a sponge, or contained in a bladder; or else with chickens, or whelps cut alive in the midst and laid upon the swelling; for thus they do not only discuss the flatulency, but also comfort the afflicted part. But if the inflation cannot thus be discussed, the wound shall be dilated, that so the Guts may return the more freely to their place.

If the Kall shall fall out, it must be speedily restored to its place, for it is very subject to putrefie; for the fat, whercof for the most part it consists, being exposed to the ayre, easily loses its native heat, which is small and weak, whence a mortification ensues. Hence is that of *Hippocrates*; If the Kall fall out, it necessarily putrefies. The Chirurgion shall know whether it putrefies, or not, by the blacknesse and the coldness you may perceive by touching it; neither must you when it putrefies presently restore it to its place, for so the contagion of the putrefaction would spread to the rest of the parts: but whatsoever thereof is putrefied shall be twitched and bound hard with a string and so cut off, and the rest restored to his proper place: but it's good after cutting of it away to leave the string still hanging thereat, that so you may pluck and draw forth whatsoever thereof may by being too strait bound fall away into the capacity of the belly. Some think it to be better to let the Kall thus bound to hang forth until

A History.

Another History.

The cure of a wounded Gut.

The cure when the Kall falls out. Hip. Aph. 58. sect. 6.

till that portion thereof which is putrefied fall away of it self, and not to cut it off. But they are much deceived, for it hanging thus would not cover the guts, which is the proper place. The Guts and Kall being put up, if the wound be great and worth speaking of, it must be sowed with that suture which is termed *Gastroaphia*; but this kind of suture is thus made. The needle at the first putting in must only take hold of the *Peritonæum*, and then on the opposite side only of the flesh, letting the *Peritonæum* alone, & so go along putting the needle from without inwards, and from within outwards, but so that you only take the musculous flesh & skin over it, & then only the *Peritonæum*, until you have sowed up all the wound. He which doth otherwise shall undergo this danger, that whereas the coat *Peritonæum* is of it self without blood, it being divided, or wounded cannot of it self be united to it self, therefore it requires an intercourse of flesh: otherwise unless it be thus united by the benefit, of the flesh intermixed therewith, there would remain an incurable tumor after the wound is cicatrized on the outside. But that which we said before according to *Galens* mind, that all the wounds must be sowed, it is not so to be taken as if that the wound must be sowed up to the very end; for in the lower part of the wound there must be left a certain small vent by which the quittance may pass forth, which being wholly cleansed and exhausted, the wound must be quite healed up. But the wounds which shall penetrate into the substance of the liver, spleen, ventricles, and other bowells, the Chirurgeon shall not suffer them to be without medicines as if they were desperate, but here shall spare neither labour nor care to dress them diligently. For doubtfull hope is better then certain despair. The bladder, womb, & right gut being wounded, detergent and agglutinative injections shall be put up by their proper passages. I have read nothing as yet in any Author of the wounds of the fat, for all of them refer the cure thereof to the wounds of the Muscles. Yet I wil say this by the way, that wounds of the fat how deep soever they be, if they be only simple, may be dressed without putting in of any Tent, but only dropping in some of my balsam, and then laying upon it a plaister of *Gratia Dei*, or some such like, for so they will heal in a short time.

Lib. 5. Meth.
cap. 4.

The cure of
the wound-
ed fat.

CHAP. XXXV. *Of the wounds of the Groins, Yard and Testicles.*

When the Groins and neighbouring parts are wounded, we must first consider whether they pierce to within: and if they do penetrate, to what inward parts they come, whether to the bladder, the womb, or right gut: for these parts are such neer neighbours that oft-times they are all wounded with one blow. But for the wounds of the Testicles, and genitall parts, because they are necessary instruments for the preserving the species by generation, or a succession of individualls, and to keep all things quiet at home, therefore the Chirurgeon ought to be very diligent and carefull for their preservation. Wherefore if they should chance at any time to be wounded, they shall be dressed as we have formerly delivered, the medicines being varied according to the state of the wound, and the appearing and happening symptomes; for it would be a thing of immense labour to handle all things in particular.

CHAP. XXXVI. *Of the Wounds of the Thighes and Legs.*

Wounds which have been received on the inside of the Thighes, have often caused sodain death, if they have come to the vein *Saphena*, or the great Artery, or the Nerves, the associates of these vessels. But when they are simple, there is nothing which may alter the usuall manner of cure. Yet the Patient must be carefull to lye in his bed: for the vulgar *Italian* proverb is true: *La mano al petto, la gamba al letto*, [that is, the hand on the breast, and the leg on the bed.] But when they penetrate more deeply into the substance of the part, they bring horrid and fearfull symptomes, as an inflammation, an abscess, from whence oft-times such abundance of matter issues forth, that the Patient falls into an *Atrophia* and consumption. Wherefore such wounds and ulcers require a carefull & industrious Chirurgeon, who may fitly make incisions necessary for the corrupt parts, & callosity of the fistulous ulcer. Some Chirurgeons have been so bold as to sow together the end of the Tendons of the Ham, and of other joints, when they have been quite cut asunder. But I durst never attempt it for fear of pain, convulsions and the like horrid Symptomes. For the wounds of that large tendon which is composed in the calf of the Leg by the concurrence of three muscles, and goes to the heel, I have observed that when it hath been cut with the sword, that the wounds have been long and hard to cure; and besides when at the last they have been healed, as soon as the Patient hath got out of his bed, and indeavoured to go, they have grown ill and broke open again. Wherefore in such like wounds let the Patient have a care that he begin not to go or too boldly to use his hurt leg before it be perfectly cicatrized and the scar grown hard. Therefore that the Patient may be in more safety, I judg it altogether necessary, that he use to go with Crutches, for a good while after the wound is perfectly healed up.

Why
wounds of
the inside

are oft-
times dead-
ly.

The large
Tendon of
the heel
hard to
consolidate.

CHAP. XXXVII. *Of the Wounds of the Nerves and nervous parts.*

The continuity of the nervous parts is divers wayes loosed by the violent incursion of external things; as by things which contuse, batter and grind in sunder, as by the blow of a stone, cudgell, hamnier, lance, bullet out of a gun, or crossbow; by the biting of greater teeth; or the pricking of some sharpe thing, as a needle, bodkin, penknife, arrow, splinter; or the puncture of some venomous thing, as of a Sea Dragon; or the edge of some cutting thing, as a sword or rapier; or of stretching things which violently tear asunder the nervous bodies. Hence therefore it is, that of such wounds some are simple, others compound, and the compound, some more compound than other. For of these some are superficially and short, others deep and long, some run alongst the nervous body, others run broadwayes; some cut the part quite asunder, others only a portion thereof. The symptomes which follow upon such wounds are, vehement pain, and defluxion, inflammation, abscess, fever, delirij

Differences
drawn from
things
wounded.

Their
Symptomes.

Why a puncture of a nerve is deadly.

um, sowning, convulsion, gangrene, sphacell; whence often death insues by reason of that sympathy, which all the nervous parts have with the brain. Amongst all the wounds of the nervous parts, there is none more to be feared then a puncture, or prick, nor any which causeth more cruell and dangerous symptomes. For by reason of the straitness of the wound, medicines can neither be put in, nor the sanious matter pass forth; now the sanious matter by long stay acquires virulency, whereby the nervous parts are tainted and swoln, suffer pain, inflammation, convulsions, and infinite other symptomes; of these the wounds are most dangerous, by which the nervous and membranous bodies are but half cut asunder. For the portion thereof which remains whole, by its drawing & contracting it self towards the originall, causeth great pain and convulsion by sympathy. The truth hereof is evident in wounds of the head, as when the *pericranium* is half cut, or when it is cut to apply a trepan. For the cutting thereof infers far greater pain, than when it is cut quite asunder. Wherefore it is safer to have the nervous body quite cut off, for so it hath no community, nor consent with the upper parts, neither doth it labour, or strive to resist the contraction of its self; now this contrariety, and as it were fight, is the cause of pain, yet there arises another misery from such a wound, for the part whereinto the nerve which is thus cut insunder passes, thence forwards loseth its action.

CHAP. XXXVIII. Of the cure of Wounds of the Nervous parts.

A wound of the nervous parts indicates contrary to the general cure of wounds. A History.

Tis the ancient doctrine of the ancient Physicians, that the wounds of the nervous parts should not presently be agglutinated (which notwithstanding the generall and first indication usually taken from the solution of continuity requires) but rather, chiefly if they be too strait, that the punctures should be dilated, by cutting the parts which are above them, and let them be kept long open that the filth may pass freely forth, and the medicine enter well in. Yet I in many cures have not followed this counsel, but rather that which the common indication requires.

Medicines fit for wounds of the nerves.

That cure is in fresh memory which I performed upon *Monsieur le Cocq*, a Proctor of the spirituall court, who dwelt in our Ladies street; he gathering and binding up some loose papers, run a penknife which was hid amongst them, through his hand. Also one of his neighbours who went to spit a piece of beef, thrust the spit through the midst of his hand; But I presently agglutinated both their wounds, without any danger, dropping presently in at the first dressing a little of my balsam warm, and putting about it a repelling and astringent medicine, and by this means they were both of them healed in a short time, no symptome thereupon happening. Yet I would not have the young Chirurgeon to run this hazard, for first he must be well practised and accustomed to know the tempers and habits of men; for this manner of curing would not do well in a plethorick body, or in a body replete with ill humors, or indued with exquisite sense. Therefore in such a case it will be safer to follow the course here set down. For wounds of the nerves do not only differ from other wounds, but also among themselves in manner of curing. For although all medicines which draw from far, and waste sanious humors, may be reputed good for the wounds of the nerves; yet those which must be applied to punctures and to those nerves which are not wholly laid open, ought to be far more powerful, sharp & drying, yet so that they be not without biting, that so penetrating more deep they may draw forth the matter, or else consume and discuss that which either lies about the nerves, or moistens their substance. On the contrary, when the sinews are bared from flesh and adjoining particles, they stand in need but of medicines, which may only dry. Here you may furnish your selves with sufficient store of medicines good for the nerves howsoever pricked. As *R. Terebinth. venet. & olei veteris an. ʒ j. aquæ vitæ parum.* Or *R. olei Terebinth. ʒ j. aquæ vitæ ʒ j. euphor. ʒ β.* Or *R. radices Dracontia, Brionia, valeriana, & gentiana exsiccatas, & in pulverem redactas, misce cum decocto centaurii, aut olco, aut exungia veteri;* drop hereof warm into the wound as much as shall suffice. Or else put some Hogs, Goose, Capons, or Bears greafe, old oil, oil of Lillies or the like, to *Galbanum*, pure *Rozin*, *opopanax* dissolved in *aqua vitæ* and strong vinegar. Or *R. olei hypericonis sambati, & de euphorbio an. ʒ j. sulphuris vivi subtiliter pulverisati ʒ β, gummi ammoni. bdellii an. ʒ ij. acetii boni ʒ ij. vermium terrest. preparat. ʒ j. bulliant omnia simul ad consumptionem acetii.* Let as much hereof as shall suffice be dropped into the wound; then apply this following cerate, which draws very powerfully. *R. olei supra scripti ʒ j. terebinth. venet. ʒ β. diachylonis albi cum gummi, ʒ x. ammoniac. bdellii in aceto dissolutorum, an. ʒ ij. resin. pini, gum. elemi, picis navalis an. ʒ v. cere quod sufficit, fiat ceratum satis molle.* We must use some whiles one, some whiles another of these medicines in punctures of the Nerves with choise and judgment, according to their conditions, manner, depth, and the temperaments and habit of the wounded bodies. But if the pain yeeld not to such remedies, but rather increase, with the inflammation of the affected part, a swelling of the lips of the wound, and sweating forth of a serous, thin and virulent matter or filth, then you shall poure into it scalding oil, and shall touch three or four times not only the surface of the wound but the bottom thereof with a rag dipped therein and tyed to the end of a *spatula*. For this will take away the sense from the Nerve, Tendon, or Membrane, like as if they were burnt with a cautery, and so the pain will be eased. So in the most grievous pains of rotten teeth, the thrusting of an hot iron into their roots, or stopping them with cotten dipped in oyl of *Vitrioll*, or *aqua vitæ*, gives most certain ease; for by burning the nerve which is inserted into their roots, the sense and so consequently the pain is taken away. So also in malignant, gnawing, eating, and spreading ulcers, which are alwayes associated with much pain, the pain ceases by applying an *Escharotick*, as the powder of Alum, or Mercury, or *gyptiacum* made somewhat more strong than usual. That the young Chirurgeon may be more ready for this practise and the use of the former medicines, I have thought good to insert the following History both for the lateness of the thing and the pleasing memory of the most laudable Prince.

What wounds of the Nerves must be burnt.

A certain Anodyne in pain of the teeth.

Why Escharoticks must be used to spreading ulcers. A famous history.

Charles the ninth, the French King, being sick of a Fever, *Monsieur Gouellan* and *Castellan* his Physicians thought it fit he should be let blood; for the performance whereof, there was called a Chirurgeon wondrous famous for that business; but when as he by chance had pricked a nerve in stead of a vein, the

King cryed out, that he felt a mighty pain in that place. Then I bid, that the ligature should straightwaies be loosed, otherwise the arm would presently be much swelled. But he going slowly about it, beheld the arm began to swel with such contraction, that he could not bend it, nor put it forth, and cruel pain molested not only the pricked particle, but all the whole member besides. I forthwith laid upon the wound a plaister of *Basilicon*, to hinder the agglutination thereof, & then I wrapped al the arm in a double linnen cloth dipped in oxycrate, putting upon it an expulsive ligature, which beginning at the wrist and ending at the top of the shoulder, might keep the blood and spirits from fear of defluxion and inflammation. This being thus performed, we went aside to consult what was necessary to be done, both to assuage the pain, as also to divert the other symptoms, which usuallly happen upon punctures of the nerves. I being desired, thus delivered my opinion, that in my mind, there were nothing better, then presently to drop into the wound some oyl of Turpentine warmed and mixed with a little *aqua vite*. And then all the arm should be covered with a plaister of *Diacaltheos* dissolved in vinegar and oyl of Roses, bound over and besides with the expulsive ligature, which we formerly mentioned. For the oyl and *aqua vite* have a faculty to penetrate into the bottome of the wound, and to exhaust and dry up the ferous and virulent humor, which sweats from the substance of the pricked nerve; and also to mitigate the pain by its actuall heat. Furthermore the emplaister *Diacaltheos* hath a faculty to dissolve the humor which hath already fallen down into the arm, and to hinder the entrance and defluxion of any new matter. And the ligature is such as by its moderate astringion would serve to strengthen the muscles, and to press out and repell the humors which were fallen down into the upper part, and to prohibit that which is ready to fall down. Mine advice being approved of the Physitians both in word and deed, the pain was mitigated. But the humor stayed in the part, for the dissolving and drying whereof, this following remedy was used. *R. far. hordei & orobi an. ʒ ij. flor. cham. em. & melilot. an. p. ij.* *Butyr. recentis sine sale ʒ i ʒ. lixivii barbitonforis quod sufficit, fiat cataplasma ad formam pultis.* By these remedies and drying cataplasms. the King at the last after 3. months space was perfectly healed, so that there remained no sign of the depraved action in the part. But if at any time there shall be so great contumacy, that it will not yeeld to these means, but that there is imminent danger of a convulsion; it will be better to cut it in sunder whether Nerve, Tendon or Membrane, than to expose the Patient to the danger of a deadly convulsion; for thus indeed the peculiar action of that part will be lost, but the whole body preserved thereby; for so we had determined by common consent, that if the pain which afflicted the King would not yeeld to the prescribed remedies, either to poure in scalding oyl, or else to cut the sinew quite asunder.

For the late and sad memory of Mistris *Courtin* dwelling in the street of the holy-Cross was in our minds, who of a vein not well opened in her arm fell into a Gangrene and totall mortification of that whole part, of which she dyed, because she was not dressed with the formerly mentioned medicins. Yet we must abstain from these too powerfull remedies, when the pricked nerve shall lye bare, for else the pain would be increased, & more grievous symptoms follow. Wherefore as I formerly wished; more mild medicins must be applyed, which may dry up the ferous humor without biting or acrimony, as *R. terebinth. venet. in aq. ros. lot. ʒ ij. boli armeni subtiliter pulverisati, ʒ ij. incorporentur simul.* Our Balsam also is excellent in this case, and this of *Vigoes* wech follows. *R. olei rosar. omphacini ʒ j ʒ. olei de terebinth. ʒ iij. succi plantag. ʒ ʒ. semin. hypericonis aliquantum contriti, m. ʒ. tutie prepar. ʒ iij. calcis decies lot. cum aqua plantagin. ʒ ij. antimonii ʒ j. sevi hircini, & vitulini, an. ʒ v. vermium terrestrium cum vino lotorum ʒ j ʒ. bulliant omnia simul dempta tutia in cyatho decoctionis hordei, ad consumptionem aquae & vini, coentur, rursusq; igni admoveantur, addendo tutiam, & fiat linimentum cum cera alba, & ʒ ʒ. croci.* This liniment asswages pains, & covers the bared nerves with flesh. This cure of punctured nerves, may with choise and judgment and observing the proportion of the parts be transferred to the pricked Tendons and membranes. But take this as a generall & common rule, that all nervous bodies howsoever hurt, are to be comforted by anointing them with hot oyls, such as the oyls of Bayes, Lillies, of Worms, Sage, or some other such like remedy being applyed to their originalls and more notable passages; as to the originall of the spinall marrow, the armpits and groins. Neither do I think it fit in this place to omit an affect which sometimes happens to the large Tendon of the heel, of which we formerly made mention. For it oft-times is rent or torn by a small occasion without any sign of injury or solution of continuity apparent on the outside as by a little jump, the slipping aside of the foot, the too nimble getting on horseback, or the slipping of the foot out of the stirrop in mounting into the saddle. When this chance happens it will give a crack like a Coachmans whip; above the heel, where the tendon is broken, the depressed cavity may be felt with your finger, there is great pain in the part, and the party is not able to go. This mischance may be amended by long lying and resting in bed, and repelling medicins applyed to the part affected in the beginning of the disease, for fear of more grievous symptoms, and then applying the Black plaister, or *Diacaltheos* or some other such, as need shall require; neither must we hereupon promise to our selves or the Patient certain or absolute health. But on the contrary at the beginning of the disease we must foretell that it will never be so cured but that some reliques may remain, as the depression of the part affected and depravation of the action and going; for the ends of this broken or relaxed Tendon by reason of its thickness and contumacy cannot easly be adjoined, nor being adjoined, united.

CHAP. XXXIX. *Of the wounds of the joynts.*

BEcause the wounds of the joynts have something proper and peculiar to themselves, besides the common nature of wounds of the Nerves, therefore I intend to treat of them in particular. Indeed they are alwayes very dangerous, and for the most part deadly by reason of the nervous productions and membranous Tendons wherewith they are bound and ingirt and into which the Nerves are inserted: whereby it comes to pass, that the exquisite sense of such like parts will easly bring malign symptoms, especially if the wound possess an internall, or as they term it, a domestique part of them; as for example, the armpits, the bending of the arm, the inner part of the

wrist, and ham, by reason of the notable Veins, Arteries, and Nerves of these parts, the loosed continuity of all which brings a great flux of blood, sharpe pain and other malignant symptoms; all which we must resist according to their nature and condition, as a flux of blood with things staying, bleeding; pain with anodynes. If the wound be large and wide, the severed parts shall be joined with a suture, leaving an orifice in the lower part, by which the quittance may pass forth. This following powder of *Vigoes* description must be strewed upon the future. *R. thuris sang. draconis, boli armen. terræ sigill. an. ʒ ij. aloes, mastich. an. ʒ j. fiat pulvis subtilis.* And then the joynt must be wrapped about with a repercussive medicine composed of the whites of Eggs, a little oil of Roses, Bole, Mastich, and barley flowre. If it be needfull to use a Tent, let it be short, and according to the wound thick, lest it cause pain: and moreover let it be anointed with the yolk of an egg, oil of Roses, washed turpentine and a little saffron. But if the wound be more short & narrow, it shall be dilated, if there be occasion, that so the humor may pass away more freely. You must rest the part, and beware of using cold, relaxing, mollifying, humecting, and unctuous medicines, unless peradventure the sharpness of the pain must be mitigated. For on the contrary, astringent and desiccant medicins are good, as this following cataplasm. *R. surfur. macri, farin. hordei, & fabarum. an. ʒ iiij. florum chamæ. & melil. an. m. ʒ. terebinth. ʒ iiij. mellis communis ʒ ij. ol. myrtin. ʒ j. oxymelitis, vel oxycrat. vel lixivii com. quantum sufficit, fiat cataplasma ad formam pultis.* Or you may compose one of the lees of wine, Wheat bran, the powder of Oaken bark, cypres nuts, galls and Turpentine, and such like, that have an astringent, strengthening and drying quality, and thereby asswaging pain, and hindering the defluxion of humors. This following medicine is astringent and agglutinative. *R. terebinth. venet. ʒ ij. aq. vitæ parum. pulveris mastich. aloes, myrrhæ, boli armen. an. ʒ ij.* And also our balsam will be good in this case, if so be that you add hereto so much powder which dries without acrimony, as occasion shall serve. I admonished you before to take heed of cold, and now again; for it is hurtfull to all wounds and ulcers, but especially to these of the nervous parts; hence it is that many dye of smal wounds in the winter, who might recover of the same wounds though greater in the Summer. For cold according to *Hippocrates* is nipping to ulcers, hardens the skin, and hinders them from suppuration, extinguisheth naturall heat, causes blackness, cold aguish fits, convulsions, and distentions. Now divers excrements are cast forth of wounds of the joynts, but chiefly albugineous, that is, resembling the white of an egg, and mucous, and sometimes a very thin water, all which favour of the nature of that humor which nourisheth these parts. For to every part there is appropriate for his nourishment and conservation, a peculiar balsam, which by the wound flows out of the same part, as out of the branches of the vine, when they are pruned, their radical moisture or juyce flows; whence also a *Callus* proceeds in broken bones. Now this same mucous, & albugineous humor, slow & as it were frozen flowing from the wounded joynts, shews the cold distemper of the parts, which cause pain, not to be overcome by medicins only potentially hot. Wherefore to correct that, we must apply things actually hot, as beasts and swines bladder half full of a discussing decoction, or hot bricks quenched in wines. Such actual heat helps nature to concoct and discuss the superfluous humor impact in the joynts, and strengthens them; both which are very necessary, because the naturall heat of the joynts is so infirm that it can scarce actuate the medicin unless it be helped with medicins actually hot. Neither must the Chirurgeon have the least care of the figure and posture of the part, for a vicious posture increases ill symptoms, uses to bring to the very part though the wound be cured, distortion, numbness, incurable contraction; which fault lest he should run into, let him observe what I shall now say; If the forepart of the shoulder be wounded, a great boulster must be under the armpit, and you must carry your arm in a scarf, so that it may bear up the lower part of the arm, that so the top of the shoulder may be elevated somewhat higher, and that so it may be thereby more speedily and happily agglutinated and consolidated. If the lower part be wounded, when flesh begins to be generated and the lips of the wound to meet, you must bid the Patient to move and stir his arms divers wayes ever & anon, for if that be omitted or negligently done, when it is cicatrized, then it will be more stiffe and less pliable to every motion; and yet there is a further danger lest the arm should totally lose its motien. If the wound be upon the joynt of the elbow, the arm shall be placed and swathed in a middle posture, that is, which neither too straitly bows it, nor holds it too stiffe out; for otherwise when it is cicatrized, there will be an impediment either in the contraction or extention. When the wound is in the wrist, or joints of the fingers either externally or internally, the hand must be kept half shut, continually moving a ball therein. For if the fingers be held straight stretched forth, after it is cicatrized, they will be unapt to take up or hold any thing, which is their proper faculty. But if after it is healed, it remain half shut, no great inconveniency will follow thereon; for so he may use his hand divers wayes to his sword, pike, bridle and in any thing else. If the joints of the Hip be wounded, you must so place the Patient that the thigh bone may be kept in the cavity of the hucklebone, and may not part a hairs breadth there from, which shall be done with linnen bouldsters and ligatures applyed as is fitting, and lying full upon his back. When the wound shall begin to cicatrize, the Patient shall use to move his thigh every way, lest the head of the thigh-bone stick in the cavity of the hucklebone without motion. In a wound of the knee, the leg must be placed straight out, if the Patient desire not to be lame. When the joints of the feet and toes are wounded, these parts shall neither be bended in nor out, for otherwise he will not be able to go. To conclude, the site of the foot and leg, is quite contrary to that of the arm and hand.

CHAP. XL. Of the wounds of the Ligaments.

The wounds of the Ligaments, besides the common manner of curing these of the Nerves, have nothing peculiar, but that they require more powerfull medicins, for their agglutination, desiccation and consolidating; both because the Ligamentall parts are harder, and drier, and also for that they are void of sense. Therefore the foresaid cure of Nerves, and joints may be used for these wounds: for the Medicins in both are of the same kind, but here they ought to be stronger

The cure.

An astringent and drying cataplasm.

Aphor. 20. sect. 5.

V What matter usually flows from wounds of the joynts.

V Why things actually hot must be applyed to the wounded joynts. Of the site and posture of wounded joints.

Ligaments more dry than Nerves, and without sense.

stronger and more powerfully drying. The Theory and cure of all the symptoms which shall happen thereupon have been expressed in the Chapter of curing the wounds of the nervous parts, so that here we shall need to speak nothing of them, for there you may find as much as you will. Wherefore here let us make an end of wounds, and give thanks to God the author and giver of all good for the happy proesse of our labours, and let us pray that that which remains may be brought to a happy end, and secure for the health and safety of good people.

The end of the tenth Booke.

Of Wounds made by Gunshot, other fiery Engines, and all sorts of Weapons.

THE ELEVENTH BOOK.

The Preface.

Have thought good here to premise my opinion of the originall, encrease, and hurt of fiery Engines, for that I hope it will be an ornament and grace to this my whole treatise: as also to intice my Reader, as it were with these junckets, to our following Banquet so much favouring of Gunpowder. For thus it shall be known to all whence Guns had their originall and how many habits and shapes they have acquired from poore and obscure beginnings; & lastly how hurtfull to mankind the use of them is.

Polydore Virgill writes that a Germane of obscure birth and condition was the inventor of this new engin which we term a Gun, being induced thereto by this occasion. He kept in a mortar covered with a tyle, or slate, for some other certain uses a powder (which since that time for its chief and new known faculty, is named Gunpowder.) Now it chanced as he struck fire with a steel and flint, a spark thereof, by accident fell into the mortar, whereupon the powder suddainly catching fire, casts the stone or tyle which covered the mortar, up on high; he stood amazed at the novelty & strange effect of the thing, and withall observed the formerly unknown faculty of the powder; so that he thought good to make experiment thereof in a small Iron trunk framed for that purpose according to the intention of his mind. When all things were correspondent to his expectation, he first shewed the use of his engine to the Venetians, when they warred with the Genoveses about *Fossa Clodia*, in the year of our Lord 1380. Yet in the opinion of *Peter Messius*, their invention must have been of greater antiquity; for it is read in the Chronicles of *Alphonfus* the eleaventh King of *Castile*, who subdued the *Isles Argezires*, that when he besieged the chiefe Town in the year of our Lord 1343. The besieged Moores shot as it were thunder against the assailants, out of Iron mortars. But we have read in the Chronicles written by *Peter Bishop* of *Leons* of that *Alphonfus* who conquered *Toledo*, that in a certain sea fight fought by the King of *Tunis*, against the Moorish King of *Sivill*, whose part King *Alphonfus* favoured, the *Tunetans* cast lightning out of certain hollow Engines or Trunks with much noise. Which could be no other, than our Guns, though not attained to that perfection of art and execution which they now have.

I think the deviser of this deadly Engin hath this for his recompence, that his name should be hidden by the darknes of perpetuall ignorance, as not meriting for this his most pernicious invention, any mention from posterity. Yet *Andrew Thevet* in his *Cosmography* published some few years ago, when he comes to treat of the *Suevi*, the inhabitants of Germany, brings upon the authority and credit of a certain old Manuscript, that the Germane the inventor of this warlike Engine was by profession a Monk and Philosopher or Alchymist, born at *Friburg*, and named *Constantine Anclzen*. Howsoever it was, this kind of Engine was called *Bombarda* (i) a Gun, from that noise it makes, which the Greeks and Latines according to the sound call *Bombus*; then in the following ages, time, art and mans malicioufness added much to this rude and unpolisht invention. For first for the matter, Brasse and Copper, metalls farre more tractable, fusible and lesse subject to rust, came as supplies to Iron. Then for the form, that rude and undigested barrell, or mortar-like masse, hath undergone many formes and fashions, even so far as it is gotten upon wheels, that so it might run not only from the higher ground, but also with more rapid violence to the ruin of mankind; when as the first and rude mortars seemed not to be so nimble traversed, nor sufficiently cruell for our destruction by the only casting forth of Iron and fire. Hence sprung these horrible monsters of Canons, double Canons, Bastards, Musquits, Field peeces; hence these cruell and furious beasts, Culverins, Serpentes, Basilisques, Sackers, Falcons, Falconets, and divers other names not only drawn from their figure and making, but also from the effects of their cruelty. Wherefore certainly I cannot sufficiently admire the wisdom of our Ancestors, who have so rightly accommodated them with names agreeable to their natures; as those who have not only taken them from the swiftest birds of prey, as Falcons; but also from things most harmfull and hatefull to mankind, such as Serpents, Snakes, and Basilisques. That so we might clearly discern, that these engines were made for no other purpose, nor with other intent, but only to be employed for the speedy and cruell slaughter of men; and that by only hearing them named we might detest and abhor them, as pernicious enemies of our lives. I let passe other engines of this offspring, being for their quantity small, but so much the more pernicious & harmfull, for that they nearer assail our lives, may traiterously and forthwith seize upon us not thinking nor fearing any such thing; so that we can scarce have

Lib. 2. de invent. rerum.

Cap. 8. prim. par. var. lect.

VVho the inventor of Guns.

The reason of the name.

The danger of Pistols. have any means of escape; such are Pistols and other small hand-guns, which for shortness you may carry in your pocket, and so privily and suddainly taking them forth oppress the careless and secure. Fowling peeces which men usually carry upon their shoulders, are of the middle rank of these engines, as also Muskets, and Calcevers, which you cannot well discharge unless lying upon a Rest, which therefore may be called Breast-guns for that they are not laid to the cheek, but against the Breast by reason of their weight and shortness; All which have been invented for the commodity of footmen, and light horsemen. This middle sort of engine we call in Latine by a generall name *Sclopius*, in imitation of the sound, and the Italians who term it *Sclopetere*; the French call it *Harquebuse*, a word likewise borrowed from the Italians, by reason of the the touch-hole by which you give fire to the peece, for the Italians call a hole *Buzio*. It is tearmed *Arcus* (i) a Bow, for that at this present it holds the same place in martiall affaires, as the Bow did of old; and as the Archers formerly, so at this day the Musquetiers are placed in front. From the same wretched shop and magazine of cruelty, are all sorts of Mines, Countermine, pots of fire, trains, fiery Arrows, Lances, Crossbowes, barrells, balls of fire, burning faggots, Granats, and all such fiery engines and Inventions, which closely stuffed with suell and matter for fire, and cast by the defendants upon the bodies and Tents of the assailants, easily take fire by the violence of their motion. Certainly a most miserable and pernicious kind of invention, whereby we often see a thousand of heedlesse men blown up with a mine by the force of Gunpowder; otherwhiles in the very heat of the conflict you may see the stoutest souldiers seised upon with some of these fiery Engines, to burn in their harness, no waters being sufficiently powerfull to restrain and quench the raging and wasting violence of such fire cruelly spreading over the body and bowells. So it was not sufficient to have armes, Iron and fire to mans destruction, unlesse also that the stroak might be more speedy, we had furnished them, as it were with wings, so to fly more hastily to our own perdition, furnishing sith-bearing death with wings so more speedily to oppress man, for whose preservation, all things contained in the world were created by God. Verily when I consider with my self all the sorts of warlike Engines, which the ancient used, whether in the field in set battlls, as Bowes, Darts, Crossbowes, Slings; or in the assault of Cities, & shaking or overturning their walls, as Rams, Horses, wooden towres, slings and such like; they seem to me certain childish sports & games made only in imitation of the former. For these moderna inventions are such as easily exceed all the best appointed and cruell Engines which can be mentioned or thought upon, in the shape, cruelty and appearance of their operations. For what in the world is thought more horrid or fearfull than thunder and lightning? and yet the hurtfulness of thunder is almost nothing to the cruelty of these infernall Engines; which may easily appear by comparing together both their effects. Man alone of all creatures is not alwayes killed by being touched with thunder; but it immediatly killeth all other things which are subject to be toucht therewith. Nature bestowing this honour upon him, seeing so many creatures exceed him in strength: For all things ly contrary to man; and man, unless he be overthrown with it, doth not dye thereof. But these fire-spitting Engines do no more spare man, then they do other creatures, and kill without difference from whence soever they come, whither soever they are carryed, and howsoever they touch. There are many, but more are said to be the remedies against thunder; for beside the charms whereby the ancient Romans did suppose they might be driven away, they never penetrate deeper into the ground than five foot, therefore such as was fearfull thought the deeper caves most safe. Of those things which grow out of the earth, they do not touch the Bay tree, and that was the cause that it was counted a sign of Victory both in ancient and moderne times. Wherefore *Tiberius Caesar* otherwise a contemner of God and religion, as he who indued with the Mathematicall sciences thought all things governed by Fate, yet because he exceedingly feared thunder, he alwayes carried a Lawrell wreath about his neck when the aire was troubled, for that this kind of leaf is reported not to be touched by thunder. Some report that he made him tents of Seales skinnes, because it toucheth not this kinde of creature of all these things that live in the Sea, as neither the Eagle amongst birds, which for that is fained to be *Joves* squire. But on the contrary, charms, the victorious Bay, the Seale or Sea-calf, the Eagle or any such thing profits nothing against the violence of these fiery engines: no not a wall of ten foot thick will advantage. Lastly, this argues the immense violence of brasen Cannons above thunder, for that thunder may be dispersed and driven away with the noise and ringing of Bells, the founding of Trumpets, the tinkling of brasen kettles, yea also by the shooting of such great Ordnance; to wit, the clouds, by whose collision and fight the Thunder is caused, being dispersed by this violent agatation of the air, or else driven further to more remote parts of the skies. But their fury once provoked, is stayed by no opposition, appeased by no remedy. As there are certain seasons of the year, so also there are certain Regions of the earth, wherein Thunder is seldome or never heard. Thunders are rare in Winter and Summer, and that for contrary causes; for that in Winter the dense air is thickned with a thicker coat of clouds, and the frosty and cold exhalation of the earth extinguisheth what fiery vapours so ever it receives; which thing keeps *Scythia* and the cold countries about it free from Thunder. And on the contrary, too much heat preserves *Egypt*. For hot and dry exhalations of the earth are condensed into very thin, subtil and weak clouds. But as the invention, so also the harm and tempest of great Ordnance, like a contagious pestilence is spread and rages over all the earth, and the skies at all times sound again with their reports. The Thunder and Lightning commonly gives but one blow, or stroke, and that commonly strikes but one man of a multitude; But one great Cannon at one shot may spoil and kill a hundred men. Thunder, as a thing naturall, falls by chance, one while upon a high oak, another while upon the top of a mountain, and somewhiles on some lofty towre, but seldom upon man. But this hellish Engine tempered by the malice and guidance of man, assailes man only, and takes him for his only mark, and directs his bullets against him. The Thunder by its noise as a messenger sent before, foretells the storm at hand; but, which is the chief mischief, this infernall Engine

juice therein: then he strained it through a towell without much pressing; and added the Turpentine roars as it strikes, and strikes as it roars, sending at one and the same time the deadly bullet into the breast, and the horrible noise into the ear. Wherefore we all of us rightfully curse the author of so pernicious an Engine; on the contrary praise those to the skies, who endeavour by words and pious exhortations to dehort Kings from their use, or else labour by writing and operation to apply fit medicines to wounds made by these Engines. Which hath moved me, that I have written hereof almost with the first of the French. But before I shall do this, it seemeth not amisse, so to facilitate the way to the treatise I intend to write of wounds made by Gunshot, to premise two Discourses, by which I may confute and take away certain erroneous opinions which have possessed the mindes of divers; for that unless these be taken away, the essence and nature of the whole disease cannot be understood, nor a fitting remedy applied by him which is ignorant of the disease.

The first Discourse which is dedicated to the Reader, refells and condemnes by reasons and examples the method of curing prescribed by *Iohn de Vigo*, whereby he cauterizeth the wounds made by Gunshot, supposing them venenate; and on the contrary proves that order of curing which is performed by suppurations, to be so salutary and gentle, as that prescribed by *Vigo* is full of error and cruelty. The second dedicated to the King, teaches that the same wounds are of themselves void of all poison, and therefore that all their malignity depends upon the fault of the air, and ill humors predominant in the bodies of the patients.

The arguments of the following discourses.

The first discourse wherein Wounds made by Gunshot, are freed from being burnt, or cauterized according to Vigos Method.

IN the year of our Lord 1536. *Francis* the French King, for his acts in war and peace stiled the Great, sent a puissant Army beyond the Alpes, under the government and leading of *Annas* of Mommorancy high Constable of France, both that he might relieve *Turin* with Victualls, souldiers, and all things needfull, as also to recover the Cities of that Province taken by the Marquis of *Guaft* Generall of the Emperours forces. I was in the Kings Army the Chirurgeon of Monsieur of *Montejan* Generall of the foot. The Imperialists had taken the straits of *Suze*, the Castle of *Villane*, and all the other passages; so that the Kings army was not able to drive them from their fortifications but by fight. In this conflict there were many wounded on both sides with all sorts of weapons, but chiefly with bullets. I will tell the truth, I was not very expert at that time in matters of Chirurgery; neither was I used to dress wounds made by Gunshot. Now I had read in *Iohn de Vigo* that wounds made by Gunshot were venenate or poisoned, and that by reason of the Gunpowder; Wherefore for their cure, it was expedient to burn or cauterize them with oil of Elders scalding hot, with a little Treacle mixed therewith. But for that I gave no great credit neither to the author, nor remedy, because I knew that causticks could not be powred into wounds, without excessive pain; I, before I would run a hazard, determined to see whether the Chirurgeons, who went with me in the army, used any other manner of dressing to these wounds. I observed and saw that all of them used that Method of dressing which *Vigo* prescribes; and that they filled as full as they could, the wounds made by Gunshot with Tents and pledgets dipped in this scalding Oil, at the first dressings; which encouraged me to do the like to those, who came to be dressed of me. It chanced on a time, that by reason of the multitude that were hurt, I wanted this Oil. Now because there were some few left to be dressed, I was forced, that I might seem to want nothing, and that I might not leave them undrest, to apply a digestive made of the yolk of an egge, oil of Roses, and Turpentine. I could not sleep all that night, for I was troubled in mind, and the dressing of the precedent day, (which I judged unfit) troubled my thoughts; and I feared that the next day I should find them dead, or at the point of death by the poison of the wound, whom I had not dressed with the scalding oil. Therefore I rose early in the morning, I visited my Patients, and beyond expectation, I found such as I had dressed with a digestive only, free from vehemency of pain to have had good rest, and that their wounds were not inflamed nor runnified; but on the contrary the others that were burnt with the scalding oil were feverish, tormented with much pain, and the parts about their wounds were swolne. When I had many times tryed this in divers others, I thought thus much, that neither I nor any other should ever cauterize any wounded with Gunshot. When we first came to *Turin*, there was there a Chirurgeon far more famous than all the rest in artificially and happily curing wounds made by Gunshot; wherefore I laboured with all diligence for two yeers time to gain his favour and love; that so at the length, I might learn of him, what kind of Medicine that was, which he honoured with the glorious title of Balsam, which was so highly esteemed by him, and so happy and succesfull to his patients; yet could I not obtain it. It fell out a small while after that the Marshall of *Montejan* the Kings Lieftenant, Generall there in *Piemont* dyed, wherefore I went unto my Chirurgeon, and told him that I could take no pleasure in living there, the favourer and *Mecenas* of my studies being taken away; and that I intended forthwith to return to *Paris*, and that it would neither hinder, nor discredit him to teach his remedy to me, who should be so far remote from him. When he heard this, he made no delay, but presently wished me to provide two Whelpes, 1 pound of earthwormes, 2 pounds of oil of Lillies, six ounces of Venice Turpentine, and one ounce of *aqua vite*. In my presence he boyled the Whelpes put alive into that oil, untill the flesh came from the bones, then presently he put in the Wormes, which he had first killed in white wine, that they might so be cleansed from the earthy drosse wherewith they are usually repleat, and then he boyled them in the same oil so long, till they became dry, and had spent all their juice

Lib. 1. de vul. nr. Cap. 8.

What chance may do in finding out of remedies.

The description of oil of Whelpes.

to it, and lastly the *aqua vite*. Calling God to witness, that he had no other Balsam, wherewith to cure wounds made with Gunshot, and bring them to suppuration. Thus he sent me away as rewarded with a most precious gift, requesting me to keep it as a great secret, and not to reveal it to any. When I came to *Paris*, I went to visit *Silvius* the Kings professor of Physick, well known by name to all scholars for his great learning; he kept me long that so I might dine with him, and diligently enquires of me, if I had observed any new Method of curing wounds made by Gunshot, and combustions occasioned by Gunpowder. Then I affirmed to him that Gunpowder did not participate any thing of poyson, for that none of these things whereof it is compounded are poysonous; which reason ought to free the whole composition from suspicion of poyson. And that experience confirmed this reason, for I had seen many souldiers, who would drink a great quantity of this powder with Wine, because they were perswaded, that this drink would free them from malign symptomes when they were wounded; yet I give no credit to this perswasion; and lastly, for that many without any harm, strew this powder upon rebellious ulcers. For the Bullets, I affirm, that they cannot conceive such heat, as to become caustick. For if you shoot them out of a Gun against a hard stone, yet you may presently take them up without any harm in your hands, though by striking upon the stone, they should become more hot. For the combustions caused by Gunpowder, I observed no speciall nor peculiar remedy, which might make their cure different from other combustions. To which purpose I related this insuing history.

Gunpowder
nor poyson-
ous.

Bullets shot
out of a
Gun do not
burn.

A History.

A medicine
hindering
blistering in
burns, or
scalds.

A History.

One of the Marshall of *Montejan* his Kitchin boyes, fell by chance into a Caldron of Oil being even almost boyling hot; I being called to dress him, went to the next Apothecaries to fetch refrigerating medicines commonly used in this case: there was present by chance a certain old countrey woman, who hearing that I desired medicins for a burn, perswaded me at the first dressing, that I should lay two raw Onions beaten with a little salt; for so I should hinder the breaking out of blisters or pustules, as she had found by certain and frequent experience. Wherefore I thought good to try the force of her Medicine upon this greasie scullion. I the next day found those places of his body whereto the Onions lay, to be free from blisters, but the other parts which they had not touched, to be all blistered.

It fell out a while after, that a *German* of *Montejan* his guard had his flasque full of Gunpowder set on fire, whereby his hands and face were grievously burnt: I being called, laid the Onions beaten as I formerly told you, to the middle of his face, and to the rest I laid medicins usually applyed to burns. At the second dressing I observed the part dressed with the Onions quite free from blisters & excoriation, the other being troubled with both; wherby I gave credit to the Medicin. Besides also, I lastly told him this, that I had observed, that that was the readiest to draw forth Bullets shot into the body, which sets the Patient in the same posture and site, as he was when he received his hurt. Which things when I had told him, together with many other handled at large in this work, the good old man requested me to publish in print my opinions concerning these things, that so the erroneous and hurtfull opinion of *Vigo* might be taken out of mens minds. To whose earnest intreaty when I had assented, I first of all caused to be drawn and carved many Instruments fit to draw forth Bullets and other strange bodies; then a short while after I first published this work in the year of our Lord 1545. which when I found to be well liked and approved by many, I thought good to set it forth the second time somewhat amended in the year 1552. And the third time augmented in many particulars in the year 1564. For I having followed many Wars, and detained as Chirurgion in besieged Cities, as *Mets* and *Hesdin*, had observed many things under five Kings, whom I served with diligence and content. I had learnt many things from most expert Chirurgions, but more from all learned Physitians, whose familiarity and favour for that purpose I alwayes laboured to acquire with all diligence and honest Arts; that so I might become more learned and skilfull by their familiarity, and discourse, if there was any thing especially in this matter and kind of wounds, which was hid from me, or whereof I was not well assured. Of which number I have known very few, who any thing seen in this kind of operation either by study, or experience in Wars, who have not thought that Wounds made by Gunshot ought to be dressed at the first with suppurative medicins, and not with scalding and Caustick oil. For this I affirm, which then also I testified to this good man, that I have found very many Wounds made in the fleshy parts by Gunshot, as easily cured as other Wounds, which be made by contusing things. But in the parts of the body where the bullet meets with bones and nervous particles, both because it tears and rends into small peeces those things which resist, not only where it touches, but further also, through the violence of the blow, therefore it causeth many and grievous symptomes, which are stubborn and difficult, and oft-times impossible to cure, especially in bodies replete with ill humors, in an ill constitution of the heaven and air, such as is hot, moist and foggy weather, which therefore is subject to putrefaction; & in like manner a freezing and cold season, which uses to mortifie the wounded parts not only of those that are hurt with Bullets, but in like sort with any other weapon; not only in bony and nervous particles, but also in musculous. Whereby you may understand, that the difficulty of curing proceeds not from the venenate quality of the Wounds; nor the combustion made by the Gunpowder, but the foulness of the Patients bodies, and the unseasonableness of the air.

Wounds
made by
Gunshot
must be
dressed with
suppura-
tives.
The causes
of difficult-
ty in this
cure.

A History.

For proof whereof, I will set down, that which I not long ago, observed in a Scottish Noblemian the Earl of *Gordon*, Lord of *Achindon*, whom I cured at the appointment of the Queen-Mother. He was shot through both his thighes with a Pistoll, the bone being not hurt nor touched; and yet the 32. day after the Wound he was perfectly healed, so that he had neither feaver nor any other symptom which came upon the Wound. Whereof there are worthy witnesses, the Archbishop of *Glasco*, the Scottish Embassadour, *Francis Brigart*, and *John Altine* Doctors of Physick, as also *Iames Guillemeau* the Kings Chirurgion, and *Giles Buzet* a Scottish Chirurgion, who all of them wondred that this Gentleman was so soon healed, no acrid medicin being applyed. This I have thought good to recite and set down, that the Readers may understand, that I for 30. years ago had found the way to cure Wounds made by Gunshot, with-

without scalding oil or any other, more acrid medicin; unless by accident the illness of the Patients bodies and of the air caused any malign symptomes, which might require such remedies besides the regular and ordinary way of curing, which shall be more amply treated of in the following discourse.

Another Discourse of these things, which King Charles the Ninth, returning from the expedition and taking of Roven, inquired of me concerning Wounds made by Gunshot.

Or that it pleased your Majesty one day, together with the Queen Mother, the Prince of the Rock upon Ion, and many other Noble men, and Gentlemen, to inquire of me, what was the cause that the far greater part of the Gentlemen and common Souldiers which were wounded with Guns, and other warlike Engins, all remedies used in vain, either dyed, or scarce and that with much difficulty recovered of their hurts, though in appearance they were not very great, and though the Chirurgeons diligently performed all things requisite in their Art: I have made bold to premise this Discourse to that Tractate which I determine to publish concerning wounds made by Gunshot; both to satisfie the desires of the Princes and of many Gentlemen, as also the expectation they have of me, as being the Kings chief Chirurgeon, (which place being given me by Henry the Second, Charles the Ninth, a Son most worthy of such a Father, had confirmed) neither make I any question, but that many who too much insist upon their own judgment, and not thoroughly consider the things themselves, will marvel, and think it far from reason; that I departing from the steps of my ancestors, and dissenting wholly from the formerly received opinions, am far from their Tenents, who lay the cause of the malignity of wounds made by Gunshot, upon the poyson brought into the body by the Gunpowder, or mixed with the bullets whilst they are tempered or cast. Yet for all this, if they will curiously and patiently weigh my reasons, they shall either think as I do, or at least shall judg this my endeavour and pains taken for the publike good, not to be condemned nor contemned. For I shall make it evident by most strong reasons drawn out of the writings of the Ancients both Philosophers and Physitians, and also by certain experiments of my own, and other Chirurgeons, that the malignity and contumacy which we frequently meet withall in curing wounds made by Gunshot, is not to be attributed either to the poyson carryed into the body by the Gunpowder or Bullet, nor to burning imprinted in the wounded part by the Gunpowder. Wherefore to come to our purpose, that opinion must first be confuted, which accuseth wounds made by Gunshot of poyson; and we must teach, that there is neither any venenate substance, nor quality in Gunpowder, neither if there should be any, could it impoyson the bodies of such as are wounded. Which that we may the more easily perform, we must examin the composition of such powder, and make a particular inquiry of each of the simples, whereof this composition consists, what essence they have, what strength and faculties, and lastly, what effects they may produce. For thus by knowing the simples, the whole nature of the composition consisting of them, will be apparently manifest.

The simples which enter the composition of Gunpowder are only three, Charcoals of Sallow or Willow, or of Hemp stalks, Brimstone, and Salt-peter, and sometimes a little *aqua vite*. You shall find each of these, if considered in particular, void of all poyson and venenate quality. For first in the Charcoal you shall observe nothing but dryness, & a certain subtlety of substance, by means whereof it fires so sodainly, even as Tinder. Sulphur or Brimstone is hot and dry, but not in the highest degree, it is of an oily & viscid substance, yet so that it doth not so speedily catch fire as the coal, though it retain it longer being once kindled, neither may it be so speedily extinguished. Salt-peter is such, that many use it for salt, whereby it is evidently apparent that the nature of such simples is absolutely free from all poyson, but chiefly the Brimstone, (which notwithstanding is more suspected than the rest.) For Dioscorides gives Brimstone to be drunk, or supped out of a rear Egg to such as are Asthmatick, troubled with the cough, spit up purulent matter, and are troubled with the yellow Jaundice. But Galen applies it outwardly to such as are bitten by venomous Beasts, to scabs, teaters, & leprosy. For the *aqua vite*, it is of so tenuous a substance that it presently vanisheth into air, and also very many drink it, and it is without any harm used in frictions of the exterior parts of the body. Whence you may gather, that this powder is free from all manner of poyson, seeing these things whereof it consists and is composed, want all suspicion thereof. Therefore the Germane horsemen, when they are wounded with shot, fear not to drink off cheerfully half an ounce of Gunpowder dissolved in Wine; hence perswading themselves freed from such malign symptomes as usually happen upon such wounds; wherein whether they do right or wrong I do not here determine; the same thing many French souldiers forced by no necessity, but only to shew themselves more courageous, also do without any harm; but divers with good success use to strew it upon ulcers, so to dry them. Now to come to these, who think that the venenate quality of wounds made by Gunshot, springs not from the powder, but from the bullet wherewith some poyson hath been commixt or joyned, or which hath been tempered or steeped in some poysonous liquor. This may sufficiently serve for a reply; that the fire is abundantly powerfull to dissipate all the strength of the poyson, if any should be poured upon or added to the Bullet. This much confirms my opinion which every one knows; The Bullets which the Kings Souldiers used to shoot against the Towns in the siege of Roven, were free from all poyson; and yet for all that they of the Town thought that they were all poysoned, when they found the Wounds made by them, to be incurable and deadly. Now

The occasion of writing this discourse.

The argument of this discourse.

Gunpowder is not poysonous.

Of what it is made.

Lib. 5. Cap. 73. Lib. 9. simpl. Cap. 36.

Bullets cannot be poysoned.

on the other side the Townsmen were falsely suspected guilty of the same crime by the Kings Army, when as they perceived all the Chirurgeons labour in curing Wounds made by the Bullets shot from *Roven*, to be frustrated by their contumacy and malign nature, each side judging of the magnitude and malignity of the cause from the unhappy success of the effect in curing. Even as amongst Physicians according to *Hippocrates*, all diseases are termed pestilent, which arising from whatsoever common cause, kill many people; so also Wounds made by Gunshot, may in some respect be called pestilent, for that they are more refractory, and difficult to cure than others, and not because they partake of any poisonous quality, but by default of some common cause, as the ill complexions of the Patients, the infections of the air, & the corruption of meats and drinks. For by these causes wounds acquire an evil nature, and become less yielding to medicines. Now we have by these reasons convinced of error that opinion which held Wounds made by Gunshot for poisonous; let us now come to overthrow that which is held concerning their combustion.

First, it can scarce be understood how bullets which are commonly made of Lead, can attain to such heat, but that they must be melted, and yet they are so far from melting, that being shot out of a Musket they will pierce through an armour and the whole body besides, yet remain whole, or but a little diminished. Besides also, if you shoot them against a stone wall, you may presently take them up in your hand without any harm, and also without any manifest sense of heat; though their heat by the striking upon the stone should be rather increased if they had any. Furthermore, a Bullet shot into a barrell of Gunpowder, would presently set it all on fire, if the bullet should acquire such heat by the shooting, but it is not so. For if at any time the powder be fired by such an accident, we must not imagine that it is done by the bullet bringing fire with it, but by the striking and collision thereof against some Iron, or stone that opposes or meets therewith, whence sparks of fire proceeding as from a flint, the powder is fired in a moment. The like opinion we have of thatched houses, for they are not fired by the bullet which is shot, but rather by some other thing, as linnen rags, brown paper and the like, which rogues and wicked persons fasten to their bullets. There is another thing which more confirms me in this opinion, which is; take a bullet of Wax, and keep it from the fire, for otherwise it would melt, and shoot it against an inch board, and it will go through it; whereby you may understand that Bullets cannot become so hot by shooting, to burn like a cautery. But the Orifices (may some say) of such Wounds are always black. This indeed is true, but it is not from the effect of heat brought thither by the bullet, but the force of the contusion. Now the contusion is exceeding great, both because the bullet is round, and enters the body with incredible violence. Of which those that are wounded will give you sufficient testimony, for there is none of them, which thinks not presently upon the blow, that as it were some post, or thing of the like weight, falls upon the affected member, whence great pain and stupidity possess the part, whereby the native heat and spirits are so much dissipated, that a Gangrene may follow. But for the Eschar which they affirm is made by the blow, and falls away afterwards, they are much mistaken. For certain particles of the membranes and flesh contused and torn by the violence of the bullet beguile them; which presently putrefying are severed from the sound parts by the power of nature and the separating heat, which thing usually happens in all great Contusions. But for all that these so many and weighty reasons may free the Powder from all suspicion of Poison, and the bullet from all thought of burning; yet there are many who insisting upon Philosophicall arguments raise new stirrs. For (say they) the discharging a peice of Ordnance is absolutely like Thunder and Lightning, which the rent and torn clouds cast from the middle region upon the earth; wherefore the Iron bullet which is shot out of the Cannon must needs have a venenate and burning faculty. I am not ignorant that Lightning generated of a gross and viscous exhalation, breaking the cloud wherewith it is incompassed, never falls upon the earth, but brings fire with it, one while more subtile, another while more gross, according to the various condition of the matter whence the exhalation hath arisen. For *Seneca* writes that there are three severall kinds of Lightning differing in burning, condition and plenty. One of them penetrates or rather perforates by the tenuity of the matter of the object which it touches. The other with a violent impetuosity breaks in sunder and dissipates the objects, by reason it hath a more dense, compact & forcible matter, like as Whirlwinds have. The third, for that it consists of a more terrestriall matter, burns what it touches, leaving behind it the impression of the burning. Also I know that Lightning is of a pestilent & stinking nature, occasioned by the grossness and viscidty of the matter whereof it is; which matter taking fire sends forth so lothsome & odious a smell, that the very wild beasts cannot indure it, but leave their Dens, if they chance to be touched with such a lightning. Besides also we have read in the Northern history of *Olaus Magnus*, that in some places after a Lightning, you shall find a whole Plain spread over with Brimstone, which Brimstone notwithstanding is extinguished, unprofitable, and of no efficacy. But grant these things be thus, yet must we not therefore conclude, that the Bullets of the great Ordnance carry poison and fire with them into the wounds. For though there be many things like in Lightning and discharging great Ordnance, yet they have no similitude either in matter or substance, but only in effects, whereby they shake, break in sunder and disperse the bodies which withstand them; For lightning and thunder do it by means of fire, & oft-times of a stone generated in them, which is therefore termed, a thunderbolt; but Ordnance by the Bullet carried by the force of the air, more violently driving and forcing it forwards. Neither if any should by more powerful arguments force me to yield that the matter of the lightning and shooting of Ordnance are alike, yet will I not therefore be forced to confess that Wounds made by Gunshot are combust. For according to *Pliny*, there are some lightnings which consisting of a most dry matter, do shatter in sunder all that withstands them, but do not burn at all; others which are of somewhat a more humid nature, burn no more than the former, but only black such things as they touch; Lastly, other some of a more subtile and tenuous matter, whose nature (as *Seneca* saith) we must not doubt to be divine, if but for this reason, that they will melt gold & silver, not harming the purse; a sword, not hurt-

ing

ing the purse; a sword, not hurting the scabbard; the head of a Lance, not burning the wood, and shed wine not breaking the vessel. According to which decree I can grant, that these Lightnings which break in sunder, melt and dissipate, and performe other effects so full of admiration, are like in substance to the shot of great Ordnance; but not these which carry with them fire and flame.

In prooffe whereof there comes into my mind the history of a certain Souldier, out of whose thigh I remember I drew forth a Bullet wrapped in the taffety of his breeches, which had not any sign of tearing or burning. Besides, I have seen many who not wounded, nor so much as touched, yet notwithstanding have with the very report and wind of a Cannon bullet, sliding close by their ears, fallen down for dead, so that their members becoming livid and black, they have dyed by a Gangrene ensuing thereupon. These and such effects are like the effects of Lightnings which we lately mentioned, and yet they bear no sign nor mark of poison. From whence I dare now boldly conclude, that Wounds made by Gunshot are neither poisoned, nor burnt. But seeing the danger of such Wounds in these last civil wars hath been so great, universall and deadly to so many worthy personages and valiant men, what then may have been the cause thereof, if it were neither combustion, nor the venenate quality of the Wound? This must we therefore now insist upon and somewhat hardily explain. Those who have spent all their time in the learning and searching out the mysteries of Naturall Philosophy, would have all men think and beleve, that the foure Elements have such mutuall sympathy, that they may be changed each into other; so that they not only undergoe the alterations of the first qualities which are heat, coldness, dryness and moisture, but also the mutation of their proper substances by rarefaction and condensation. For thus the fire is frequently changed into air, the air into water, the water into air, and the water into earth; and on the contrary, the earth into water, the water into air, the air into fire; because these 4. first bodies have in their common matter enjoyed the contrary and fighting, yet first and principall qualities of all.

Whereof we have an example in the * Ball-bellows brought out of Germany, which are made of brass, hollow and round; and have a very small hole in them, whereby the water is put in, and so put to the fire; the water by the action thereof is rarified into air, and so they send forth wind with a great noise, and blow strongly as soon as they grow throughly hot. You may try the same with Chestnuts, which cast whole and undivided into the fire, presently fly asunder with a great crack; because the watry and innate humidity turned into wind by the force of the fire, forcibly breaks his passage forth. For the air or wind raised from the water by rarefaction, requires a larger place, neither can it now be contained in the narrow filmes, or skins of the Chestnut, wherein it was formerly kept. Just after the same manner Gunpowder being fiered, turns into a far greater proportion of air, according to the truth of that Philosophicall proposition, which saith, Of one part of earth, there are made ten of water; of one of water, ten of air; and of one of air are made ten of fire. Now this fire, not possible to be pent in the narrow space of the peice, wherein the powder was formerly contained, endeavours to force its passage with violence, and so casts forth the Bullet lying in the way, yet so that it presently vanishes into air, and doth not accompany the Bullet to the mark, or object, which it batters, spoiles and breaks asunder. Yet the Bullet may drive the obvious air with such violence, that men are often sooner touched therewith than with the bullet, and dye by having their bones shattered and broken without any hurt on the flesh which covers them; which as we formerly noted, it hath common with Lightning. We find the like in Mines, when the powder is once fiered, it removes & shakes even mountains of earth.

In the year of our Lord 1562. a quantity of this powder which was not very great taking fire by accident in the Arcenall of Paris, caused such a tempest, that the whole City shooke therewith; but it quite overturned divers of the neighbouring houses, and shook off the tyles and broke the windowes of those which were further off; & to conclude, like a storme of Lightning it laid many here and there for dead, some lost their sight, others their hearing, and other some had their limbs torn asunder as if they had been rent with wild horses; and all this was done by the only agitation of the air into which the fiered Gunpowder was turned; just after the same manner as windes pent up in hollow places of the earth which want vents. For in seeking passage forth, they vehemently shake the sides of the Earth, and raging with a great noise about the cavities, they make all the surface thereof to tremble; so that by the various agitation one while up, another down, it overturnes or carries it to another place. For thus we have read that *Megara* and *Agina* anciently most famous Cities of Greece were swallowed up and quite overturned by an earthquake; I omit the great blusterings of the windes striving in the cavities of the earth, which represent to such as heare them at some distance, the fierce assailing of Cities, the bellowing of Bullets, the horrid roarings of Lions, neither are they much unlike to the roaring reports of Cannons. These things being thus premised let us come to the thing we have in hand. Amongst things necessary for life, there is none causes greater changes in us than the air; which is continually drawn into the Bowells appointed by nature, and whether we sleep, wake, or what else soever we do, we continually draw in, and breath it out. Through which occasion *Hippocrates* calls it Divine, for that breathing through this mundane Orbe, it embraces, nourishes, defends and keeps in quiet peace all things contained therein, friendly conspiring with the stars from whom a divine vertue is infused therein. For the air diversly changed and affected by the stars, doth in like manner produce various changes in these lower mundane bodies. And hence it is that Philosophers and Physitians do so seriously with us to behold and consider the culture and habit of places, and constitution of the air, when they treat of preserving of health, or curing diseases. For in these the great power and dominion of the air is very apparent, as you may gather by the foure seasons of the year; for in summer the air being hot and dry, heats and dries our bodies; but in winter it produceth in us the effects of winters qualities, that is, of cold and moisture; yet by such order and providence of nature, that although according to the varieties of seasons our bodies may be variously altered, yet shall they receive no detri-

A History.

Why the wounds made by Gunshot some few years agoe were so deadly.

The cause of the transmutation of the Elements.

* These bellows here mentioned by the Author, are

Balls made of Brass in form of a pear, with a very small hole in their lesser ends: when you would fill them with water you must heat them very hot, and so the air which is contained in them will be exceedingly rarified, which by putting them presently into water will be condensed as much, and so will draw in the water to supply the place, *ne detur vacuum*. Then put them into the fire, & it again rarifying the water into air will make them yeeld a strong continued, and forcible blast. The cause of the report and blow of a Cannon. A History. The cause of an Earthquake.

triment thereby, if so be that the seasons retain their seasonableness; from whence if they happen to digress, they raise and stir up great perturbations both in our bodies and minds; whose malice we can scarce shun, because they encompass us on every hand, and by the law of nature enter together with the air into the secret cabinets of our bodies both by occult and manifest passages. For who is he, that doth not by experience find both for the commodity and discommodity of his health, the various effects of winds, (wherewith the air is commixt) according as they blow from this or that Region, or quarter of the world. Wherefore seeing that the South wind is hot and moist; the North wind cold and dry; the East wind clear and fresh; the West wind cloudy; it is no doubt but that the air which we draw in by inspiration carries together therewith into the bowells the qualities of that wind which is then prevalent. When we read in *Hippocrates*, that changes of times, whether they happen by different winds, or vicissitude of seasons, chiefly bring diseases; For northerly winds do condense, and strengthen our bodies, and make them active, well coloured and daring, by resuscitating and vigorating the native heat. But southern winds resolve and moisten our bodies, make us heavy headed, dull the hearing, cause giddiness, and make the eyes and body less agile; as the Inhabitants of *Narbon* find to their great harme, who are otherwise ranked among the most active people of France. But if we would make a comparison of the seasons and constitutions of a year, by *Hippocrates* decree, Droughts are more wholesome and less deadly than Rains; I judg for that too much humidity is the mother of putrefaction, as you learn by these countries which are blown upon by a wind from Sea. For in these flesh which is kept for food, putrefies in the space of an houre; and such ulcers as in other places are easily and quickly healed, do there by the conflux and collection of matter become inveterate & contumacious. Therefore as when the seasons of the year successively fall out agreeable to their nature, & when each season is seasonable, then either we are not sick at all, or assuredly with less danger. So on the contrary the perfect constitution and health of our bodies becomes worse and decays, when the seasons of the year are depraved and perverted in time and temper. Now seeing that these many years the four seasons of the year have wanted their seasonableness, the summer wanting his usuall heat, and the winter its cold, and all things by moisture and the dominion of the southern winds have been humid and languid, I think there is none so ignorant in naturall Philosophy and astrology, who will not think that the causes of the malignitie and contumacy of those diseases which have so long afflicted all France, are not to be attributed to the air and Heavens. For otherwise, whence have so many pestilent and contagious diseases tyrannized over so many people of every age, sex and condition? whence have so many catarrhes, coughs and heavinesses of the head, so many plurisies, tumors, small poxes, meazells, and itches not admitting of digestion and remedies prescribed by Art? Whence have we had so many venomous creatures, as Toads, Grasshoppers, Caterpillars, Spiders, Waspes, Hornets, Beetles, Snails, Vipers, Snakes, Lizards, Scorpions and Efts or Nutes, unless from excessive putrefaction which the humidity of the air, our native heat being liquid and dull, hath caused in us, and the whole kingdome of France? Hence also proceeds the infirmity of our native heat, and the corruption of the blood and humors whereof we consist, which the rainy Southwind hath caused with its sultry heat. Wherefore in these last years I have drawn little blood, which hath not presently shewed the corruption of its substance by the black or greenish colour, as I have diligently observed in all such as I have bled by the direction of Physicians, either for prevention of future, or cure of present diseases. Whence it comes to passe that the fleshy substance of our bodies could not but be faulty both in temper and consistence; seeing that the blood whence it is generated had drawn the seeds of corruption from the defiled air. Whence it fell out, that the Wounds which happend with losse of substance could be scarce healed or united, because of the depraved nature of the blood. For so the Wounds and ulcers of these which are troubled with the Dropsie, whose blood is more cold or wholly waterish; so of Leprous persons, whose blood is corrupt, and lastly of all such as have their bodies replete with ill juice, or else are Cachectick, will not easily admit of cure. Yea assuredly if but the very part which is hurt swerve from its native temper, the Wound will not easily be cured. Therefore seeing all these things, both the putrefaction of the Air, and depraved humors of the body, and also the distemper of the affected parts conspired together to the destruction of the wounded, what marvail was it, if in these late civill warres, the Wounds which were for their quantitie small, for the condition of the wounded parts but little, have caused so many and grievous accidents and lastly death it self? Especially, seeing that the Air which encompasseth us, tainted with putrefaction corrupts and defiles the Wounds by inspiration and expiration, the body and humors being already disposed, or inclined to putrefaction. Now there came such a stink, which is a most assured sign of putrefaction, from these Wounds, when they were dressed, that such as stood by could scarce endure it, neither could this stink be attributed to the want of dressing, or fault of the Chirurgion; for the Wounds of the Princes and Nobility stunk as ill as these of the common Souldiers. And the corruption was such, that if any chanced to be undrest for one day, which sometimes happened amongst such a multitude of wounded persons, the next day the Wound would be full of wormes. Besides also, which furthermore argues a great putrefaction of humors, many had abscesses in parts opposite to their Wounds, as in the left knee, when as the right shoulder was wounded; in the left arm, when as the right leg was hurt. Which I remember befell the King of *Navarre*, the Duke of *Nevers*, the Lord *Rendan* and divers others. For all men had nature so overcharged with abundance of vicious humors, that if it expelled not part thereof by impostumes to the habit of the body, it certainly otherwise disposed of it amongst the inner parts of the body; for in dissecting dead bodies, we observed that the Spleen, Liver, Lungs, and other Bowells were purulent, and hence it was that the patients by reason of vapours sent from them to the heart were troubled with continuall feavers. But the Liver and all the veinous parts being polluted, & so the generation of the laudable blood hindered, they languished for want of fitting nourishment. But when the Brain by vapours was drawn in to sympathize with the

rest, they were molested with Ravings and Convulsions. Wherefore if any thing succeeded unprosperously in so great malignancy of wounds, the Chirurgeon was not to be blamed, for that it were a crime to fight against God and the Air, wherein the hidden scourges of the divine justice lye hid. Therefore if according to the mind of the great Hippocrates, who commands to bring all contused Wounds to suppuration, that so they may be healed, we indeavoured to cure with such medicins Wounds made with Gunshot, and therefore contused; who can rightly be angry with us, if we performed it not so well, by reason of these putrefactions, gangrenes, and mortifications which proceeded from the corrupt Air, for all that we used not only suppuratives, but were oft-times forced to use other medicins; so long turning aside from the cure of the disease, untill we had overcome the symptoms which much endanger the Patient, and customarily happen upon such Wounds, as also upon those which are made with a sword or any other kind of weapon; as shall plainly appear in the following treatise, to which it now seems high time that we betake our selves.

All contused wounds must be brought to suppuration

CHAP. I. *A division of wounds drawn from the variety of the wounded parts, and the Bullets which wound.*

Wounds which are made in mans body by Gunshot, whether simple or compound, are accompanied with contusion, dilaceration, distemper and swelling. I say, all these possess either the noble parts, or ignoble, the fleshy, nervous or bony, some whiles with rending and tearing asunder the larger vessells; sometimes without harming them. Now these Wounds are only superficial, or else pierce deep and pass quite through the body. But there is also another division of these Wounds taken from the variety of the Bullets wherewith they are made. For some Bullets are bigger, some less, some between both, they are usually made of lead, yet sometimes of steel, iron, brass, tin, scarce any of Silver, much less of Gold. There arises no difference from their figure; for almost all kinds of Wounds of this nature are round. From these differences, the Chirurgeon must take his Indications what to do, and what medicins to apply. The first care must be, that he think not these horrid and malign symptoms, which usually happen upon these kinds of Wounds, to arise from combustion, or poison carried with the Bullet into the wounded part, and that for these reasons we have formerly handled at large. But rather let him judge they proceed from the vehemency of the contusion, dilaceration and fracture, caused by the Bullets too violent entry into the nervous and bony bodies. For if at any time the Bullet shall only light upon the fleshy parts, the Wounds will be as easily cured, as any other Wound usually is, which is made with a contusing and round kind of weapon, as I have often found by frequent experience, whilst I have followed the wars, and performed the part of a Chirurgeon to many Noblemen and common Souldiers, according to the counsell of such Physitians as were there overseers of the cure.

A division of wounds from the variety of the wounded parts. From the difference of Bullets, Wounds made by Gunshot are usually round.

CHAP. II. *Of the signs of Wounds made by Gunshot.*

Wounds made by Gunshot are known by their figure, which is usually round; by their colour, as when the native colour of the part decays, and in stead thereof a livid, greenish, violet or other colour succeeds; by the feeling or sense of the stroke, when in the very instant of the receiving thereof, he feels a heavy sense as if some great stone, or piece of timber, or some such other weighty thing had fallen upon it; by the small quantity of blood which issues out thereat, for when the parts are contused, within some small while after the stroke they swell up, so that they will scarce admit a Tent, whence it is that the blood is stopped, which otherwise would flow forth of the orifice of the Wound; by heat, which happens either by the violentness of the motion, or the vehement impulsion of the air, or the attrition of the contused parts, as the flesh and nerves. Also you may conjecture that the Wounds have been made by Gunshot, if the bones shall be broken, and the splinters thereof by pricking the neighbouring bodies cause defluxion and inflammation. But the cause that the Bullet makes so great a contusion is, for that it enters the body not with any points or corners, but with its round and sphericall body, which cannot penetrate but with mighty force; whence it cometh to pass that the wound looks black, & the adjacent parts livid: hence also proceed so many grievous symptoms, as pain, Defluxion, inflammation, Apostumation, Convulsion, Phrensie, Palsie, Gangrene and mortification, whence lastly death ensues. Now the Wounds do often cast forth virulent and very much stinking filth, by reason of the great contusion, and the rending and tearing of the neighbouring particles. A great abundance of humors flow from the whole body, and fall down upon the affected parts, which the native heat thereof being diminished, forsakes, and presently an unnatural heat seizes upon it. Hither also tend an univerfall or particular repletion of ill humors, chiefly if the Wounds possess the nervous parts as the joints. Verily neither a Stag with his horn, nor a flint out of a sling can give so great a blow, or make so large a Wound, as a Leaden or Iron Bullet shot out of a Gun, as that which going with mighty violence, pierces the body like a Thunderbolt.

Signs of wounds from their figure. From their colour. From the feeling the blow. From the bleeding. From the heat of the wound. Whence these wounds are so much contused.

CHAP. III. *How these Wounds must be ordered at the first dressing.*

The Wound must forthwith be enlarged, unless the condition of the part resist, that so there may be free passage forth both for the Sanies, or matter, as also for such things as are forced, or otherwise contained therein; such as are pieces of their cloaths, bombast, linnen, paper, pieces of Mail or Armour, Bullets, Hail-shot, splinters of bones, bruised flesh and the like, all which must be plucked forth with as much celerity and gentleness as may be. For presently after the receiving of the Wound the pain and inflammation are not so great, as they will be within a short time after. This is the principall thing in performance of this work, that you place the Patient just in such a posture as he was in at the receiving of the Wound; for otherwise the various motion and turn-

Strange bodies must first be pulled forth.

The manner how to draw them forth.

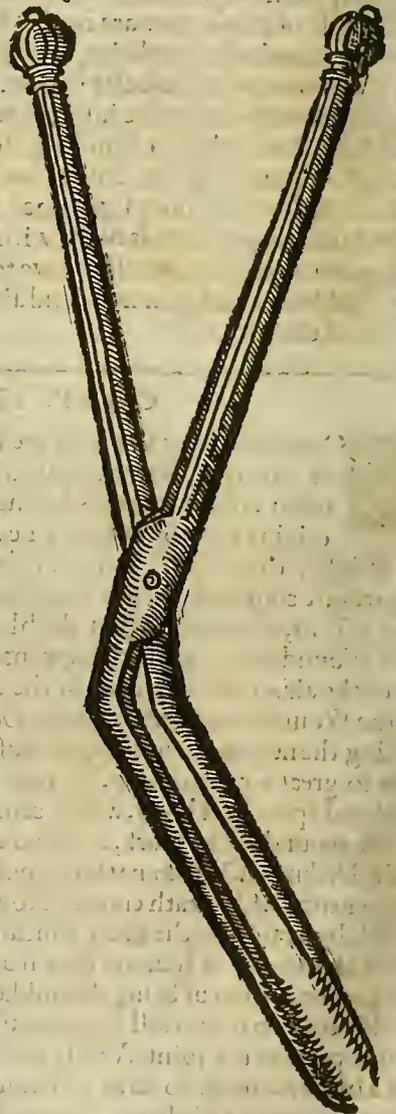

ing of the Muscles will either hinder or straiten the passage forth of the contained bodies. You shall if it be possible, search for these bodies with your finger, that so you may the more certainly and exactly perceive them. Yet if the bullet be entred somewhat deep in, then you shall search for it with a round and blunt probe, lest you put the Patient to pain; yet oftentimes you shall scarce by this means find the Bullet. As it happened to the Marshall of *Brissac* in the siege of *Parpignan*, who was wounded in his right shoulder with a Bullet, which the Chirurgeons thought to have entered into the capacity of his body. But I, wishing the Patient to stand just in the same manner as he did when he received the Wound, found at length the place where the Bullet lay, by gently pressing with my fingers, the parts near the Wound, and the rest which I suspected; as also by the swelling, hardness, pain and blackness of the part, which was in the lower part of the shoulder near unto the eight or ninth spondill of the back. Wherefore the Bullet being taken forth by making incision in the place, the Wound was quickly healed, and the Gentleman recovered. You shall observe this, and rather beleve the judgment of your fingers, than of your Probe.

CHAP. IIII. A description of fit Instruments to draw forth Bullets and other strange bodies.

Both the magnitude and figure of Instruments fit for drawing forth of Bullets and other strange bodies, are various according to the diversity of the incident occasions. For some are toothed, others smooth, others of another figure and bigness; of all which sorts the Chirurgeon must have divers in a readines, that he may fit them to the bodies and Wound, and not the Wounds and bodies to his Instruments.

The Delineation of such like Instruments.

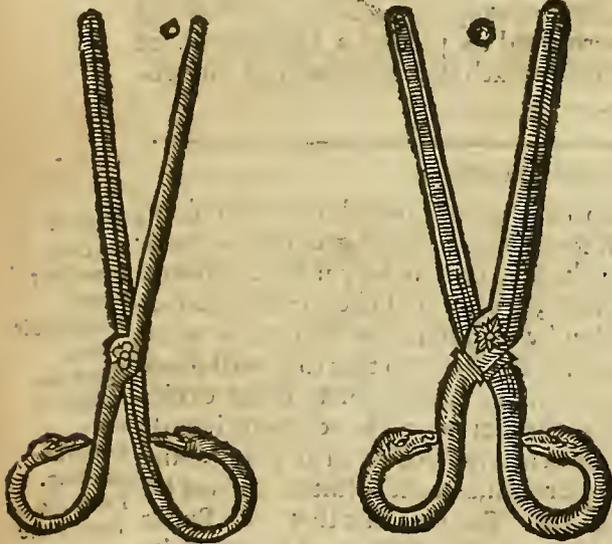

The crooked Cranes-bill, with teeth like a Saw.

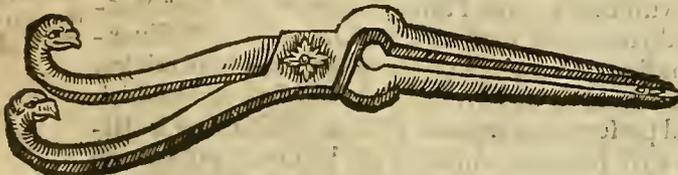

The straight Cranes-bill being also toothed, fit for drawing forth hail-shot, pieces of armour, splinters of bones, and such things as lye deep within.

The Ducks-bill.

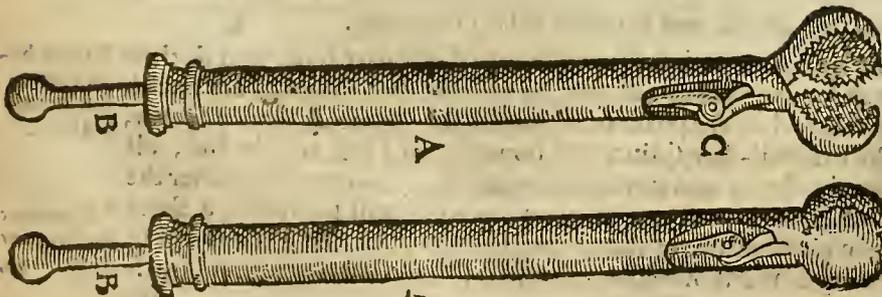

This Ducks-bill hath a large round and toothed cavity in the end, for so it more easily taketh hold of the Bullet when it lies amongst much Flesh.

A toothed Crowes-Bill.

Another Instrument fit for drawing forth of Bullets, which may be termed a Catch-Bullet.

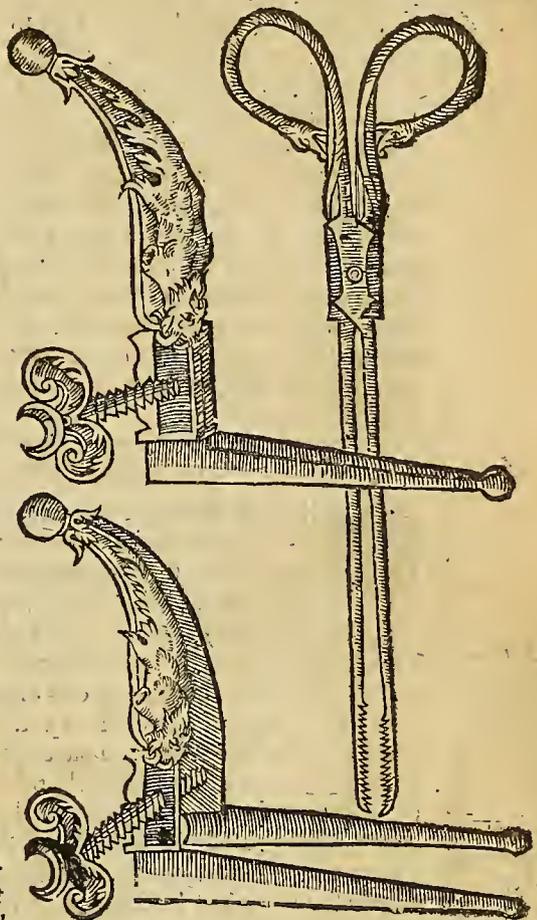

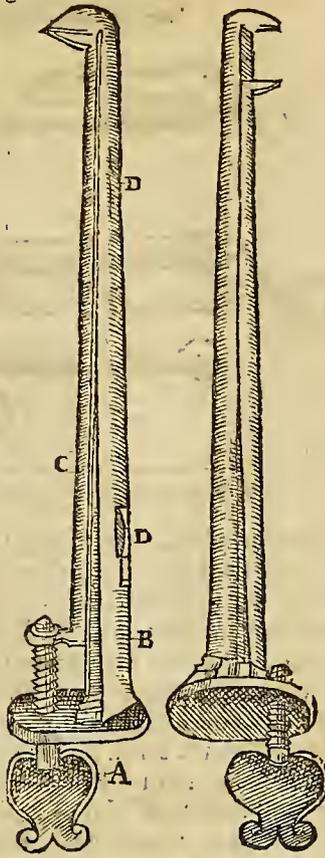

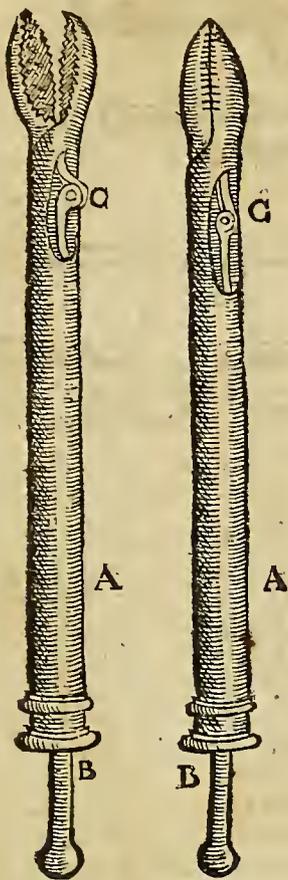

A. Shews the Trunk.
B. Shews the rod, or string which opens and shuts the joint.
C. The joint.

Another

Another Catch-Bullet called a Lizards-nose, made for drawing out of bullets which are somewhat flatted, by striking upon a bone.

The Parrots-beak is made for drawing forth pieces of mail thrust into the flesh, or bones; and this is the figure thereof.

The Swans bill opens with a screw; you may with this dilate the Wounds, and so put in a straight Cranes-bill, as pincers to pluck forth strange bodies. The figure of both are here exprest.

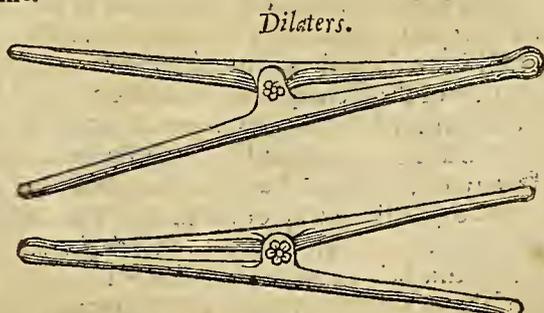

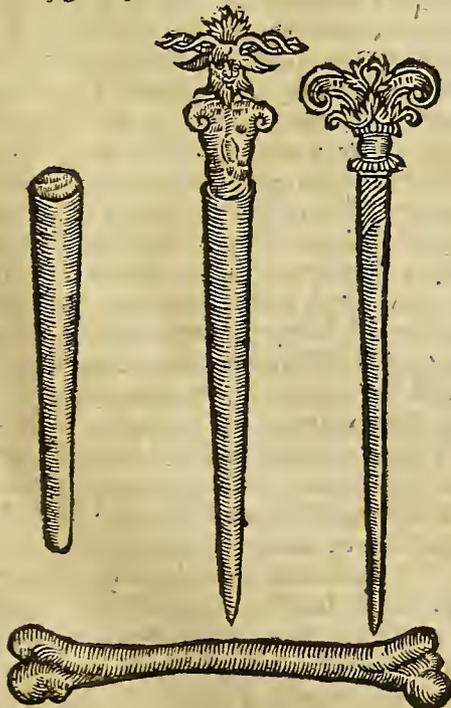

A. Shews the screw pin. B. The hollowed part which receives the round part noted with. C. Which is opened and shut by the screw. D. D. Falls, or stays, which govern the running branch.

be not too deep in the Wound, they may be taken forth with your Levatory, or else by the help of these Gimblets. These Gimblets are screwed into their pipes, or canes, and enter with their screwed points into the Bullets, if that they be of Lead or Tin, and of no harder metall; and so being fastened in them, bring them out with them.

The figure of the Gimblet with his pipe or cane.

Besides the Swans-bill which we lately mentioned, there are also other instruments fit to dilate and open the Wounds, therefore called Dilaters, by whose help the Wound may be held open, that so the hidden bodies may be seen; for when you press together the two ends of this Instrument, the other two open and dilate themselves. You may also use them in dilating divers other parts of the body, as the Nostrils, Fundament, and such like.

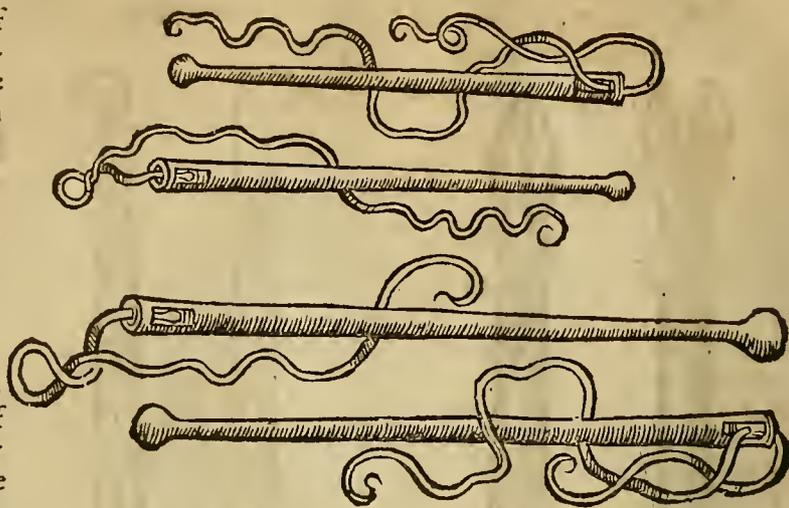

The Instruments which follow are called Seton needles, or Probes; whose use is, to draw through a flannula, so to keep the Wound open, that you may the better take forth any strange body. Besides also we use the same needles to search, or as it were to sound the deepness of the Wounds, and to find out the Bullets. For they cannot

put one to much pain because they have smooth and round ends. So also all Probes wherewith we

What probes fit to search the fe wounds,

search for Bullets, must have somewhat large, smooth and round ends. For seeing that the verges of the Wound meet together presently after the hurt, if the Probes be too smal or slender, they will stick in the inequality of the flesh, neither will they be able to come to the Bullet. But if they be sharp & pointed, they will cause and renew the pain by pricking the flesh they meet withall, & so hinder your intention of finding the Bullet; Now you must be furnished with these instruments of a different length, according to the various thicknesse of the parts; for you cannot put any through the thigh but such as are of good length.

Probes for to put flammulaes through a Wound withall.

CHAP. IX. *What dressing must first be used, after the strange bodies are pluckt or drawn out of the Wound.*

When the strange bodies are drawn or pluckt out of the Wound, by these means we have formerly recited, the chief of the cure must be to heal the contusion, and amend the distemper of the air if it be hot and moist, that is, subject to putrefaction. This shall be done by medicins taken inwardly, applied outwardly, and put into the Wound. Things to be inwardly used in diet and Pharmacy I leave to the judgment of learned Physitians; for the particular and topick medicins, (unless from the present constitution of the air, the condition of the wounded part, or from some other cause there be danger of a Gangrene) you must use suppuratives, as you usually do in contusions; such as are oil of Whelpes and that which we call a digestive; you must chiefly forbear suppuratives, when as the wounded part is of a nervous nature. For all nervous parts require dryer medicins than fleshy, as we have formerly delivered speaking of Wounds of the joints; wherefore in Wounds of the joints and nervous parts you shall use more venice Turpentine than oil. *Laurentius Iobertus* the Kings Physitian & Chancellour of the University of Mompelier, in a treatise which he writ of Wounds made with Gunshot, forbids the use of Escharoticks both actual and potentiall, in these Wounds, if simple; for that they induce pain, inflammation, a fever, Gangrene and other deadly symptomes. Besides also an eschar will hinder suppuration, which is to be desired in this kind of Wounds, that so the contused flesh may be severed from the sound, lest it be drawn to putrefaction by contagion. Which easily happens when an Eschar is drawn, as a bar over it, for then the excrementitious humor remains longer in the part, and the putredinous vapours hindered from passing forth, are encreased, and carryed from the lesser vessels to the bigger, and so over all the body. Wherefore, when you suspect putrefaction, letting alone suppuratives, use in the first place such things as resist putrefaction, as this following ointment. *Rx pulver. alumin. rocha, viridis aris, vitrioli romani, mellis rosat. an. ʒij. aceti boni quantum sufficit, bulliant omnia simul secundum artem, & fiat medicamentum ad formam mellis.* This by reason of the heat and subtlety of the substance, hath a faculty to induce and attenuate the humors, as also to call forth the native heat drawn in & dissipated by the violent and forcible entrance of the Bullet into the body; furthermore also it corrects the venomous contagion of the virulent humor. Now this medicine shall be used, dissolved in Venegar or *aqua vitæ*, and be put into the Wound with tents, or pledgets. The tents which shall be used at the first dressing must be somewhat long and thick, that by dilating the Wound, they may make way for application of other remedies; otherwise you may make injection with a syringe, that so it may penetrate the more powerfully. But this described *Ægyptiacum* shall be tempered according to the condition of the affected parts, for the nervous parts will be offended with it as being too acrid; but it may be qualified by admixture of oil of Turpentine & Saint Iohn-wort. Also we may well be without this *Ægyptiacum* when there is no such pestilent constitution of the air, as was seen in the late Civill wars. After the use of *Ægyptiacum* you shall with emollient & lenitive medicins procure the falling away of the Eschar, & such a medicine is this following oil, being somewhat more than warm. *Rx Olei violati lib. iiii. in quibus coquantur catelli duo nuper nati, usque ad dissolutionem ossium, addendo vermium terrestrium, ut decet preparatorum, lb. j. coquantur simul lento igne, deinde fiat expressio ad usum, addendo terebinth. venet. ʒiij. aquæ vitæ ʒj.* This oil hath a wonderfull force to assuage pain, to bring the Wound to suppuration, & cause the falling away of the Eschar. This ensuing oil is made more easily. *Rx olei seminis lini, & liliior. an. ʒiij. unguent. baslic. ʒj. liquefiant simul & fiat medicamentum;* put of this a sufficient quantity into the Wound; for this being applyed indifferent hot, hath power to assuage Pain, to soften and humect the orifice of the wound, and help forwards suppuration, which is the true manner of curing these kind of Wounds; according to the rule of *Hippocrates*, which wishes every contused wound to be presently brought to suppuration, for so it will be lesse subject to a Phlegmon; and besides, all the rent & bruised flesh must putrefie, dissolve and turn to quitture, that new and good flesh may be generated in stead thereof. *Laurentius Iaubertus* much commends this following medicine, of whose efficacy, as yet, I have made no triall. *Rx pulver. mercur. bis calcinati, ʒj. adipis porci recentis, vel butyri recentis, ʒviij. Camphoræ in aqua vitæ dissolutæ, ʒij. misce omnia simul, addendo tantillum olei liliorum, aut lini.* Experience taught him, and reason also shewes, that this kind of remedy is very commendable; for the powder of Mercury, if mixed with

A Caution in the use of suppuratives,

The oil of VWhelpes a digestive, anodyne, and fit medicine to procure the falling away of an Eschar. *Lib. de ulcer.*

The faculties of the powder of Mercury.

a grosse and humecting matter, doth in a short space turn the bruised flesh into *pus*, without causing any great pain. For the Camphire, whether it be hot or cold, in temper, it much conduces to that purpose, by reason of the subtlety of the parts, whereof it consists. For by means of this quality the medicines enter with more facility into the affected bodies, and perform their parts; besides also Camphire resists putrefaction. Some drop into the Wound *aqua vitæ*, wherein they have dissolved some calcined vitrioll. Which kind of remedy is not suppurative, but yet much resists putrefaction, so that we may use it with good success, when the weather is hot, moist, and foggie. But when the Wound is made very neer at hand, it cannot but be burnt by the flame of the powder; in which remedies used for burns, will be usefull, not omitting such as are fit for contusions. But for these parts which lye next the Wound, you shall not, unless at the first dressing, apply refrigerating and astringent things, but rather emollient and suppurative. For those things which have a refrigerating faculty, weaken the part, and hinder supuration. For astringents consipate the skin, which is the cause, that the putrid vapours shut up and hindred from transpiration and passage forth, a gangrene and mortification easily seize upon the part. But if the contusion be great and diffuse it self more largely over the flesh, the part must be much scarified; that so the contused and concreat blood, and therefore subject to putrefaction, may be evacuated. But for these parts, which somewhat further distant from the Wound encompass the contused flesh, they require refrigerating and strengthening medicins, so to hinder the falling down and setting of the humor in that part which is this ensuing medicine. *Rx pul. boli. armen. sanguin. Dracon. Myrrha, an. ʒj. succi solan. semperivi. portulac. an. ʒij. ʒ. album iij. ovorum. oxyrhodin. quantum sufficit; fiat linimentum, ut decet.* You may use this, & the like untill the suspected symptome be past fear. Neither must you have less care, of binding up and rolling the part, than of your medicins; for it doth not a little conduce to the cure, to bind it so fitly up as it may be without pain. The Wound at the beginning of the cure, must be dressed but once in 24 houres, that is, untill the Wound come to supuration; but when the quittance begins to flow from it, and consequently the pain and feaver are encreased, it shall be dressed twice a day, that is, every twelve houres. And when the quittance flowes more abundantly than usuall, so that the collection thereof is very troublesome to the Patient, it will be requisite to dresse it every 8 houres; that is, thrice a day. Now when as this abundant efflux is somewhat flaked, and begins to decrease, it will suffice to dresse it twice a day. But when the ulcer is filled with flesh, and consequently casts forth but little matter, it will serve to dresse it once a day, as you did at the first.

The force of calcined vitriol. How wounds made by Gunshot may be combust.

Scarification.

An Astringent repelling medicine.

The binding up.

How oft the wound must be dressed in a day.

CHAP. VI. How you shall order it at the second dressing.

AT the second and following dressings, unless you suspect putrefaction, and a Gangrene, you shall only put into the Wound some of the oils formerly described, adding to them the yolks of some eggs and a little saffron; and use this medicin, untill the Wound come to perfect supuration. Here you must note this, that these kinds of Wounds are longer before they come to supuration, than other Wounds made by any other sort of weapon; both for that the bullet, as also the air which it violently carries before it, by much bruising the flesh, on every side, dissipates the native heat, and exhausts the spirits of the part. Which things hinder digestion, and often cause the matter to stink, as also many other pernicious symptomes. Yet most usually *pus* or quittance appears within three or four dayes, sooner and later according to the various complexion, and temperament of the Patients bodies, and the condition of the ambient air in heat and cold. Then by little and little you must come to deterfives, adding to the former medicin some Turpentine washed in Rose, Barly, or some other such like water, which may wash away the biting thereof. If the incompassing air be very cold, you may to good purpose, add some *aqua vitæ*; for by Galens prescript, we must not use hot medicins in winter, & less hot in summer. Then in the next place use deterfives, as *Rx. aquæ decoctionis hordei quantum sufficit, succi plantaginis, apii, agrimon. centaurei minoris, an. ʒj. bulliant omnia simul, in sine decoctionis adde terebinthina venetæ ʒ iij. mellis rosat. ʒ ij. farin. hordei ʒ iij. croci ʒ j.* Let them be all well mixed together and make a Mundificative of an indifferent consistence. Or *Rx succi clymeni, plantag. absinth. apii, an. ʒ ij. tereb. venet. ʒ iij. syrup. absinth. & mellis ros. an. ʒ ij. bulliant omnia secundum artem, postea coentur, in colatura adde pulver. aloes, mastiches, Ireos Florent. far. hord. an. ʒ j. fiat Mundificativum ad usum dictum.* Or else *Rx. terebinth. venet. lotæ in aq. ros. ʒ v. olei ros. ʒ j. mellis ros. ʒ iij. myrrhæ, aloes, mastich. aristoloch. rotundæ, an. ʒ i ʒ. far. hord. ʒ iij. misce.* Make a Mundificative, which you may put into the Wound with tents, but such as are neither too long, nor thick, lest they hinder the evacuation of the quittance and vapours, whence the wounded part will be troubled with erosion, pain, defluxion, inflammation, abscess, putrefaction; all which severally of themselves, as also by infecting the noble parts, are troublesome both to the part affected, as also to the whole body besides. Wherefore you shall put into the Wound no tents, unless small ones, and of an indifferent consistence; lest (as I said) you hinder the passing forth of the matter, or by their hard pressing of the part, cause pain, and so draw on malign symptomes. But seeing tents are used both to keep open a Wound so long, untill all the frange bodies be taken forth, as also to carry the medicins, wherewithall they are anointed: even to the bottom of the Wound. Now if the Wound be sinuous and deep, that so the medicin cannot by that means arrive at the bottom and all the parts thereof, you must do your business by injections made of the following decoction. *Rx. aq. hord. lib. 4. agrimon. centaurei minor. pimpinellæ, absinth. plantag. M. ʒ. rad. aristoloch. rotund. ʒ ʒ. fiat decoctio ad lib. j. in colatura expressa dissolve aloes hepaticæ, ʒ iij. mellis ros. ʒ ij. bulliant modicum.* Inject some of this decoction three or four times into the Wound, as often as you dress the Patient; and if this shall not be sufficient to cleanse the filth, and waite the spongius, putrid and dead flesh, you shall dissolve therein as much *Ægyptiacum* as you shall think fit for the present necessity; but commonly you shall dissolve an ounce of *Ægyptiacum* in a pint of the decoction. Verily *Ægyptiacum* doth powerfully consume the proud flesh which lies in the capacity

Why wounds made by Gunshot are so long before they come to supuration.

Why Turpentine must be washed.

Meth. A detergent medicine.

Why tents must be neither too long nor thick.

When you must use injections.

An Injection.

The quantity of *Ægyptiacum* to be used in an injection.

capacity of the Wound; besides also it only works upon such kind of flesh. For this purpose I have also made triall of the powder of Mercury, and burnt Alum equally mixed together, and found them very powerfull, even almost as sublimate, or Arsenick, (but that these cause not such pain in their operation.) I certainly much wonder at the largeness of the Eschar which arises by the asperion of these powders. Many Practitioners would have a great quantity of the injection to be left in the cavities of sinuous ulcers, or Wounds; which thing I could never allow of. For this contained humor causeth an unnatural tension in these parts, and taints them with superfluous moisture, whereby the regeneration of flesh is hindered; for that every ulcer as it is an ulcer, requires to be dried, in Hippocrates opinion. Many also offend in the too frequent use of Tents; for as they change them every houre, they touch the sides of the Wound, cause pain, and renew other malign symptoms; wherefore such ulcers as cast forth more abundance of matter, I could wish rather to be dressed with hollow tents, like those I formerly described to be put into Wounds of the Chest. You shall also press a linnen boulder to the bottom of the Wound, that so the parts themselves may be mutually condensed by that pressure and the quittance thrust forth; neither will it be amiss to let this boulder have a large hole fitted to the orifice of the Wound and end of the hollow tent and pipe, that so you may apply a sponge for to receive the quittance, for so the matter will be more speedily evacuated and spent, especially if it be bound up with an expulsive ligature, beginning at the bottom of the ulcer, and so rapping it up to the top. All the boulders and rowlers, which shall be applyed to these kinds of Wounds, shall be dipped in Oxycrate or red wine, so to strengthen the part, and hinder defluxion. But you must have a speciall care, that you do not bind the Wound too hard, for hence will arise pain, hindering the passage forth of the putredinous vapours and excrements, which the contused flesh casts forth; and also fear of an *Atrophia*, or want of nourishment, the alimentary juyces being hindered from coming to the part.

CHAP. VII. By what means strange bodies, left in at the first dressing, may be drawn forth.

 T divers times happens, that certain splinters of bones, broken and shattered asunder by the violence of the stroak, cannot be pulled forth at the first dressing, for that they either do not yeeld or fall away, or else cannot be found by the formerly described instruments. For which purpose this is an approved medicin to draw forth that which is left behind. *R̄ radic. Ireos Floren. panac. & cappar. an. ʒ iij. aristoloch. rotund. manna, thuris, an. ʒ j. in pollinem redacta incorporantur cum melle rosar. & terebinth. venet. an. ʒ ij. or R̄ resin. pini sicca ʒ iij. pumicis combusti & extincti in vino albo, radic. Ireos, aristolochias, an. ʒ β. thuris ʒ j. squame aris, ʒ ij. in pollinem redigantur, incorporantur cum melle rosato, fiat medicamentum.*

CHAP. VIII. Of Indications to be observed in this kind of Wounds.

 He ulcer being clenfed and purged, and all strange bodies taken forth; nature endeavours to regenerate flesh, and cicatrize it, must be helped forwards with convenient remedies, both taken inwardly, and applyed outwardly. To which things we may be easily and safely carryed by indications drawn, first from the essence of the disease, then from the cause; if as yet present it nourish the disease. For that which Galen sayes, *Lib. 3. Meth.* that no indication may be taken from the primitive cause and time; must be understood of the time past, and the cause which is absent. And then from the principal times of the disease, the beginning, increase, state, and declination; for each of these four require their remedies. Others are taken from the temperament of the Patient, so that no Chirurgeon need doubt, that some medicins are fit for cholerick, othersome for phlegmatick bodies. Hither refer the indication taken from the age of the Patient; also it is drawn from his diet, for no man must prescribe any slender diet to one who is alwayes feeding, as to him who is accustomed to eat once, or twice a day. Hence it is that a diet consisting only of *Panada's* is more fit for *Italians* than for *French* men; for we must give somewhat to custome, which is as it were another nature. Vocations and daily exercises, are referred to diet, for other things besit Husbandmen & labourers, whose flesh is dense and skin hardened by much labour, than idle and delicate persons. But of all other, have diligent regard of that indication which is drawn from the strength of the Patient; for we must presently, (all else being neglected) succor the fainting, or decaying strength; wherefore if it be needfull to cut off a member that is putrefied, the operation must be deferred if the strength of the Patient be so dejected, that he cannot have it performed without manifest danger of his life. Also indication may be drawn from the incompassing air, under which also is comprehended that, which is taken from the season of the yeer, region, the state of the air and soil, and the particular condition of the present and lately by-past time. Hence it is we read in *Guido*, that Wounds of the head are cured with far more difficulty at *Paris*, than at *Avignon*; where notwithstanding on the contrary, the Wounds of the legs are cured with more trouble, than at *Paris*; the cause is, the air is cold and moist at *Paris*; which constitution seeing it is hurtfull to the brain and head, it cannot, but must be offensive to the Wounds of these parts. But the heat of the ambient air at *Avignon*, attenuates and dissolves the humors, and makes them flow from above downwards. But if any object that experience contradicts this opinion of *Guido*, and say, that Wounds of the head are more frequently deadly in hot countries; let him understand that this must not be attributed to the manifest and naturall heat of the air; but to a certain malign and venenate humor, or vapor dispersed through the air, and raised out of the Seas; as you may easily observe in those places of *France* and *Italy* which border upon the Mediterranean Sea. An indication may also be drawn from the peculiar temper of the wounded parts, for the musculous parts must be dressed after one, and the bony parts after another manuer. The different sense of the parts, indicates and requires the

Why none of the injection must be left in the wound.

Hollow tents or pipes. The manner of binding up the wound.

Two causes that make strange bodies hard to be taken forth.

The Indication which is drawn from the strength of the Patient is the chiefest of all other.

Why wounds of the head at Paris, and of the legs at Avignon are hard to be cured.

the like variety of remedies; for you shall not apply so acrid medicins to the Nerves and Tendons, as the ligaments which are destitute of sense. The like reason also for the dignity and function of the parts needfull for the preservation of life; for oft-times wounds of the brain, or of some other of the naturall & vitall parts, for this very reason that they are defixed in these parts, divert the whole manner of the cure, which is usually and generally performed in wounds. Neither that without good cause, for oft-times from the condition of the parts, we may certainly pronounce the whole success of the disease; for wounds which penetrate into the ventricles of the brain, into the heart, the large vessels, the chest, the nervous parts of the midriffe, the liver, ventricle, small guts, bladder, if somewhat large are deadly; as also these which light upon a joynt in a body repleat with ill humors, as we have formerly noted. Neither must you neglect that indication which is drawn from the situation of the part, and the commerce it hath with the adjacent parts, or from the figure thereof; seeing that *Galen* himself would not have it neglected. But we must consider in taking these forementioned Indications, whether there be a composition, or complication of the diseases; for as there is one and that a simple indication, of one and that a simple disease, so must the indication be various of a compound and complicate disease. But there is observed to be a triple composition, or complication of affects besides nature; for either a disease is compounded with a disease, as a wound, or a phlegmon with a fracture of a bone; or a disease with a cause, as an ulcer with a defluxion; or a disease with a symptome, as a wound with pain, or bleeding. It sometimes comes to pass, that these three, the disease, cause, and symptome, concur in one case or affect. In artificially handling of which, we must follow *Galen's* counsell, who wishes in complicated and compounded affects, that we resist the more urgent; then let us withstand the cause of the disease, and lastly that affect, without which the rest cannot be cured. Which counsell must well be observed; for in this composition of affects, which distracts the Emperick; but on the contrary, the rati-
 onall Physitian hath a way prescribed in a few & these excellent words, which if he follow in his order of cure, he can scarce miss to heal the Patient. Symptomes truly as they are symptomes, yeeld no indication of curing, neither change the order of the cure; for when the disease is healed, the symptome vanishes, as that which follows the disease, as a shadow follows the body. But symptomes do oftentimes so urge and press, that perverting the whole order of the cure, we are forced to resist them in the first place, as those which would otherwise increase the disease. Now all the formerly mentioned indications may be drawn to two heads; the first is, to restore the part to its native temper; the other is, that the blood offend not either in quantity or quality; for when those two are present, there is nothing which may hinder the repletion, or union of wounds nor ulcers.

CHAP. IX, *What remains for the Chirurgion to do in this kind of Wounds.*

He Chirurgion must first of all be skilfull and labour to assuage pain, hinder defluxions, prescribe a diet in these six things we call not naturall, forbidding the use of hot & acrid things, as also of wine; for such attenuateth humors and make them more apt for defluxion. Therefore at the first let his diet be slender, that so the course of the humors may be diverted from the affected part; for the stomach being empty and not well filled, draws from the parts about it, where-
 by it consequently follows, that the utmost and remotest parts are at the length evacuated; which is the cause, that such as are wounded, must keep so spare a diet for the next dayes following. Venery is very pernicious, for that it inflames the spirits and humors far beyond other motions; whereby it happens that the humors waxing hot, are too plentifully carried to the wounded and over heated part. The bleeding must not be stanchd presently upon receiving of the wound, for by the more plentiful efflux thereof the part is freed from danger of inflammation and fulness. Wherefore if the wound bleed not sufficiently at the first, you shall the next day open a vein, and take blood according to the strength and plenitude of the Patient; for there usually flows no great store of blood from wounds of this nature; for that by the greatness of the contusion and vehemency of the moved air, the spirits are forced in, as also I have observed in those who have one of their limbs taken away with a Cannon bullet. For in the time when the wound is received, there flows no great quantity of blood, although there be large veins and arteries torn in sunder thereby. But on the 4, 5, 6. or some more dayes after, the blood flows in greater abundance, and with more violence, the native heat and spirits returning into the part. The belly must be so qualified, that he may have at the least one stool a day, either by nature, or Art; and if by Art, than rather with a Clyster than purging medicins taken by the mouth, for that the agitation of humors, chiefly in the first dayes of the disease, is to be suspected, lest we increase the defluxion falling down upon the wounded part. Yet *Galen* writes that both the evacuations are here needfull, that is, blood-letting and purging; though the Patient be neither plethorick, nor repleat with ill humors. But the care hereof must be committed to the judgment of the learned Physitian; pain, if joynd with inflammation shall be mitigated, by anointing the parts neer unto the wound with *unguent. nutritum*, composed with the juyce of Plantain, Houfleeke, Nightshade, and the like. *Vnguentum Diacalcithei* described by *Galen* dissolved with vinegar, oil of Poppyes and Roses is of no less efficacy; nor *unguent. de bolo*, nor divers other things of the same faculty, though properly no anodynes, as those which are not hot and moist in the first degree, but rather cold, but yet not so as to have any narcotick faculty. Now these forementioned things assuage pain for that they correct the hot distemper, and stay the acrid and cholerick defluxions, whose violence is more than cold. After the use of repercussives, it will be good to apply this following cataplasmi. *R. Mica panis infuse in lacte vaccino lb̄ j̄ β. bulliant parum addendo olei violacei, & rosar. an. ℥ iij. vitellos ovorum nu. iij. pulver. rosar. rub. stor. chamem. & meliloti, an. ℥ ij. farin. fabar. & hordei an. ℥ j. misce, fiat cataplasma secundum artem.* Also in this case you may easily make a medicin, of bread crums boyled in Oxycrate and oil of Roses. The cure of Tumors if any associate the wound, may

be found in their proper place. Natures motion, whether to suppuration, or any such thing, must still be observed, and helped by the Physician and Chirurgeon, as the ministers and servants thereof.

CHAP. X. Of Bullets which remain in the body, for a long time after the Wound is healed up.

Why Lead
Bullets
lye in the
body so
many years
without
doing any
harm.

Lead Bullets lye in some parts of the body some whiles seaven, eight or more years, so that they neither hinder the agglutination of the Wound, neither doth any other symptom happen thereupon, as I have divers times observed; untill at length by the strength of nature forcing them; and their proper weightiness bearing them downwards, they shew themselves in some lower part, by their swelling or bunching forth, and so must be taken forth by the hand of the Chirurgeon. For they say lead hath a certain sympathy and familiarity with mans body, chiefly the fleshy parts thereof. Wherefore it neither putrefies it self, nor causeth the flesh to putrefie; besides it hath an excellent faculty in cicatrizing old ulcers. But bullets of stone, iron and of any other metall, are of another nature, for they cannot remain any long time in the body without hurt; for Iron will grow rusty, and so corrode the neighbouring bodies, and bring other malign symptoms. Yet a Leaden bullet cannot remain any long time in nervous, or noble parts without danger.

CHAP. XI. How to correct the constitution of the air, so that the noble parts may be strengthened, and the whole body besides.

Ut because as we have formerly told you, there are some times wherein even small Wounds made by Gunshot prove deadly, not by their own fault, but the fault of the air; therefore also the Chirurgeon must have this care, that he correct the aire with all diligence, & reduce it to a certain quality and moderation of substance, and strengthen the noble parts and whole body besides, which may be performed by the following medicins, which are to be taken inwardly and applyed outwardly. In the morning three houres before meat let the Patient take some certain quantity as the Physitian shall think fit of the electuary *Diarrhodon Abbatis*, or *Aromaticum rosatum*, *triasantaloni*, *biamoschum*, *letificans Galeni*, or some such other like. And you shall apply some such Epitheme as is here described to the heart and Liver. *Rx aqua rosar. ℥iiij, aqua buglossæ, aceti boni, an. ℥ij. coriandri preparati ℥β. caryophyll. cortic. citri an. ℥j. sant. rub. ℥β. coralli utriusque ℥β. camphoræ ℥j. croci ℥β. pulver. diarrhod. abbat. ℥ij. theriacæ & Mithridatii an. ℥β. pul. flo. chamem. & meli. an. ℥ij. misce, fiat epithema.* Let it be applyed warm by dipping a scarlet cloath therein. You shall frequently put odoriferous and refrigerating things to the Patients nose, to strengthen the animall faculty, as; *Rx aqua rosar. & aceti boni an. ℥ij. caryophyllorum, nucis moschat. cinamomi conquassatorum, & Theriacæ Galeni, an. ℥j.* Let a linnen rag dipped herein, be now and then put to the Patients nose; for the same purpose he shall carry a Pomander about him, and often smell there. As *Rx ros. rub. violar. an. ℥ij. baccarum myrti, juniperi, santal. rub. an. ℥ij. styracis calamit. ℥ij. aq. rosarum. quantum satis est: liquefiat simul cum cera alba quod sufficit, fiat ceratum ad comprehendendos supra dictos pulveres cum pistillo calido, & ducatur in pomum.* Or *Rx rad. Ireos Florent. major an. calam. aromat. ladani, benzoini, rad. cyperi, caryophyll. an. ℥ij. Moschi, gra. 4. fiat pulvis cum gummi tragacanth. quod sufficit.* Or else. *Rx ladani puri ℥j. Benzoini ℥β. styracis calamit. ℥vj. ircos Flor. ℥β. caryophyll. ℥ij. major an. ros. rub. calami aromat. an. ℥β. in poltinem redigantur omnia, & bulliant cum aqua ros. quantum sufficit; colentur, colata liquefiat cum justa cera alba quantitate, styracis liquidæ, ℥j, fiat ad modum cerati, & cum pistillo fiat pomum, addita moschi ℥j.* Also you may corroborate the animall faculty by application of frontalls, as also procure sleep, and ease the pain of the head; as *Rx aq. ros. ℥ij. olei ros. & papav. an. ℥ij. aceti boni, ℥j. trochis. de camphora, ℥β. fiat frontale.* Linnen rags dipped herein may be applyed to the temples of the forehead, and often renewed; otherwise by their heat, drynesse, and hardness, they will cause watching in stead of sleep. Neither must you in the mean time bind the head too hard, lest by intercepting and hindring the pulsation of the temporall Artery, you encrease the pain of the head. You shall make a fire, in the Patients chamber of odoriferous woods, as Juniper, Bay-tree, the prunings or cuttings of Vines, Rosemary, and Orris roots. For the same purpose, you may sprinkle the floore with sweet water; if the Patient be able to undergoe such cost. As, *Rx majorana, menthe, radic. cyperi, calami aromat. salvia, lavendera, fanicul. thymi, stachad. flor. chamem. melilot. satureia, baccarum lauri, & juniperi, an. M. iiij. pulv. caryophyll. nucis Moschat. an. ℥j. aqua rosar. & vite, an. lib. ij. vini albi boni & odorifici. ℔. x. bulliant omnia in balneo Mariæ ad usum dictum.* You may also make perfumes to burn in his chamber, as thus; *Rx carbonis salicis ℥vij. ladani puri ℥ij. thuris masculi, ligni & baccarum Juniperi, an. ℥j. xyloa- loes, benjoini, styracis calamit. an. ℥β. Nucis moschatæ, santal. citrin. an. ℥ij. caryophyll. styracis liquidæ, an. ℥j. zedoaria, calami aromat. an. ℥j. gummi tragacanth. aqua rosar. soluti, quod sit satis; Make hereof perfumes in what fashion you please. For the rottenness and corruption of bones we will treat thereof hereafter in its due place.*

CHAP. XII. Certain memorable Histories.

Here I thinke good for the benefit of young practitioners, to illustrate by examples the formerly prescribed Method of curing Wounds made by Gunshot. The famous and most valiant Count of Mansfelt, Governour of the Duchy of Luxembourg, Knight of the order of Burgundy, comming to the aide of the French King, was at the battell of Moncontour, where in the conflict he received so great a Wound at the joint of the left arme with a Pistoll bullet, that the bones were shivered and broken in so many peeces, as if they had been laid upon an Anyill and struck with an hammer: hence proceeded many malign symptoms, as cruell and tormenting pain, inflammation, a fever, an œdematous and flatulent tumor of the whole arm even to the fingers end, and a certain inclination to a Gangræne: which to resist, *Nicolas Lambert*, and *Richard Hubert* the Kings Chirurgeons, had

had made many and deep scarifications. But when I came to visit and dress him, by the Kings appointment, and had observed the great stench, and putrefaction, I wished that they would use lotions of *Ægyptiacum* made somewhat stronger than ordinary, and dissolved in vinegar and *aqua vitæ*; and do other things more largely spoken of in the chapter of a Gangrene. For the Patient had also a *Diarrhœa* or flux, whereby he evacuated the purulent, and stinking filth which flowed from his Wound. Which how it might come to pass we will show at large when we come to treat of the suppression of the Urine. For this seemed very absurd to many, because that if this purulent humor flowed out of the arm into the belly, it must needs flow back into the veins, be mixed with the blood, and by its pernicious and contagious passage through the heart and liver, cause exceeding ill symptoms, and lastly death. Indeed he often swooned by the ascent of the filthy vapours raised from the ulcer to the noble parts; which to resist, I wished him to take a spoonfull of *aqua vitæ* with some Treacle dissolved therein. I endeavoured to repress the œdematous and flatulent Tumor, possessing all the arme with stoups dipped in oxycrate, to which was put a little salt and *aqua vitæ*; these stoups I stayed and held to the part with double cloaths, sowed as strait as I could. Such a compression held the broken bones in their places, pressed their *Sanies* from the ulcers, and forced back the humors flowing to the part into the center of the body. If at any time I omitted this compression, the tumor was so' encreased, that I was in a great deal of fear, lest the native heat of the part should be suffocated. Neither could I otherwise bind up the arm by reason of the excessive pain which molested the Patient upon the least stirring of the Arm. There were also many Abscesses about his elbow and over all his arm besides. For the letting forth of whose matter I was forced, to make new incisions; which he endured very stoutly. At length I cured him with using a vulnerary potion, and by cleansing the ulcers, and correcting the putrefaction with *Ægyptiacum* dissolved in wine or honey of roses, and so poured into the ulcers, and repressing the growth of proud flesh, with the powder of burnt Alum, drying it after the detersion with liniments. Now this I can truly affirm and profess, that during the time of the cure, I took out above threescore splinters of bones, and those necessarily, amongst which there was one of the length of ones finger; yet by Gods assistance at length he became sound in all things, but that he could not put forth, or draw in his arm.

Matter may flow from the wound - ded limbs into the belly.

A brief recital of the manner of the cure.

Not long after by the Kings command I went to see *Charles Philip* of Croy, Lord of Auret, the Duke of Aschos brother, not far from Mounts a City of Henalt. He kept his bed seven months by reason of a Wound made by a Bullet the space of three fingers above his knee. When I came to him, he was afflicted with these symptoms, intolerable pain, a continuall fever, cold sweats, watchings, excoriation of the hippes by reason of his long lying upon them, his appetite dejected with much thirst. He oft sunk down as if he had the falling sickness, had a desire to vomit, and a continuall trembling or shaking so that he could not put one hand to his mouth without the assistance of the other: he swooned frequently by reason of the vapours ascending to the noble parts. For the thighbone was broken long-ways and sideways with many splinters of bones, whereof some were plucked out and others remained sticking fast in. He besides also had an ulcer in his groin which reached to the midst of his thigh, & many other sinuous ulcers about his knee. All the muscles of his thigh and leg were swoln with a flegmatick, cold and flatulent humor, so that almost all the native heat of those parts seemed extinct. All which things being considered, I had scarce any hope to recover him, so that I repented my coming thither. Yet at length putting some confidence in his strength, and prime of youth, I began to have better hopes. Therefore with his good liking, first of all I make two incisions, so to let forth the matter, which lying about the bone did humect the substance of the muscles. This had happy success, and drew out a great quantity of matter; then I with a syringe injected much *Ægyptiacum* dissolved in wine, and a little *aqua vitæ* into these incisions, so to restrain and amend the putrefaction, repress the spongie, loose and soft flesh, resolve the œdematous and flatulent tumor, asswage the pain, and stir up and strengthen the native heat almost oppress by the abundance of excrementitious humors, so that it could scarcely assimilate any nourishment and adjoin it to the parts. Then I fomented the affected part with Sage, Rose-mary, Time, Lavander, Chamomile and Melilot flowers and Red-rose leaves boyled in white wine, and lye made of Oake-ashes, adding thereto as much salt and vinegar as I judged requisite. This fomentation did attenuate & draw forth the morbid humor. Now we used them long & often, so to waite the humor more by drying up and breathing thorow the passages of the skin, more thereof than fell into the part. For this same purpose, we ordained that he should use frictions with hot linnen clothes, and that these should be made from above downwards, from below upwards, and so on every side, and somewhat long withall: For a short friction drawes more humor into the part than it can resolve: I wished that each other day they should lay bricks heated hot in the fire about his leg, thigh, & soal of his foot; but they were to be somewhat quenched, and sprinkled with wine and vinegar, with a small quantity of *aqua vitæ*. Much watrish moisture by this moist heat, did sweat out of these parts, the tumor was lessened, and the native heat by little and little restored. Then stoups dipped in lye made of Oake-ashes, wherein Sage, Rosemary, Lavander, salt, and cloves, were boyled, some *aqua vitæ* added, were applied thereto; but the rowlers were so gently, and artificially wrapped about, that he did easily endure them without any pain, and that with such happy success, that if they were omitted but for one day, the tumor became very great. But thick linnen boulders were laid upon the lower cavities of the ulcers; that so the *sanies* or filth might be more easily pressed forth: But I had alwayes a speciall care that the orifices of the ulcers should be kept open with hollow Tents or pipes put therein: and sometimes this following cataplasim was applied to resolve the tumor. *R. Far. hord. fabar. & orobi, an. ℥vj. mel. lis com. & tereb. an. ℥ij. flo. cham. em. melil. & ros. rub. an. ℥ss. pulv. rad. Ireos, Flor. cyper. Mast. an. ℥iij. oxymel. simp. quantum sufficit; fiat cataplasma ad formam pultis satis liquida.* And *emplastrum de Vigo* without Mercury was applied thereto, whereby the pain was much asswaged, and the tumor lessened: yet were they not applied before the parts were thoroughly heated by the fomentation, frictions, and evaporations; for

otherwayes this Emplaster could never have been activated, by reason of the excessive coldness of the affected parts. Neither did we omit catapmatick powders, for the taking, & drawing forth of broken bones. He used a vulnerary potion for 15 dayes. Also besides the particular frictions of the affected parts, I appointed other generall frictions of the whole body, which was become very lean; for by these, blood together with the spirit was drawn to the parts, and the acrid, and fuliginous vapours were breathed forth. To conclude, his feaver and pains being asswaged, his appetite restored, by feeding plentifully upon good meats according to his strength, he in a short time became more lusty; and lastly by the singular mercy of God, recovered his health perfectly, but that he could not very well bend his knee. I thought good to recite these things, not to glory or brag, of the happy successe of those Patients, which have recovered by my means, and the favour of God; but that thus I may more fully and perfectly by familiar examples instruct young practitioners, in the operations of Chirurgery.

CHAP. [XIII]. *An Apologie concerning wounds made by Gunshot.*

The occasion of writing this Apologie.

Here lately came to my hands a book written by a certain Physitian, whereby he endeavours to disprove and overthrow, that which I have hitherto writ, of the cure of wounds made by Gunshot. Assuredly if there were no other harm, but the loss of my credit ensuing thereon, I would willingly hold my peace, and stop his mouth by modest silence. But seeing the safety of so many men, lyes upon the judgement of this point, I have thought good to withstand this error, lest it, to the great destruction of mankind, spread and diffuse it self any further.

The chief heads of our adversaries Treatise.

The use (saith he) of suppurative medicins, have killed many who have been but lightly wounded with Gunshot, but acrid medicins, as *Ægyptiacum*, have killed more. Neither is the counsell of *Hippocrates* to be observed in curing this sort of wounds, who bids that every contused wound be brought to suppuration. For seeing this is a new kind of wound, it requires new, and not anciently used medicins. Now the temper of the air changed from the naturall constitution ought not to indicate change of medicins; but much lesse must thunder, and lightning be compared to the shooting of Great Ordinance. These are the chief heads of this his book, which because they dissent from the truth, and these things I have formerly delivered, I have thought good here to confute. First, seeing Leaden Bullets which are usually shot out of Guns are round, obtuse and weighty, they cannot wound the body without contusion and attrition; Now no contusion can be cured without suppuration, not only according to the opinion of *Hippocrates*, but also of *Galen* and all others who have written of Physick. Neither must we invent new remedies, for these new kinds of wounds; for the lawes of the sacred and divine Art of Physick are not obnoxious to change, nor subject to the humor of men or times, as the decrees of Kings and Emperours are. For these are stablished with immutable necessity, which constancy neither consuming time, nor age, nor tyranny can pervert. Wherefore neither these who with great praise are Physitians to Kings and Princes, I mean *Iouber* and *Potallus*, think it lawfull for them to depart from the rules of *Hippocrates*. And this they not only do and follow in curing and doing the works of Art, but much and highly commend, confirm and propound to be diligently observed by all, in their books which they have published concerning the cure of these kinds of wounds. And yet these Physitians are such, as dayly conversant in Armies and Kings houses have healed and dayly cure as many wounded by Gunshot as this Physitian our Antagonist hath seen in all his life. Neither only do these whom I have named thus cure these wounds, but almost all that dresse such kind of wounds do the like, so that if there be nothing which may hinder, or indicate to the contrary, they presently apply suppuratives.

All wounds made by Gunshot are contused.

And I wonder that he hath not observed how his neighbour *Doublet* the Emperick cures desperate wounds of this nature, with no other than a suppurative medicine, composed of Lard, the yolk of an Egge, Turpentine and a little Saffron. In the year 1538. there was at *Turin* whilest I was Chirurgeon there to the Marshall of *Montejan* the Kings Lieutenant Generall in *Piemont* a certain Chirurgeon wondrous famous for curing these wounds, and yet he used nothing else but the oil of Whelpes, (the description whereof I at length obtained of him with much intreaty and expence) and he used it not scalding hot, as some have imagined, but powred it scarce warm into their wounds, and so did mitigate their pain, and happily bring them to suppuration. Which afterwards almost all Chirurgeons, after they had got the description hereof, when I first published this Work, have used and daily doe use with happy successe.

A suppurative medicine of tried efficacy.

The force of *Ægyptiacum* against putrefaction.

But in contemning and condemning *Ægyptiacum*, I think he hath no partaker; seeing there as yet hath been found no medicine more speedy and powerfull to hinder putrefaction, if beginning; or correct it, if present. Now these wounds often degenerate into virulent, eating, spreading, and maligne ulcers, which cast forth a stinking and carion-like filth, whence the part gangrenates, unless you withstand them with *Ægyptiacum* and other acrid medicins, being greatly approved by the formerly named Physitians and all Chirurgeons. But (saith he) this unguent is poysonous, and therefore hath been the death of many who have been wounded by Gunshot. Verily if any diligently enquire into the composition of this ointment, and consider the nature of all and every the ingredients thereof, he shall understand that this kind of Unguent is so far from poyson, that on the contrary it directly opposes and resists all poyson and putrefaction which may happen to a fleshy part, through occasion of any wound.

The force of the air in breeding and augmenting diseases.

It is most false and dissonant from the doctrine of *Hippocrates* to affirm, that the seasons of the year swerving from the Law of nature, and the air, not truly the simple and elementary, but that which is defiled and polluted by the various mixture of putrid and pestilent vapours, either raised from the earth, or sent from above, make not wounds more malign and hard to cure at some times than they are at othersome. For the air eithtr very hot, or cold, drawn into the body by inspiration or transpiration, generates a condition in us like its qualities. Therefore why may it not, when defiled with

the putredinous vapours, of bodies lying unburied after great battails, and shipwracks of great Armadoes, infect with the like quality our bodies and wounds?

In the year 1562. when the civill wars concerning Religion first begun in France, at Pene a Castle lying upon the River *Lot*, many slain bodies were cast into a Well, some hundred cubits deep, so stinking and pestilent a vapour arose from hence some two months after, that many thousand of people dyed all over the Province of *Aginois*, as if the Plague had been amongst them, the pernicious contagion being spread twenty miles in compass; which none ought to think strange, especially seeing the the putrid exhalations by the force of the winds may be driven and carried into divers and most remote regions, dispersed like the seeds of the Pestilence; whence proceeds a deadly corruption of the spirits, humors, and wounds, not to be attributed to the proper malignity, or perverse cure of wounds, but to be the fault of the air. Therefore *Francis Dalechampe* in his *French Chirurgery*, in reckoning up these things which hinder the healing of Ulcers, hath not omitted that common cause which proceeds from the air defiled or tainted with the seeds of the pestilence. For he had learnt from his Master *Hippocrates* that the mutations of times chiefly bring diseases, and he had read in *Guido*, that this was the chief occasion, that wounds of the head at *Paris*, and of the legs at *Avignon*, were more difficultly healed. Lastly, even Barbers and such as have least skill in Chirurgery know, that wounds easily turn into a Gangrene in hot and moist constitutions of the air. Wherefore when the wind is southerly, the Butchers will kill no more flesh than to serve them for one day. I have formerly declared the malignity of the wounds occasioned by the air in the siege of *Roven*, which spared none, no not the Princes of the blood, who had all things which were requisite for their health. Which caused me, made at length more skilfull by experience, to use *Vnguentum Aegyptiacum* and medicins of the like faculty in stead of suppuratives, to wounds during all that season, that so I might withstand the putrefaction and Gangrene which so commonly assailed them. But if the various motion of the stars, can by their influx send a Plague into the air, why then may it not by depravation of their qualities infect, and as by poysoning corrupt both wounds and wounded bodies obnoxious to their changes and that of the air? We learnt long since by experience, that all pains but principally of wounds, grow worse in a rainy and moist season, specially because in that southerly constitution the air replete with thick and foggy vapours, causes the humors to abound in the body, which forthwith easily fall upon the affected parts, and cause increase of pain. But saith our Adversary, in the battell at *Dreux*, and at *S. Dennis* which were fought in winter, there dyed a great number of men who were wounded by Gunshot: This I confess is true; but this I deny, that it was occasioned by applying suppuratives; or corrosives, but rather by the vehemency and largeness of their wounds, & the spoil the bullet made in their members, but above all by reason of the cold. For cold is most hurtfull to wounds and ulcers, (as *Hippocrates* testifies) it hardens the skin and causes a Gangrene. If this my Gentleman had been with me in the siege of *Metz*, he might have seen the Legs of many souldiers to have rotted, and presently taken with a Gangrene to have fallen away, by the only extremity of cold; if he will not beleve me, let him make tryall himself; and go in winter to the Chappell at Mount *Senis* one of the Alpine hills, where the bodies of such as were frozen to death in passing that way are buried, and he shall learn and feel how true I speak. In the meantime I think it fit to confute the last point of his reprehension.

He cavills for that I compared Thunder and Lightning with the discharging peeces of Ordnance. First he cannot deny but that they are alike in effects. For it is certain that the flame arising from Gunpowder set on fire, resembles Lightning; in this also that you may see it before you hear the crack or report. I judg for that the eye almost in a moment perceives its objects; but the ear cannot but in some certain space of time, and by distinct gradations. But the rumbling noise is like in both, and certainly the report of great Ordnance may be heard sometimes at forty miles distance, whilst they make any great battery in the besieging of Cities. Besides also, Iron Bullets cast forth with incredible celerity by the fired Gunpowder, throw down all things with a horrid force, and that more speedily and violently by how much they resist the more powerfully by their hardness. They report that Lightning melts the money not hurting the purse; Now many by the only violence of the air agitated and vehemently moved by shooting a peece of Ordnance, as touched with Lightning have dyed in a moment, their bones being shivered and broken, no sign of hurt appearing in the skin. The smell of Gunpowder when it is fired, is hurtfull, fiery and sulphurous, just like that which exhales or comes from bodies killed with Lightning. For men do not only shun this smell, but also wild Beasts leave their Dens if touched with Lightnings. Now the cruelty of great Ordnance makes no less spoil amongst buildings, nor slaughter amongst men and beasts, than Lightnings do, as we have formerly shown by examples, not only horrid to see, but even to hear reported, as of Mines, the Arcenall of *Paris*, the City of *Malignes*. These may seem sufficient to teach, that thunder and lightning have a great similitude with the shooting of great Ordnance, which notwithstanding I would not have a like in all things. For they neither agree in substance, nor matter, but only in the manner of violent breaking asunder the objects.

Now let us see and examin what manner of cure of wounds made by Gunshot our adversary substitutes for ours. For he would have suppuratives used and applyed, yet such as should not be hot & moist in quality, or of an Emplastick consistence, but hot and dry things. For (saith he) here is not the same reason as in Abscesses, where the Physitian intends nothing but suppuration. But here because a contusion is present with the wound, this requires to be ripened with suppuratives, but the wound to be dried.

Now to answer this objection, I will refer him to *Galen*, who will teach him the nature of suppuratives; from whom also he may learn that great regard is to be had of the cause and more urgent order in the cure of compound diseases; then would I willingly learn of him, whether he can heal a wound made by Gunshot, not first bringing that which is contused to perfect maturity. If he affirm he can, I

will be judged by whatsoever Practitioners he will, to judg how obscure these things are. Whereby you may the better understand there is nothing more commodious than our *Basilicon* and oil of Whelps to ripen wounds made by Gunshot, if so be that putrefaction, corruption, a Gangrene or some other thing do not hinder. Then would he have *Oxycrate* poured into these wounds to stay their bleeding; which if it cannot so be stayed, he would have a medicin applyed consisting of the white of an Egge, Bole Armenick, oil of Roses and salt. But I leave it to other mens judgment, whether these medicins have power to stay bleeding if put into the wound; certainly they will make it bleed the more. For vinegar seeing it is of a tenuious substance and biting, it is no doubt but that it will cause pain, defluxion and inflammation. To which purpose I remember I put to stanch bleeding, for want of another remedic, a medicin wherein was some Vinegar, into a wound received by a Moor, an attendant of the Earl of Roissy, hurt with a Lance, run through his arm before *Bologne* by an *English* horseman. But he comes again to me a little after, complaining and crying out that all his arm burnt like fire; wherefore I was glad to dress him again, and put another medicin into his wound, and laid an astringent medicin upon the wound, but poured it not therein. And then above all other remedies he extols his Balsam composed of oil of Wax, and Myrrh beaten together with the white of an Egge; which he saith is equall in operation to the naturall Balsam of *Peru*. For he affirms that this hath a faculty to consume the excrementitious humidity of wounds, and so strengthens the part that no symptom afterwards troubles them. Yet he saith, this doth not so well heal and agglutinate these wounds, as it doth others which are cut. Verily it is ridiculous to think that contused wounds can be healed after the same manner as simple wounds may, which only require the uniting of the loosed continuity.

Vinegar
put into a
wound doth
not stay but
causes bleed-
ing.
A History.

Balsams are
fit to heal
simple but
not contu-
sed wounds.

Therefore neither can these Balsams be fit remedies to heal wounds made by Gunshot, seeing by reason of their dryness they hinder suppuration, which unless it be procured the Patient cannot be healed. Wherefore such things ought not be put into wounds of this nature, before they be ripened, washed and censed from their filth. Yet can I scarce conceive, where we shall be able to find out so many Chymists which may furnish us with these things sufficiently to dress so many wounded souldiers as usually are in an Army, or whence the souldiers have sufficient means to bear the charge thereof. Also that which he saith is absurd, that these Balsams must be put into the wounds without Tents; and presently forgetting himself, he saith, it will not be amiss, if there be a little and slender Tent put into the wound, which may only serve to hinder the agglutination thereof. But how can these Balsams come to the bottomes of wounds without Tents, when as it is their chief property to carry medicins even to the innermost parts of the wounds, and alwayes keep open a free passage for the evacuation of the quittance? But it is not worthy, that after he hath rejected *unguentum Aegyptiacum*, he nevertheless bids to apply it, from the beginning untill the contusion come to perfect maturation, dissolving it in a decoction of the tops of wormwood, *S. Iohn Wurt*, the lesser Centory and Plantain, and so injecting it into the wound. Besides also a little after he gives another way of using it, which is, to boil a quantity of Hony of Roses in plantain water, carefully skimming it, untill it be boiled to the consistence of Hony, and then to add as much *Aegyptiacum* thereto, and so to make an ointment most fit to bring these wounds to suppuration. But I leave it for any skilful in Chirurgery to judg, whether such medicins can be suppuratives, or whether they be not rather deterstives. Last of all he writes, that these wounds must be dressed but every fourth day. And if there be a fracture of the bone joyed with the wound, then to move nothing after the first dressing untill the eighth day after; then presently in another place he saith, it will be good, and expedient, to drop ten or twelve drops of the formerly described Balsam every day into the wound. Verily such doctrine which neither agrees with its self nor the truth, cannot but much puzzle a Novice and young Practitioner in Chirurgery, who is not yet in versed the Art, or the operations thereof.

Aegyptiacum
howsoever
made is a
censer, not a
suppurative.

CHAP. XIII. Another Apologie, against those who have laboured with new reasons to prove that wounds made by Gunshot are poysoned.

The occasi-
on of this
Apology.

Some few months ago, I visited a Patient together with some learned Physitians and skilfull Chirurgeons. Now they, as it oft-times happens, in way of discourse, begun to argue of the condition & quality of wounds made by Gunshot; & indeavoured to prove that they might be poysoned by five reasons. Not truly through the occasion of the Gunpouder, for they all confessed that it was free from poyson, whether you have regard to its essence, or to its composition; but by the Bullet, into which the poyson may be transfused and incorporated. The first reason is, that Lead seeing it is of a rare and spongius nature, which the easiness of melting and softness argues, is very fit to drink and soak in what liquors so ever you please. But me thinks this conclusion is very weak; for in all mixtures made by Art, such as this is whereof we speak, there are two things to be considered; that is to say, the matter of the things which enter into the mixture, and the form: for the matter, such bodies must be either liquid, or soft, or friable; and lastly such as may be broken and divided into small particles, that so they may easily in all parts concur and be conjoynd and united. But for their form, there ought to be a certain affinity, consent and sympathy. You may perceive this by water and oil; for each of them though of a liquid substance, and such as may easily be mixed with divers other things, yet cannot they be mixed the one with the other by reason of their antipathy of forms. For thus gold and silver are so agreeing with lead, that as oft as they are molten lead is mixed with them. But brass shuns lead as much as gold and silver fly tin and white lead. If therefore brass and lead being melted cannot be mixed together, though contained under the same *Genus*, and common nature of Metals; how then can it be commixt with another thing distinct in the whole kind, much more in *species*, and form, to wit, poyson? Their second reason is this; Iron, say they, which is more dense,

The reason
of our ad-
versaries
that the Bul-
lets may be
poysoned,
set down
and confu-
led.

dense, solid, and less porous, may receive some venenate substance and quality, as the Arrows of the Ancients which were dipped in poyson, testifie; therefore must Lead much more be capable thereof. I answer, that the surface of Iron may be poysoned, but not the inner part or substance by mixture therewith. But here the question is of union, but not of anointing or inunction. The third reason is thus framed; though (say they) lead cast off and purges it self from the dross and unpure parts, yet that is no argument that it will not commix, or soak it self in some strange liquor or body; for thus Steel, being the most solid Iron, receives the temper which hardens it by the artificial pouring upon it or quenching it in liquors contrary thereto in their whole kind. I answer, that Steel admits into it by that quenching and tempering, none of the juyces or liquors wherewith it is watered or quenched. For if that were necessary, it might be better & more easily performed, when the metall is first cast, than when it is beaten into plates or bars; which answer shal serve to confute their fourth reason; wherin they say, that bullets may be made so poysonous by the commixture of the juyces of [Muncks-hood, Oleander, Crow-foot, and other such like things which in their whole substance are contrary to ours, that the wound which is made with them cannot but be poysoned. But I on the contrary affirm, that mixture is only of these things, which may not only be put, but also stick thereto, & be mutually united but how can water or any other liquid juice so much as only stick to lead, as that which is a solid & firm body, it is so far from being united, therewith? You may give more certain judgment hereof by experience, than by reason; wherefore let melted lead be put into the foresaid juyces or the like; then when the lead is cold, weigh each of them severally and you shal find, that both of them retain the same weight they formerly had. Which is a most certain argument that neither the lead hath mixed or united it self with the juyces, nor the juyces lost any part of their substance. Their fifth reason is thus; A bullet shot out of a Gun against some hard stone, grows not so hot, but that you may presently without any harm take it up in your hand. Therefore it is false, that the poyson commixt & united with the bullet can be dissipated by the fire and flash of Gunpowder. The answer to this objection is easie. For when we say, that although the Bullet may be infected by poyson perfectly commixt with the lead, yet all the force of the poyson would be dissipated by the fire, we would have you thus to understand us, that we do not mean this of that fire which is made by the powder at the discharging of the Peice, but of that by force whereof the molten lead is mixed and conjoined with the venenate juice, so to make one of many. For this fire exercising its force upon the venenate juyces hindered by the intercourse of no *Medium*, and that for some space of time, and not for an instant, it may, if not consume, yet much weaken their strength. If there be any, who will not be satisfied by these reasons, let him consult, & read *Mathiolus*. There are (saith he) some of these later times wholly ignorant of things, who (if we may say the truth) have been so madly foolish, that they said it was fit and requisite to put Treacle and Mithridate and such like antidotes amongst gold and silver that was melted to make cups, that so receiving the faculties of the Antidote they might resist poyson. But how absurd and ridiculous their opinion is, let them judg (for it needs no clearer reproof) who have but a little knowledg in naturall things, but chiefly in metallis. These are my reasons, these the authorities of men excelling in learning & judgment, that confirm me in my ancient & former opinion, that wounds made by Gunshot do not partake of any venenate quality.

In praesentibus
6 Diascor.

CHAP. XV. How wounds made by Arrows differ from such as are made by Gunshot.

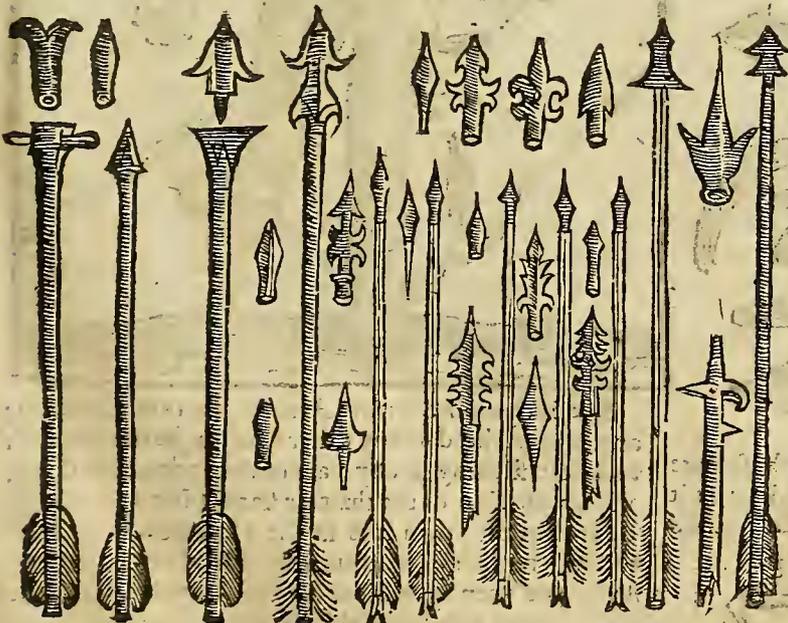

Wounds made by arrows and bolts shot out of Cross-bows and such like things, differ chiefly in two things, from these which are made by gunshot. The first is, for that they are oft-times without contusion, which the other never are. The other is, for that they oft-times are poysoned. In both these respects, their cure is different from the other. But the cure of these wounds made by arrows is different in it self, by reason of the variety and divers sorts of Darts or Arrows.

Wounds made with Arrows and such like things, are often without our contusion. But are oft-times poysoned. The differences of Arrows.

The figure of divers sorts of Arrows.

CHAP. XVI. Of the diversities of Arrows and Darts.

Arrows and Darts are different amongst themselves both in matter and in form or figure, in number, making, faculty or strength; In matter, for that some of them are of wood, some of reeds, some are blunt headed, others have piles or heads of iron, brass, lead, tin, horn, glasse, bone. In figure, for that some are round, others cornered, some are sharpe pointed, some barbed, with the barbs standing either to the point, or shafts, or else acrosse, or both wayes, but some are broad and cut like a Chissell. For their bignesse, some are three foot long, some lesse. For their number, they differ in that, because some have one head, others more. But they vary in making; for that some of them have

In matter;

In signa.

In bignesse.

In number.

In making;

In force. have the shaft put into the head, others the head into the shaft; some have their heads nailed to the shaft, others not, but have their heads so loosely set on, that by gentle plucking the shaft, they leave their heads behind them, whence dangerous wounds proceed. But they differ in force, for that some hurt by their Iron only, others besides that, by poyson, wherewith they are infected. You may see the other various shapés represented to you in the preceding Figure.

CHAP. XVII. *Of the difference of the wounded parts.*

You must not leave the weapon in the wound.

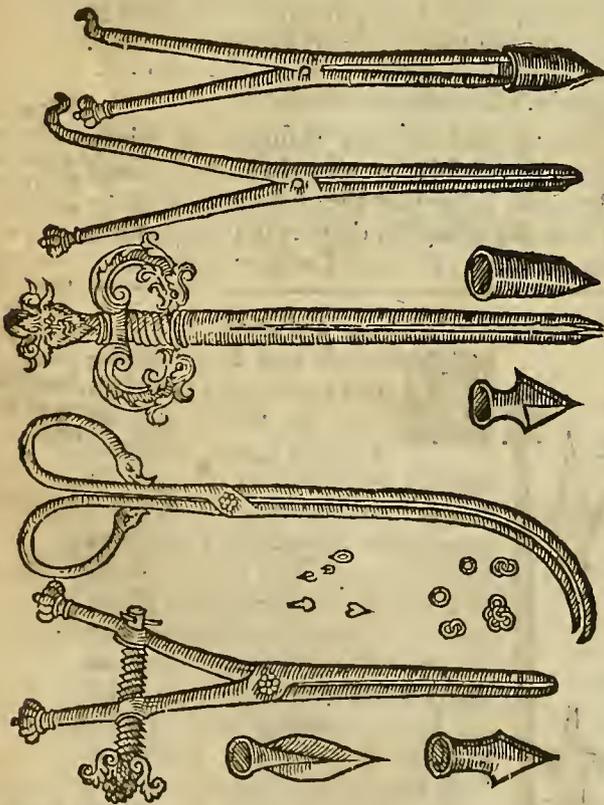

The wounded parts are either fleshy or bony; some are neer the joints, others seated upon the very joints; some are principall, others serve them; some are externall, others internall. Now in wounds where deadly signs appear, it's fit you give an absolute judgment to that effect; lest you make the Art to be scandalled by the ignorant. But it is an inhumane part, and much digressing from Art, to leave the Iron in the wound; it is sometimes difficult to take it out, yet a charitable and artificiall work. For it is much better to try a doubtfull remedy, than none at all.

CHAP. XVIII. *Of drawing forth Arrows.*

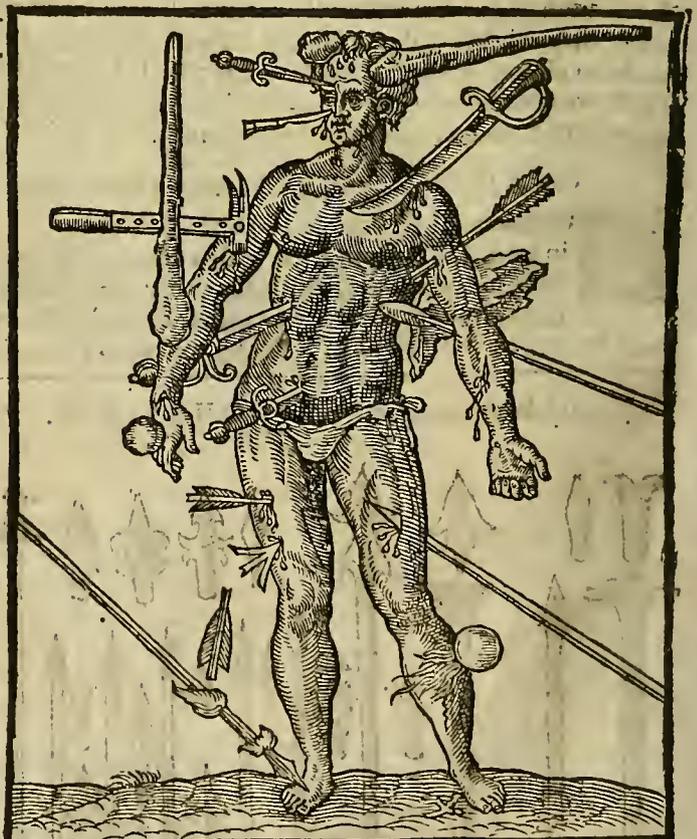

The manner of drawing forth Arrows, and such weapons.

You must in drawing forth Arrows shun incisions and dilacerations of Veins and Arteries, Nerves and Tendons. For it is a shamefull and bungling part to do more harm with your hand, than the Iron hath done. Now Arrows are drawn forth two wayes, that is, either by extraction, or impulsion. Now you must presently at the first dressing pull forth all strange bodies, which that you may more easily and happily perform, you shall set the Patient in the same posture, as he stood when he received his wound; and he must have also his Instruments in a readinesse, chiefly that which hath a slit pipe and toothed without, into which there is put a sharpe Iron style, like the Gimblets we formerly mentioned for the taking forth of Bullets; but that it hath no scrue at the end, but is larger and thicker, so to widen the pipe, that so widened it may fill up the hole of the Arrows head whereinto the shaft was put, and so bring it forth with it, both out of the fleshy as also out of the bony parts, if so be that the end of the shaft be not broken, and left in the hole of the head. That also is a fit Instrument for this purpose, which opens the other end toothed on the outside, by pressing together of the handle. You shall find the Iron or head that lies hid by these signs, there will be a certain roughnesse and inequality observable on that part if you feel it up and down with your hand; the flesh there will be bruised, livid, or black, and there is heavinesse and pain felt by the Patient both there and in the wound.

A delineation of Instruments fit to draw forth the heads of arrows, & darts, which are left in the wound without their shafts.

A hooked Instrument fit for to draw forth strange bodies, as pieces of Male, and such other things as it can catch hold of, which may also be used in wounds made by Gunshot.

But if by chance either Arrows, Darts or Lances, or any winged head of any other weapon, be run through and left sticking in any part of the body, as the thigh, with a portion of the shaft or staffe slivered in pieces, or broken off; then it is fit the Chirurgion with his cutting mullets should cut off the end of the staffe or shaft, and then with his other mullets pluck forth the head, as you may see by this Figure.

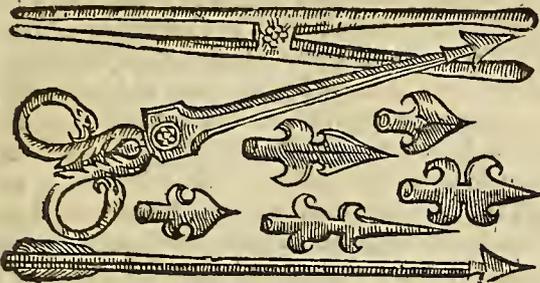

CHAP. XIX. How Arrows broken in a wound may be drawn forth.

Ut if it chance that the weapon is so broken in the wound, that it cannot be taken hold on by the formerly mentioned Mullets, then must you draw, or pluck it out with your Crane; or Crows bill, and other formerly described Instruments: But if the shaft be broken near the head, so that you cannot take hold thereof with your Cranes bill, then you shall draw it forth with your Gimblet which we described before to draw forth bullets; for if such a Gimblet can be fastned in bullets, it may far better take hold of wood. But if the head be barbed, as usually the English arrows are, then if it may be conveniently done, it will be very fitting to thrust them through the parts. For if they should be drawn out the same way they went in, there would be no small danger of breaking or tearing the Vessells and Nerves by these hooked barbes. Wherefore it is better to make a section on the other side whither the head tended, and so give it passage forth if it may be easily done; for so the wound will be the more easily clenfed and consolidated. But on the contrary, if the point tend to any bone, or have many muscles or thick flesh against the head thereof, as it happens sometimes in

VWhen to draw forth the weapon on the contrary side

A Dilater hollowed on the inside, with a Cranes-bill to take hold of the barbed head.

the Thighs, Legs and Armes; then you must not thrust the head through, but rather draw it out the same way it came in, dilating the wound with fit Instruments, and by skill in Anatomic. shunning the larger Nerves and Vessells. Therefore for this purpose put a hollow Dilater into the wound, and therewith take hold of both the barbs or wings of the head; and then take fast hold of the head with your Cranes-bill, and so draw them forth all three together.

VWhen by the same way it went

CHAP. XX. What to be done, when an Arrow is left fastned or sticking in a bone.

Ut if the weapon be so depect and fastned in a bone that you cannot drive it forth on the other side, neither get it forth by any other way than that it entred in by; you must first gently move it up and down, if it stick very fast in, but have a special care that you do not break it, & so leave some fragment thereof in the bone; then take it forth with your Crows bill, or some other fit Instrument formerly described. Then press forth the blood, and suffer it to bleed somewhat largely, yet according to the strength of the Patient and nature of the wounded part. For thus the part shall be eased of the fulness and illness of humors, and less molested with inflammation, putrefaction and other symptomes which are customarily feared. When the weapon is drawn forth, and the wound once dressed, handle it, if simple, as you do simple wounds; if compound, then according to the condition and manner of the complication of the effects; Certainly the Oil of Whelpes formerly described is very good to assuage pain. To conclude, you shall cure the rest of the Symptomes according to the method prescribed in our Treatise of wounds in generall, and to that we have formerly delivered concerning wounds made by Gunshot.

A Caution. The benefit of bleeding in wounds.

CHAP. XXI. Of poysoned wounds.

These wounds at any time prove poysoned, they have it from their primitive cause, to wit, the empoisoned Arrows, or Darts of their enemies. You may find it out both by the property of the pain, if that it be great and pricking, as if continually stung with Bees, for such pain usually ensues in wounds poysoned with hot poyson, as Arrows usually are; Also you shall know it by the condition of the wounded flesh; for it will become pale and grow livid, with some signs of mortification. To conclude, there happen many and malign symptomes upon wounds which are empoisoned, being such as happen not in the common nature of usuall wounds. Therefore presently after you have plucked forth the strange bodies, encompass the wound with many and deep scarifications, apply ventoses with much flame, that so the poyson may be more powerfully drawn forth; to which purpose the sucking of the wound, performed by one whose mouth hath no soariness therein, but is filled with oil, that so the poison which he sucks may not stick, nor adhere to the part, will much conduce. Lastly, it must be drawn forth by rubefying, vesicatory and caustick medicines, and assailed by ointments, cataplasmes, emplasters, and all sorts of locall medicins.

The signs of poysoned wounds.

Remedies in poysoned wounds.

The end of the Eleventh Book.

Of Contusions and Gangrenes.

THE TWELFTH BOOK.

CHAP. I.

Gal. Lib. de
artis consti-
tuti.
Sect. 2. lib.
de fracturis.
Causes of
Bruises and
Sugillati-
ons.

Contusion according to *Galen*, is a solution of continuity in the flesh or bone, caused by the stroak of some heavy and obtuse thing, or a fall from an high. The symptome of this disease is by *Hippocrates* called *Peliosis*, and *Melasma*, that is to say, blackness and blewness; the Latins term it *Sugillatum*. There are divers sorts of these Sugillations or blacknesses, according as the blood is poured forth into the more inward or outward part of the body. The blood is poured forth into the body, when any (for example) falls from an high, or hath any heavy weight falls upon him, as it often happens to such as work in Mines, or are extremely racked or tortured; and sometimes by too loud and forcible exclamation. Besides also by a Bullet shot through the body, blood is poured forth into the bellie, and so often evacuated by the passages of the Guts and bladder. The same may happen by the more violent and obtuse blowes of a hard Trunchion, Club, Stone, and all things which may bruise and press the blood out of the vessells either by extending or breaking them. For which causes also the exterior parts are contused, or bruised sometimes with a wound, sometimes without, so that the skin being whole, and as far as one can discern, untoucht, the blood poures it self forth into the empty spaces of the muscles, and between the skin and muscles; which affect the Ancients have tearmed *Echymosis*; *Hippocrates* calls it by a peculiar name *Nausiosis*, for that in this affect the swoln veins seem as it were to vomit, and verily do vomit or cast forth the superfluous blood which is contained in them. From these differences of Contusions are drawn the indications of curing, as shall appear by the ensuing discourse.

Sect. 2. lib.
de fract.

CHAP. II. Of the generall cure of great and enormous Contusions.

The blood poured forth into the body, must be evacuated by visible and not visible evacuation. The visible evacuation may be performed by blood-letting, Cupping-glasses, horns, scarification, horseleeches and fit purgative medicins; if so be the Patient have not a strong and continuall fever; The not visible evacuation is performed by resolving and sudorifick potions, baths, and a slender diet. Concerning Blood-letting *Galen*'s opinion is plain, where he bids, in a fall from an high place, and generally for bruises upon what part soever they be, to open a vein, though the parties affected are not of a full constitution; for that unless you draw blood by opening a vein, there may inflammations arise from the concreat blood, from whence without doubt evill accidents may ensue. After you have drawn blood give him foure ounces of Oxycrate to drink; for that by the tenuity of its substance hinders the coagulation of the blood in the belly, or in stead thereof you may use this following potion. *Rx rad. Gentiane* \mathfrak{z} iiij. bulliant in Oxycrato; in colatura dissolve *rhei electi* \mathfrak{z} j. fiat potio. These Medicins dissolve, and cast forth by spitting and vomit the congealed blood, if any thereof be contained in the ventricle or lungs; it will be expedient to wrap the Patient presently in a sheeps skin, being hot and newly taken from the sheep, and sprinkled over with a little myrrhe, cresses and salt, and so to put him presently in his bed, & then cover him so that he may sweat plentifully. The next day take away the sheeps-skin, and anoint the body with the following anodyne and resolving unguent. *Rx unguent. de althæa* \mathfrak{z} vj. olei *Lumbric. chamem. anethi. an.* \mathfrak{z} ij. *terebinth. venetæ* \mathfrak{z} iiij. *farinæ fœnuigræ. rosar. rub. pulverisat. pul. myrtillorum, an.* \mathfrak{z} j. fiat litus ut dictum est. Then give this potion which is sudorifick and dissolves the congealed blood. *Rx Ligni guajaci* \mathfrak{z} viii. *radicis enulæ camp. consolid. majoris, ireos Florent. polypod. querni, seminis coriandri, anisi, an.* \mathfrak{z} β. *glycyrrhiz. zij. nepetæ, centaureæ, caryophyl. cardui ben. verbenæ, an. m. s. aquæ fontanæ lib. xij.* Let them be all beaten and infused for the space of twelve houres, then let them boil over a gentle fire untill the one half be consumed; let the Patient drink some half pint of this drink in the morning, and then sweat some hour upon it in his bed, and doe this for seaven or eight dayes. If any poor man light upon such a mischance, who for want of means cannot be at such cost, it will be good, having wrapped him in a sheet, to bury him up to the chin in Dung mixed with some hay or straw, and there to keep him, untill he have sweat sufficiently. I have done thus to many with very good success. You shall also give the Patient potions made with syrups which have power to hinder the coagulation and putrefaction of the blood; such as syrup of Vinegar, or Lemons, of the juice of Citrons and such others to the quantitie of an ounce dissolved in scabius, or *Carduus* water. You may also presently after the fall give this drink, which hath power to hinder the coagulation of the blood, and strengthen the bowells. *Rx Rhei electi. in pul. redacti* \mathfrak{z} j. *aque rubiæ majoris, & plantagin. an.* \mathfrak{z} j. *theriacæ* \mathfrak{z} β. *syrupi de rosis siccis, zβ. fiat potus.* Let him take it in the morning for foure or five dayes. In stead hereof you may make a potion of one dram of *Sperma ceti* dissolved in bugloss or some other of the waters formerly mentioned, and half an ounce of syrup of Maiden-hair; if the disease yeeld not at all to these formerly prescribed medicins, it will be good to give the Patient for nine dayes, three or foure houres before meat some of the following powder. *Rx rhei torrefacti, rad. rub. majoris, centaurei, gentianæ, aristolo. rotundæ, an.* \mathfrak{z} β. give \mathfrak{z} j. hereof with syrup of Vinegar and *Carduus* water. They say that the water of green Walnuts, distilled by an Alembick, is good to dissolve congealed and knotted blood. Also you may use baths made of the decoction of the roots of Orris, Elecampane, Sorrell, Fennell, Marshmallows, Water-fern, or Of-

mund the waterman, the greater Comfrey, the seeds of Fænugreek, the leaves of Sage, Marjerum; the flowres of Camomile, Melilote, and the like. For a warm bath hath power to rarifie the skin, to dissolve the clotted blood, by cutting the tough and mitigating the acrid humors, by calling them forth into the surface of the body, and relaxing the passages thereof; so that the rebellious qualities being overcome, there insues an easie evacuation of the matter by vomit, or expectoration, if it stote in the stomach, or be contained in the Chest; but by stool & urin, if it lye in the lower parts; by sweats and transpiration, if it lye next under the skin. Wherefore bathes are good for those who have a *Peripneumonia* or inflammation of their Lungs, or a Plurisie, according to the mind of *Hippocrates*, if so be that they be used, when the feaver begins to be asswaged; for so they mitigate pain, help forwards suppuration, and hasten the spitting up of the purulent matter. But we would not have the Patient enter into the bath, unless he have first used generall remedies, as blood-letting and purging; for otherwise there will be no small danger, lest the humors diffused by the heat of the bath, cause a new defluxion into the parts affected. Wherefore do not thou by any means attempt, to use this or the like remedy, having not first had the advice of a Physitian.

CHAP. III. How we must handle Contusions, when they are joyned with a wound.

EVery great Contusion forthwith requires blood-letting, or purging, or both; and these either for evacuation, or revulsion. For thus *Hippocrates* in a contusion of the heel, gives a vomitory portion, the same day, or else the next day after the heel is broken. And then if the Contusion have a wound associating it, the defluxion must be stayed at the beginning with an ointment made of Bole Armenick, the whites of eggs, and oil of roses, and myrtles, with the pouders of red roses, allome and mastich. At the second dressing apply a digestive made of the yoalk of an eg, oil of violets and turpentine. This following cataplasmi shall be applied to the near parts to help forwards suppuration. *R. rad. alth. ee, & lili, an. ʒ iiij. sol. malv. violar. senecionis, an. M. ss. coquantur complete, & passentur per setaceum, addendo butyri recentis & olei viol. an. ʒ iiij. farinæ volatilis quant. sufficit; fiat cataplasma ad formam pulvis liquida.* Yet have a care in using of Cataplasms, that you do not too much exceed; for too frequent and immoderate use of them makes wounds phlegmionous, fordid and putrid. Wherefore the wound after it is come to suppuration must be clenfed, filled with flesh and cicatrized, unless happily the contused flesh shall be very much torn, so that the native heat forsake it, for then it must be cut away. But if there be any hope to agglutinate it, let it be sowed, and other things performed according to Art; but the stiches must not be made so close together, as when the wound is simple, and without contusion; for such wounds are easily inflamed and swell up, which would occasion either the breaking of the thred or flesh, or tearing of the skin.

be observed.

How contused
wounds
must be
sowed.

CHAP. IV. Of these Contusions which are without a wound.

IF the skin being whole and not hurt, as far as can be discerned, the flesh which lies under it be contused, and the blood poured forth under the skin make an *Ecchymosis*, then the Patient must be governed according to Art untill the malign symptomes which commonly happen, be no more to be feared. Wherefore in the beginning draw blood on the opposite side, both for evacuation and revulsion. The contused part shall be scarified with equall scarificationis; then shall you apply cupping-glasses or horns, both for evacuation of the blood which causes the tumor and tension in the part; as also to ventilate and refrigerate the heat of the part, lest it turn into an Abscesse. Neither must we in the mean while omit gentle purging of the belly. The first topick medicins ought to be astringives, which must lye some short while upon the part, that so the Veins, and Arteries may be as it were straitned and closed up; and so the defluxion hindred; as also that the part it self may be strengthened. This may be the form of such a remedy, *R. Albumina ovorum nu. iij. olei myrtini & rosacei, an. ʒ j. boli armeni, & sanguin. dracon. an. ʒ ʒ. nucium cupres. gallarum, pul. aluminis usti, an. ʒ ij. incorporentur omnia addendo aceti parum, fiat medicamentum.* Then you shall resolve it with a fomentation, cataplasmi and discussing emplasters.

After astringives
must follow discussives.

CHAP. V. By what means the contused part may be freed from the fear and imminent danger of a Gangrene.

Great contusions are dangerous even for this cause, for that a Gangrene and mortification sometimes follows them; which *Hippocrates* teacheth to happen, when as the affected part is grown very hard and liquid. Wherefore when the part grows livid and black, and the native colour thereof, by reason of the efflux of the concreat blood, is almost extinct; chiefly to ease the part of that burden, cupping-glasses and horns shall be applyed to the part it self being first scarified with a Lancet, or else the following Instrument termed a *Scarificator*, which hath 18. little wheels sharp and cutting like a razor, which may be straitned and slacked by the pins noted by *D.* and *P.* This instrument is to be commended for that it performs the operation quickly and gently, for it makes 18 incisions in the space that you make one with a Lancet or knife.

See 2. lib.
de fract.

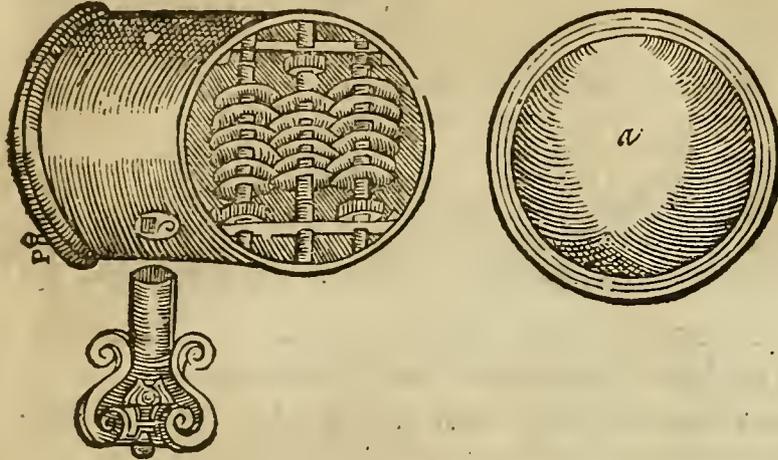

The cause of
a Gangrene.

The use of a
Scarificator.

Then shall you foment the part with strong vinegar wherein the roots of radish or of Dragons; Cuckow-pint, Salemons Seal, *Auripigmentum* and the like have been boiled; for such acrid things do powerfully heat, resolve and draw the concreat blood from the inner part of the body unto the skin, which by its setting in the part affected, prohibits the entrance of the vitall spirits, the preservers of its integrity; yea also extinguisheth the native heat of the same part. Now we must not use these things but with great discretion, lest so we draw not only that blood which is poured forth of the vessels,

but

but also the other which is contained in the vessels. Moreover also we must not use them, unless when the defluxion is stayed. For small contusions (which *Galen* judgeth by the softness of the contused part) it will be sufficient to apply to discusse them, *Virgins* wax dissolved and mixed with *Cumin* seeds, *Cloves*, the root of black *Briony*, (which hath a wonderful faculty to discusse all blacknesses and fugillations:) for the same purpose, you may also apply wormwood bruised and so warmed in a dish and sprinkled over with a little white wine. Also fry wormwood with oil of camomill, bran, the powder of *Cloves*, and *Nutmegs*, adding thereto a little *aqua vite*, then put all in a linnen cloth and apply it hot to the part. The following emplaister doth powerfully discusse congealed blood.

CHAP. VI. Of that strange kind of symptome which happens upon contusions of the ribs.

Hip sect. 3. lib. de art. sent. 58. & 65.

Remedies for a mucous and flatulent tumor of the ribs. The cause.

The flesh contused sometimes by great violence becomes mucous and swollen, or puffed up like Veal, which the butchers blow up, the skin remaining whole. This is seen and happens chiefly in that flesh which is about the ribs; for this being bruised either by a blow, or fall, or renitency, or any other such like cause; if you press it with your hand, a certain windiness goeth out thereof with a small whizzing, which may be heard, and the print of your fingers will remain as in *œdema's*. Unless you quickly make fit provision against this symptome, there is gathered in that space which the flesh departing from the bones, leaves empty, a certain purulent sanies, which divers times fouls and corrupts the ribs. It will be cured, if the mucous tumor be presently pressed, & straitly bound with ligatures, yet so that you hinder not the breathing, when as the affect happens upon the ribs and parts of the Chest. Then apply to the part a plaister of *Oxycroceum* or *diachylon Ireatum* with the emplaister *de meliloto*; also discussing fomentations shall be used. The cause of such a tumor is a certain mucous flegm; seeing that nature is so weak that it cannot well digest the nourishment, and assimilate it to the part, but leaves something as it were half concocted. No otherwise than the conjunctive coat of the eye is sometime so lifted up and swollen by a stroak, that it starts as it were out of the orb of the eye, leaving such filth or matter as we see those which are blear eyed to be troubled withall; because the force and naturall strength of the eyes is become more weak, either by the fault of the proper distemperature, or the abundance of moisture which flows thither, as it happens in those tumors which are against nature. For flatulencies are easily raised from a waterish and phlegmatick humor wrought upon by weak heat, which mixed with the rest of the humor, the tumor becomes higher.

CHAP. VII. A discourse of Mumia, or Mummy.

Mummie a frequent and usuall medicin in contusions. The reason that the Author makes no mention thereof amongst his medicins. The opinion of the Arabians concerning it.

Lib. 4. cap. 84. Another opinion of Mummie.

Eradventure it may seem strange what may be the cause, why in this Treatise of curing contusions, or bruises, I have made no mention of giving Mummy either in bole, or potion to such as have fallen from high places, or have been otherwise bruised; especially seeing it is so common and usual, yea the very first and last medicin of almost all our practitioners at this day in such a case. But seeing I understood, and had learnt from learned Physicians, that in using remedies, the indication must alwayes be taken from that which is contrary to the disease, how could I? how can any other give Mummie in this kind of disease, seeing we cannot as yet know what Mummie is, or what is the nature and essence thereof? So that it cannot certainly be judged; whether it have a certain property contrary to the nature and effects of contusions. This how it may have, I have thought good to relate somewhat at large; neither do the Physicians who prescribe Mummie, nor the Authors that have written of it, nor the Apothecaries that sell it, know any certainty thereof. For if you read the more ancient *Serapio* and *Avicen* or the modern *Matthiolus* and *Thevet*, you shall find quite different opinions. Ask the Merchants who bring it to us, ask the Apothecaries who buy it of them, to sell it to us, and you shall hear them speak diversly hereof, that in such variety of opinions, there is nothing certain and manifest. *Serapio* and *Avicen* have judged Mummie to be nothing else but *Pissasphaltum*; now *Pissasphaltum* is a certain froth or foam rising from the Sea, or Sea waters; this same foam as long as it swims upon the water is soft and in some sort liquid: but being driven upon the shore by force of tempest, and working of the sea, and sticking in the cavities of the rocks, it concreats into somewhat a harder substance than dried pitch, as *Dioscorides* saith. *Belonius* saith, that Mummie is only known to *Egypt* and *Greece*. Others write that it is mans flesh, taken from the carcasses of such as are dead, and covered over in the sands in the deserts of *Arabia*; in which Country they say the Sands are sometimes carried and raised up with such force and violence of the winds, that they overthrow and suffocate such passengers

as they meet withall; the flesh of these dried by the sand and wind they affirm to be Mummie. *Mathiolus* following the more usuall and common opinion writes, that Mummie is nothing else than a liquor flowing from the Aromatick embalmments of dead bodies, which becomes dry and hard. For understanding whereof you must know from all manner of antiquity, that the *Aegyptians* have been most studious in burying and embalming their dead; not for that end that they should become medicins for such as live, for they did not so much as respect or imagin so horrid a wickednes; but either for that they held an opinion of the generall resurrection, or that in these monuments they might have something, whereby they might keep their dead friends in perpetuall remembrance. *Thevet* not much dissenting from his own opinion, writes that the true Mummie is taken from the monuments and stony tombs of the anciently dead in *Egypt*, the chinks of which tombs were closed, and cimented with such diligence; but the inclosed bodies embalmed with pretious spices with such Art for eternity, that the linnen vestures which were wrapt about them presently after their death, may be seen whole even to this day; but the bodies themselves, are so fresh that you would judg them scarce to have been three daies buried. And yet in those Sepulchers and Vaults from whence these bodies are taken, there have been some corps of two thousands years old. The same, or their broken members are brought to *Venice* from *Syria* & *Egypt*, and thence disperst over all *Christendom*. But according to the different condition of men, the matter of their embalmments were divers; for the bodies of the Nobility or Gentry are embalmed with Myrrh, Aloes, Saffron, and other precious spices, and Drugs; but the bodies of the common sort whose poverty and want of means could not undergo such cost, were embalmed with asphaltum or pissasphaltum.

Another.

Now *Mathiolus* saith that all the Mummie which is brought into these parts is of this last kind & condition. For the Noblemen and chief of the province so religiously addicted to the monuments of their ancestors, would never suffer the bodies of their friends, and kindred to be transported hither for filthy gain, and such detested use, as we shall shew more at large at the end of this work. Which thing sometimes moved certain of our *French* Apothecaries, men wondrous audacious, and covetous, to steal by night the bodies of such as were hanged, and embalming them with Salt and Drugs they dried them in an Oven, so to sel them thus adulterated in stead of true Mummie. Wherefore we are thus compelled both foolishly and cruelly to devoure the mangled and putrid particles of the carkasses of the basest people of *Egypt*, or of such as are hanged, as though there were no other way to help or recover one bruised with a fall from a high place, than to bury man by an horrid insertion in their, that is, in mans guts. Now if this Drug were any way powerfull for that they require, they might perhaps have some pretence, for this their more than barbarous inhumanity. But the case stands thus, that this wicked kind of Drug, doth nothing help the diseased, in that case, wherefore and wherein it is administred, as I have tryed an hundred times, & as *Thevet* witnesses, he tryed in himself, when as he took some thereof by the advice of a certain *Jewish* Physitian in *Egypt*, from whence it is brought; but it also infers many troublesome symptomes, as the pain of the heart or stomach, vomiting and stink of the mouth.

What our Mummie usually is.

Mummie is no way good for contusions.

I perswaded by these reasons, do not only my self prescribe any hereof, to my Patients, but also in consultations, endeavour what I may, that it be not prescribed by others. It is far better according to *Galens* opinion in *Method. med.* to drink some oxycrate, which by its frigidty restrains the flowing blood, and by its tenuity of substance dissolves and discusses the congealed clots thereof. Many reasons of learned Physitians (from whom I have learned this History of Mummie) drawn from Philosophy, whereby they make it apparent, that there can be no use of this or that Mummie in contusions, or against flowing or congealed blood, I willingly omit, for that I think it not much beneficiall to Chirurgeons to insert them here. Wherefore I judg it better to begin to treat of combustions, or burns.

But hurtfull, and how? The effects of oxycrate in Contusions.

CHAP. VIII. Of Combustions and their differences.

ALL Combustions whether occasioned by Gunpowder, or by scalding oil, water, some metall or what things soever else, differ only in magnitude. These first cause pain in the part, and imprint in it an unnaturall heat. Which favouring of the fire, leaves that impression, which the Greeks call *Empyreuma*. There are more or lesse signs of this impression, according to the efficacy of the thing burning, the condition of the part burned, and stay upon the same. If the combustion be superficially, the skin rises into pustules and blisters, unlesse it be speedily prevented. If it be low or deep in, it is covered with an *Eschar* or crust, the burnt flesh by the force of the fire turning into that crusty hardnesse. The burning force of the fire, upon whatsoever part it falls, leaves a hot distemper therein, condensates, contracts, and thickens the skin, whence pain proceeds; from pain there comes an attraction of humors, from the adjacent and remote parts. These humors presently turned into waterish or serous moisture, whilst they seek to passe forth, and are hindred thereof by the skin condensated by the action of the fire, they lift it up higher, and raise the blisters which we see. Hence divers Indications are drawn, whence proceeds the variety of medicins for burns. For some take away the *Empyreuma*, that is, the heat of the fire, (as we term it) & asswage the pain; other hinder the rising of blisters; other some are fit to cure the ulcer, first to procure the falling away of the *Eschar*, then to cleanse, generate flesh and cicatrize it. Remedies fit to asswage pain, and take away the fiery heat, are of two kinds; for some do it by a cooling faculty, by which they extinguish the preternaturall heat, and repress or keep back the blood and humors, which flow into the parts by reason of heat and pain. Others endued with contrary faculties, are hot and attractive; as which by relaxing the skin, and opening the pores, resolve and dissipate the serous humors, which yeeld both beginning, and matter to the pustules, and so by accident asswage the pain and heat. Refrigerating things are cold water, the water of Plantain, Night-shade, Henbane, Hemlock; the juyces of cooling hearbs, as Purslane, Lettuce, Plantain, Houfleeck, Poppy, Mandrake and the like. Of these some may be compounded, as some of the fore-

The reason and symptomes of combustions

The cause of the blisters rising upon burns.

Variety of medicins to take away the heat and asswage the pain.

named

named juices beaten with the white of an egge; Clay beaten and dissolved in strong Vinegar; rock A-lome dissolved in water, with the whites of eggs beaten therein; writing ink mixed with Vinegar, and a little Camphire; *Vnguentum nutritum*, and also *Populeon* newly made. These and the like shall be now and then renewed chiefly at the first, untill the heat and pain be gone. But these same remedies must be applyed warm, for if they should be laid, or put to cold, they would cause pain, and consequently defluxion; besides also their strength could not passe, or enter into the part, or be brought into action; but so applyed they asswage pain, hinder inflammation and the rising of blisters.

CHAP. IX. Of hot and attractive medicins to be applyed to burnes.

Mongst the hot and attractive things which by rarifying, drawing out, and dissolving, asswage the pain and heat of combustions, the fire challenges the first place, especially when the burning is but small. For the very common people know and find by dayly experience, that the heat of the lightly burnt part vanishes away, and the pain is asswaged, if they hold the part which is burnt some preby while to the heat of a lighted candle, or burning coals; for the similitude causeth attraction. Thus the externall fire whilest it draws forth the fire which is internall and inuist into the part, is a remedy against the disease it caused and bred. It is also an easily made and approved remedy, if they presently after the burn apply to the grieved part raw Onions beaten with some salt. Now you must note, that this medicine takes no place, if it be once gone into an ulcer, for it would increase the pain and inflammation; but if it be applyed when the skin is yet whole and not excoriated, it doth no such thing, but hinders the rising of pustles and blisters. *Hippocrates* for this cause also uses this kind of remedy in procuring the fall of the *Eschar*. If any endeavour to gainsay the use of this remedy by that principle in Physick, which sayes, that contraries are cured by contraries, and therefore affirm that Onions according to the authority of *Galen*, being hot in the fourth degree, are not good for combustions; let him know that Onions are indeed potentially hot, and actually moist, therefore they rarifie by their hot quality, and soften the skin by their actuall moisture, whereby it comes to pass that they attract, draw forth, and dissipate the imprinted heat, and so hinder the breaking forth of pustles. To conclude, the fire, as we formerly noted, is a remedy against the fire. But neither are diseases alwayes healed by their contraries (saith *Galen*) but sometimes by their like; although all healing proceed from the contrary, this word *contrary*, being more largely and strictly taken, for so also a Phlegmon is often cured by resolving medicins, which healeth it by dissipating the matter thereof. Therefore Onions are very profitable for the burnt parts, which are not yet exulcerated or excoriated. But there are also many other medicins good to hinder the rising of blisters; such as new horse-dung fryed in oil of Wal-nuts or Roses, and applyed to the parts. In like manner the leaves of Elder or Dane-wort boyled in oil of nuts, and beaten with a little salt. Also quenched lime powdered and mixed with *Vnguentum Rosatum*. Or else the leaves of Cuckow-pint and Sage beaten together with a little salt. Also Carpenters Glue dissolved in water and anointed upon the part with a feather, is good for the same purpose. Also thick Vernish which polishers or sword cutlers use. But if the pain be more vehement, these medicins must be renewed 3 or 4 times in a day and a night, so to mitigate the bitterness of this pain. But if so be we cannot by these remedies hinder the rising of blisters, then we must presently cut them as soon as they rise, for that the humor contained in them, not having passage forth, acquires such acrimony that it eats the flesh which lyeth under it, and so causeth hollow ulcers: So by the multitude of causes and increase of matter the inflammation groweth greater, not only for nine dayes (as the common people prattle) but for far longer time; also some whiles for less time, if the body be neither repleat with ill humors, nor plethorick, and you have speedily resisted the pain and heat by fit remedies. When the combustion shall be so great as to cause an *Eschar*, the falling away must be procured by the use of emollient and humective medicins, as of greases, oils, butter, with a little *basilicon*, or the following ointment. *Rx Mucagin. psillii. & cydon. an. ʒiiij. gummi trag. ʒij. extrahantur cum aqua parietariae, olei liliorum ʒijss. cere novae q. s. fiat unguentum molle.* For ulcers and excoriations you shall apply fit remedies, which are those that are without acrimony, such as *unguentum album camphoratum, desiccativum rubrum, unguentum rosatum*, made without Venegar, or *nutritum* composed after this manner. *Rx lithargyri auri ʒiiij. ol. rosat. ʒiiij. ol. de papaver. ʒijss. ung. populeon. ʒiiij. camphorae ʒj. fiat unguentum in mortario plumbeo secundum artem.* Or oil of Eggs tempered in a Leaden mortar. Also unquenched lime many times washed and mixed with *unguentum rosatum*, or fresh butter without salt, and some yolks of eggs hard roasted. Or *Rx Butyri recent. sine sale, ustulati, & colati ʒvj. vitell. ovor. iiij. cerus. lot. a in aqua plantag. vel rosar. ʒss. tuthie similiter lot. a, ʒiiij. plumbi usti, & loti, ʒij. Misceantur omnia simul, fiat linimentum ut decet.* Or elie, *Rx cort. jambuc. viridis, & olei rosat. an. lib. j. bulliant simul lento igne, postea colentur, & adde olei ovorum ʒiiij. pul. ceruss. & tuthie prepar. an. ʒj. cere albe quantum sufficit, fiat unguent. molle secundum artem.* But the quantity of drying medicins may alwayes be encreased or diminished according as the condition of the ulcer shall seem to require. The following remedies, are fit to asswage pain, as the mucilages of Line seeds, of the seeds of *Psillium*, or Flea-wort, and quinces extracted in rosewater, or fair water, with the addition of a little camphire; and lest that it dry too speedily, adde thereto some oil of Roses. Also five or six yolks of eggs mixed with the mucilages of Line seed, the seed of *Psillium*, and quinces often renewed, are very powerfull to asswage pain. The women which attend upon the people in the Hospitall in *Paris*, do happily use this medicin against burns. *Rx Lard. confisi libram unam;* let it be dissolved in Rosewater, then strained through a linnen cloath, then wash it foure times with the water of hen-bane or some other of that kind, then let it be incorporated with eight yolks of new laid eggs, and so make an ointment. If the smart be great, as usually it is in these kinds of wounds, the ulcer or sores shall be covered over with a piece of Tiffany, lest you hurt them, by wiping them with somewhat a course cloth, and so also the matter may easily come forth, and

Medicins for an Eschar.

A description of Nutritum.

A remedy for burnes commonly used in the Hospitall of Paris.

and the medicins easily enter in. Also you must have a care when the eyelids, lips, sides of the fingers, neck, the armpits, hams, and bending of the elbow are burnt, that you suffer not the parts to touch one the other, without the interposition of some thing; otherwise in continuance of time they would grow and stick together. Therefore you shall provide for this, by fit placing the parts, and putting soft linnen rags between them. But you must note, that deep combustions, and such as cause a thicker *Eschar*, are less painfull, than such as are but only superficially. The truth hereof you may perceive by the example of such as have their limbs cut off, and seared or cauterised with an hot Iron; for presently after the cauterising is performed they feel little pain. For this great combustion takes away the sense, the vehemency of the sensory or thing affecting the sense, depriving the sensitive parts of their sense; As we have formerly noted when we treated of wounds and pains of the Nerves. The falling away of such *Eschars* shall be procured by somewhat a deep scarification which may pierce even to the quick, that so the humors which lye under it may enjoy freer perspiration, and emollient medicins may the freelier enter in, so to soak, moisten and soften the *Eschar* that it may at length fall away. The rest of the cure shall be performed by detergent and sarcotick medicins, adding to the former ointments metalline powders, when the present necessity shall seem so to require. But we cannot justly say in what proportion and quantity each of these may be mixed, by reason of that variety which is in the temper and consistence of bodies, and the stubbornness and gentleness of diseases. After a burn the scar which remaineth is commonly rough, unequal, and ill favoured: therefore we will tell you in our treatise of the plague how it must be smoothed, and made even.

Why deep combustions are less painfull then superficially.

I must not here omit to tell you, that Gunpowder set on fire doth often so penetrate into the flesh, not ulcerating nor taking off the skin, and so insinuate and thoroughly fasten it selfe into the flesh by its tenuity, that it cannot be taken or drawn out thence by any remedies, no not by *Phænigmes* nor vesicatories, nor scarification, nor ventoses, nor horns, so that the prints thereof alwayes remain, no otherwise than the marks which the Barbarians burn in their slaves, which cannot afterwards be taken away or destroyed by any Art.

Marks or spots made in the face by corns of Gunpowder cannot be taken away.

CHAP. X. Of a Gangrene and Mortification.

Certainly the malign symptomes which happen upon wounds, and the solutions of Continuity are many, caused either by the ignorance or negligence of the Chirurgion; or by the Patient, or such as are about him; or by the malignity and violence of the disease: but there can happen no greater then a Gangrene, as that which may cause the mortification and death of the part, and oft times of the whole body; wherefore I have thought good in this place to treat of a Gangrene, first giving you the definition, then shewing you the causes, signs, prognosticks, and lastly the manner of cure. Now a Gangrene is a certain disposition, and way to the mortification of the part, which it seizeth upon, dying by little and little. For when there is a perfect mortification, it is called by the Greeks *Sphacelos*, by the Latines *Syderatio*; our countrymen terme it the fire of Saint *Anthony* or Saint *Marcellus*.

Galen's ad Glaucanem.

CHAP. XI. Of the generall and particular causes of a Gangrene.

The most generall cause of a Gangrene is, when by the dissolution of the harmony and joint temper of the foure first qualities; the part is made unapt to receive the faculties, the Naturall, Vitall, and Animall spirits; by which it is nourished, lives, feels, and moves. For a part deprived by any chance of these as of the light, languishes and presently dyes. Now the particular causes are many; and these either primitive, or antecedent. The primitive or externall are combustions caused by things either actually or potentially burning; actually, as by fire, scalding oil or water, gunpowder fired and the like. But potentially by acrid medicins; as Sublimate, vitrioll, potentiall cauteries and other things of the same nature: for all these cause a great inflammation in the part. But the ambient air may cause great refrigerations, and also a Gangrene, which caused *Hippocrates lib. de Acr.* to call great refrigerations of the brain *Sphacelisme*. Therefore the unadvised and unfit application of cold and narcotick things, a fracture, luxation and great contusion, too strait bandages, the biting of beasts, especially of such as are venomous, a puncture of the Nerves and Tendons, the wounds of the nervous parts and joints, especially in bodies which are plethorick and repleat with ill humors, great wounds whereby the vessels which carry life are much cut, whence an *aneurisma*, and lastly many other causes, which perturb that harmony of the foure prime qualities which we formerly mentioned, and so infer a Gangrene.

The generall cause of a Gangrene.

The particular cause.

Cold causeth a Gangrene.

CHAP. XII. Of the Antecedent causes of a Gangrene.

Now the antecedent or internall and corporeall causes of a Gangrene, are plentiful and abundant defluxions of humors, hot or cold, falling into any part. For seeing the faculty of the part is unapt and unable to sustain and govern such plenty of humors, it comes to passe that the native heat of the part is suffocated and extinct for want of transpiration. For the Arteries are hereby so shut or pent up in a strait, that they cannot perform their motions of contraction and dilatation, by which their native heat is preserved and tempered. But then the Gangrene is chiefly incurable when the influx of humors first takes hold of the bones, and inflammation hath its beginning from them. For in the opinion of *Galen*, all these kind of affects which may befall the flesh, are also incident to the bones. Neither only a Phlegmon or inflammation; but also a rottenness and corruption.

How defluxions cause a Gangrene.

An incurable Gangrene.

Lib. de mor. pr. at. 1. 1. 1. 1.

ruption

ruption doth oft-times first invade and begin at the bones; for thus you may see many who are troubled with the Leprosie and French disease, to have their skin and flesh whole and fair to look on, whose bones notwithstanding are corrupt and rotten, and oft-times are much decayed in their proper substance. This mischief is caused by a venomous matter, whose occult qualitie we can scarce expresse by any other name than poyson inwardly generated. Oft-times also there is a certain acrid and stinking filth generated in flesh with a malign and old ulcer, with which if the bones chance to be moistened they become foul and at length mortified: of which this saying of *Hippocrates* is extant, Ulcers of a years continuance or longer, must necessarily foul the bone, and make the scars hollow. Whither also belongs this saying of the same party; An *Erisipelas* is ill in the laying bare of a bone. But this flowing venenate and gangrenous matter is somewhiles hot, as in pestilent Carbuncles, which in the space of four and twenty hours by causing an *eschar*, bring the part to mortification: otherwhiles cold, as we see it divers times happens in parts which are possess'd with a Gangrene, no pain, tumor, blackness, nor any other precedent sign of a Gangrene going before. For *John de Vigo* saith, that happened to a certain gentlewoman of *Genoa* under his cure.

Aph. 5. sect. 6.

A Gangrene by efflux of a cold matter.

A notable History.

Simple cold may cause a Gangrene.

A History.

What parts are usually taken by a Gangrene occasioned by cold.

I remember the same happened to a certain man in *Paris*, who supping merrily and without any sense of pain, went to bed, and suddainly in the night time a Gangrene seized on both his legs, caused a mortification without tumor, without inflammation; only his legs were in some places spread over with livid, black and green spots, the rest of the substance retaining his native colour: yet the sense of these parts was quite dead, they felt cold to the touch; and if you thrust your lancet into the skin no blood came forth. A Councell of Physicians being called, they thought good to cut the skin, and flesh lying under it, with many deep scarifications; which when I had done, there came forth a little black, thick and as it were congealed blood; wherefore this remedy, as also divers other, proved to no purpose, for in conclusion a blackish colour coming into his face, and the rest of his body, he dyed frantick. I leave it to the Readers judgement, whether so speedy, and suddainly cruell a mischief could proceed from any other than a venenate matter; yet the hurt of this venenate matter is not peculiar, or by its self. For oft-times the force of cold, whether of the encompassing air, or the too immoderate use of Narcotick medicins, is so great, that in a few hours it takes away life from some of the members, and divers times from the whole body, as we may learn by their example, who travell in great snowes, and over mountains congealed, and horrd with frost and ice. Hence also is the extinction of the native heat and the spirits residing in the part, and the shutting forth of that which is sent by nature to aid or defend it. For when as the part is bound with rigid cold, and as it were frozen, they cannot get nor enter therein. Neither if they should enter into the part, can they stay long there, because they can there finde no fit habitation, the whole frame and government of nature being spoiled, and the harmony of the four prime qualities destroyed, by the offensive dominion of predominant cold their enemy, whereby it cometh to passe that flying back from whence they first came; they leave the part destitute and deprived of the benefit of nourishment, life, sense and motion.

A certain Briton an Hostler in *Paris*, having drunk soundly after supper, cast himself upon a bed; the cold air coming in as a window left open, so took hold upon one of his legs, that when he waked forth of his sleep, he could neither stand nor goe. Wherefore thinking only that his leg was numb, they made him stand to the fire; but putting it very nigh, he burnt the sole of his foot without any sense of pain, some fingers thickness, for a mortification had already possessed more than halfe his leg. Wherefore after he was carryed to the Hospitall, the Chirurgion who belonged thereto, endeavoured by cutting away of the mortified leg to deliver the rest of the body from imminent death; but it proved in vain; for the mortification taking hold upon the upper parts, he dyed within three dayes, with troublesome belching and hicketing, raving, cold sweat, and often swoounding. Verily all that same winter, the cold was so vehement that many in the Hospitall of *Paris* lost the wings or sides of their nostrills, seized upon by a mortification without any putrefaction. But you must note, that the Gangrene which is caused by cold, doth first and principally seize upon the parts most distant from the heart, the fountain of heat; to wit, the feet and legs; as also such as are cold by nature, as gristly parts, such as the nose and eares.

CHAP. XIII. Of the signs of a Gangrene.

The signs of a Gangrene which inflammation or a phlegmon hath caused, are pain and pulsation without manifest cause, the sudden changing of the fiery and red colour into a livid or black, as *Hippocrates* shewes where he speaks of the Gangrene of a broken heel. I would have you here to understand the pulsifick pain not only to be that which is caused by the quicker motion of the Arteries, but that heavy and pricking which the contention of the naturall heat doth produce by raising a thick cloud of vapours from these humors which the Gangrene sets upon. The signs of a Gangrene caused by cold, are, if suddainly a sharp pricking and burning pain assaileth the part; for *penetrabile frigus adurit*, (i) piercing cold doth burn: if a shining redness as if you had handled snow, presently turn into a livid colour; if in stead of the accidentall heat which was in the part, presently cold and numbness shall possess it, as if it were shook with a quartain fever. Such cold if it shall proceed so far as to extinguish the native heat, bringeth a mortification upon the Gangrene; also oft-times convulsions & violent shaking of the whole body, wondrous troublesome to the brain & the fountains of life. But you shall know Gangrenes caused by too strait bandages, by fracture, luxation, and contusion, by the hardness which the attraction and flowing down of the humors hath caused, little pimples or blisters spreading or rising upon the skin by reason of the great heat, as in a combustion; by the weight of the part occasioned through the defect of the spirits not now sustaining the burden

See a lib. de fractur.

What a pulsifick pain is.

Signs of a Gangrene proceeding of cold.

Signs of Gangrenes proceeding from strait bandages, or ligatures, &c.

den of the member; and lastly from this, the pressing of your finger upon the part, it will leave the print thereof as in an *oedema*; and also from this, that the skin cometh from the flesh without any manifest cause.

Now you shall know Gangrenes arising from a bite, puncture, *aneurisma*, or wound in plethorick and ill bodies, and in a part indued with most exquisite sense, almost by the same signs as that which was caused by inflammation. For by these and the like causes, there is a far greater defluxion and attraction of the humors than is fit, when the perspiration being intercepted and the passages stoppt, the native heat is oppressed and suffocated. But this I would admonish the young Chirurgeon, that when by the fore-mentioned signs he shall find the Gangrene present, that he do not defer the amputation for that he finds some sense, or small motion yet residing in the part. For oft-times the affected parts are in this case moved not by the motion of the whole muscle, but only by means, that the head of the muscle is not yet taken with the Gangrene: with moving it self by its one strength, also moves its proper and continued tendon and tail though dead already; wherefore it is ill to make any delay in such causes.

Signs of a Gangrene occasioned by a bite, puncture, &c.

CHAP. XIII. Of the Prognosticks in Gangrenes.

Having given you the signs and causes to know a Gangrene; it is fit we we also give you the prognostick. The fierceness and malignity thereof is so great, that unlesse it be most speedily withstood the part it self will dye, and also take hold of the neighbouring parts by the contagion of its mortification: which hath been the cause that a Gangrene by many hath been termed an *Esthiomenos*. For such corruption creeps out like poyson, and like fire eats, gnaws, and destroyes all the neighbouring parts, untill it hath spread over the whole body. For as Hippocrates writes, *Lib. de vulner. capit. 15*; *Mortui & viventis nulla est proportio*, (i) there is no proportion between the dead and living. Wherefore it is fit presently to separate the dead from the living; for unlesse that be done, the living wil dye, by the contagion of the dead. In such as are at the point of death a cold sweat flows over all their bodies: they are troubled with ravings, and watchings, belchings and hicketing molest them; and often swoundings invade them, by reason of the vapours abundantly and continually raised from the corruption of the humors and flesh, and so carried to the bowells and principall parts, by the Veins, Nerves, and Arteries. Wherefore when you have foretold these things to the friends of the Patient, then make haste to fall to your work.

Why a Gangrene is called *Esthiomenos*.

The quick impatient of the dead.

CHAP. XV. Of the generall cure of a Gangrene.

The Indications of curing Gangrenes are to be drawn from their differences, for the cure must be diversly instituted according to the essence and magnitude. For some Gangrenes possess the whole member; others only some portion thereof; some are deep; others some superficial only. Also you must have regard to the temper of the body. For soft and delicate bodies, as of children, women, Eunuches, and idle persons, require much milder medicins, than those who by nature and custome, or vocation of life, are more strong and hardy, such as husbandmen, labourers, mariners, huntsmen, porters, and men of the like nature who live sparingly and hardly. Neither must you have respect to the body in generall, but also to the parts affected; for the fleshy and musculous parts, are different from the solid, as the nerves and joints, or more solid, as the *Vertebrae*. Now the hot and moist parts, as the privities, mouth, womb, and fundament, are easly and sooner taken hold of by putrefaction, wherefore we must use more speedy means to help them. Wherefore if the Gangrene be chiefly occasioned from an internall cause, he must have a dyet prescribed for the decent and fitting use of the six things not naturall. If the body be plethorick, or full of ill humors; you must purge, or let blood by the advice of a Physitian. Against the ascending up of vapours to the noble parts, the heart must chiefly be strengthened with Treacle dissolved in Sorrell, or *Carduus* water; with a bole of Mithridate, the conserves of Roses and Buglosse; and with Opiates made for the present purpose according to Art; this following Apozeme shall be outwardly applyed to the region of the heart. *R. aquae rosar. & nenuphar. an. ʒ iiij. aceti scillitici ʒ j. corallorum, santalorum alborum & rubrorum, rosar. rub. in pulver. redactarum, & spodii, an. ʒ j. mithrid. & theriacae, an. ʒ ij ʒ. trochiscorum de Caphura ʒ ij. flor. cardial. in pollin. redactarum, p. ij. croci ʒ j. ex omnibus in pollinem redactis, fiat epithema.* Which may be applyed upon the region of the heart with a scarlet cloth or sponge. These are usually such as happen in the cure of every Gangrene.

Various Indications of curing a Gangrene.

What parts soonest taken hold by a Gangrene.

A cordiall Epithema.

CHAP. XVI. Of the particular cure of a Gangrene.

The cure of a Gangrene, caused by the too plentiful and violent defluxion of humors suffocating the native heat, by reason of great Phlegmons, is performed by evacuating and drying up the humors, which putrefie by delay and collection in the part. For this purpose scarifications and incisions, great, indifferent, small, deep and superficially according to the condition of the Gangrene, are much commended; that so the burdened part may enjoy the benefit of perspiration; and the contained humors, of distillation, or evacuation of their sooty excrements. Let incisions be made when the affect is great, deep in, and neer to mortification. But scarifications may be used when the part first begins to putrefie, for the greatnesse of the remedy must answer in proportion to that of the disease. Wherefore if it penetrate to the bones, it will be fit, to cut the skin and flesh with many and deep incisions, with an incision knife made for that purpose; yet take heed of cutting the larger nerves and vessels, unlesse they be wholly putrefied, for if they be not yet putrefied, you shall make your incisions in the spaces between them; if the Gangrene be lesse, we must rest

The cure of a Gangrene made by inflammation.

satisfied with only scarifying it. When the scarifications and incisions are made, we must suffer much blood to flow forth, that so the conjunct matter may be evacuated. Then must we apply and put upon it such medicins as may by heating, drying, resolving, cleansing and opening, amend and correct the putrefaction, and by piercing to the bottom may have power to overcome the virulencie already impact in the part. For this purpose Lotions made of the lye of the Ashes of fig-tree or Oak wherein Lupins have been throughly boyled are good. Or you may with lesse trouble make a medicin with salt water, wherein you may dissolve Aloes and *Aegyptiacum*, adding in the conclusion a little *Aqua vitæ*; for *aqua vitæ* and calcined vitrioll are singular medicins for a Gangrene. Or *Rx. acet. opimi ℥j. mel. ros. ℥iiij. syrup. acetosi ℥iiij. salis com. ℥v. bulliant simul, adde aqua vitæ, ℥℥. f.* Let the part be frequently washed with this medicin, for it hath much force to repress Gangrenes. After your Lotion, lay *Aegyptiacum* for a Liniment, and put it into the incisions; for there is no medicin, more powerfull against putrefaction, for by causing an *Eschar*, it separates the putrid flesh from the sound. But we must not in this kind of affect expect that the putrid flesh may of it self fall from the sound; but rather cut off with your incision knife or sissors, whatsoever thereof you can, and then put to it *Aegyptiacum* as oft as need shall require. The knowledg hereof may be acquired from the colour, smell, and sensibleness of the flesh it self. The description of the *Aegyptiacum*, whose wondrous effects I have often tryed in these causes, is this. *Rx. flor. & ris, aluminis roch. mellis com. an. ℥iiij. aceti acerrimi ℥v. salis com. ℥j. vitrioli rom. ℥℥. sublimati pul. ℥ij. bulliant omnia simul ad ignem, fiat unguent.* If the force of the putrefaction in the part be not so great, a weaker *Aegyptiacum* may serve. When you have put in the *Aegyptiacum*, then presently lay the following Cataplasme thereupon. For it hinders putrefaction, resolves, cleanses and dryes up the virulent sanies, and by the dry subtilery of the parts penetrates into the member, strengthens it, and asswages the pain. *Rx. farin. fabar. bordei orobi, lent. lupin. an. ℥℥. sal. com. mellis roj. at. an. ℥iiij. succi absinth. marrub. an. ℥iiij. aloes, mastiches, myrrha, & aqua vit. an. ℥ij. oxymelitis simpl. quantum sufficit; fiat Cataplasma molle secundum artem;* Somewhat higher than the part affected, apply this following astringent, or defensitive, to hinder the flowing down of the humors into the part, and the rising up of the vapours from the putrid part into the whole body. *Rx. olei rosati, & myrtill. an. ℥iiij. succi plantag. solani, sempervivi, an. ℥ij. album ovorum 5. boli armeni, terræ sigillatæ subtiliter pulverisatorum, an. ℥j. oxycrati quantum sufficit, misce ad usum dictum.* But these medicins must be often renewed. If the grief be so stubborn, that it will not yeeld to the described remedies, we must come to stronger, to wit, Cauteries, after whose application, *Galen* bids to put upon it the juice of a Leek with salt beaten and dissolved therewith, for that this medicin hath a piercing and drying faculty, and consequently to hinder putrefaction. But if you prevail nothing with Cauteries, then must you come to the last remedy and refuge, that is, the amputation of the part; For according to *Hippocrates*, to extrem diseases exquisitely extrem remedies are best to be applied. Yet first be certain of the mortification of the part; for it is no little or small matter to cut off a member without a cause.

Therefore I have thought it fit to set down the signs, whereby you make know a perfect and absolute mortification.

CHAP. XVII. The signs of a perfect Necrosis or Mortification.

You shall certainly know that a Gangrene is turned into a Sphacell, or mortification and that the part is wholly and throughly dead, if it look of a black colour, and be colder than stone to your touch, the cause of which coldness is not occasioned by the frigidity of the air; if there be a great softness of the part, so that if you presse it with your finger it rises not again, but retains the print of the Impression. If the skin come from the flesh lying under it; if so great and strong a smell exhale (especially in an ulcerated Sphacell) that the standers by cannot endure or suffer it; if a sanious moisture, viscid, green or blackish flow from thence; if it be quite destitute of sense and motion, whether it be pulled, beaten, crushed, pricked, burnt, or cut off. Here I must admonish the young Chirurgeon, that he be not deceived concerning the losse or privation of the sense of the part. For I know very many deceived as thus; the Patients pricked on that part would say they felt much pain there. But that feeling is oft deceitfull, as that which proceeds rather from the strong apprehension of great pain which formerly raigned in the part, than from any faculty of feeling as yet remaining. A most clear and manifest argument of this false and deceitfull sense appears after the amputation of the member; for a long while after they will complain of the part which is cut away.

Verily it is a thing wondrous strange and prodigious, and which will scarce be credited, unless by such as have seen with their eyes, and heard with their ears the Patients who have many months after the cutting away of the Leg, grievously complained that they yet felt exceeding great pain of that leg so cut off. Wherefore have a speciall care lest this hinder your intended amputation; a thing pitifull, yet absolutely necessary for to preserve the life of the Patient and all the rest of his body, by cutting away of that member which hath all the signs of a Sphacell and perfect mortification; for otherwise the neglected fire will in a moment spread over all the body, and take away all hope of remedy; for thus *Hippocrates* wisheth: That Sections, Ustions, and Treparations must be performed as soon as need requires.

CHAP. XVIII. Where Amputation must be made.

It is not sufficient to know that Amputation is necessary, but also you must learn in what place of the dead part, it must be done, and herein the wisdom and judgment of the Chirurgeon is most apparent. Art bids to take hold of the quick, and to cut off the member in the sound flesh; but the same art wisheth us, to preserve whole that which is sound, as much as in us lies. I will shew thee by a familiar example how thou maist carry thy self in these difficulties. Let

The controversy decided.

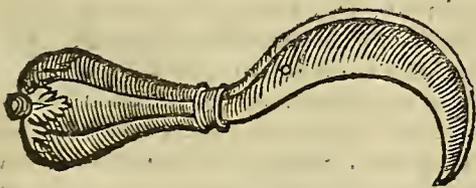

us suppose, that the foot is mortified even to the ankle; here you must attentively mark in what place you must cut it off. For unlesse you take hold of the quick flesh in the amputation, or if you leave any putrefaction, you profit nothing by amputation, for it will creep and spread over the rest of the body. It befits Physick ordained for the preservation of mankind, to defend from the iron or instrument & all manner of injury, that which enjoyes life and health. Wherefore you shall cut off as little of that which is found as you possibly can; yet so that you rather cut away that which is quick, than leave behind any thing that is perished, according to the advice of *Celsus*. Yet oft-times the commodity of the action Lib. 7. cap. 33. of the rest of the part, and as it were a certain ornament thereof, changes this counsell: For if you take these two things into your consideration they will induce you in this propounded case and example, to cut off the Leg some five fingers breadth under the knee. For so the Patient may more fitly use the rest of his Leg and with lesse trouble, that is, he may the better go on a wooden Leg; for otherwise, if according to the common rules of Art, you cut it off close to that which is perished, the Patient will be forced with trouble to use three Legs in stead of two.

For I so knew Captain *Francis Clerk*, when as his foot was stricken off with an iron bullet shot forth of a man of war, and afterwards recovered and healed up, he was much troubled and wearied with the heavy and unprofitable burden of the rest of his Leg, wherefore though whole and sound he caused the rest thereof to be cut off, some five fingers breadth below his knee; and verily he useth it with much more ease and facility than before in performance of any motion. We must do otherwise if any such thing happen in the Arm; that is, you must cut off as little of the sound part as you can. For the action of the Legs much differ from these of the Arms, and chiefly in this that the body rests not, neither is carried upon the Arms, as it is upon the feet and Legs. An observable History.

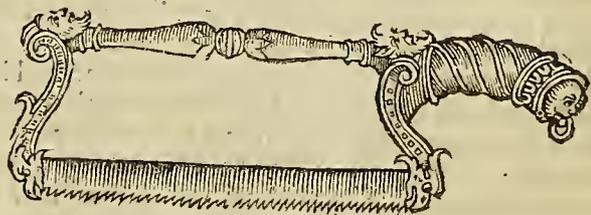

CHAP. XIX. How the section or amputation must be performed.

The first care must be of the Patients strength, wherefore let him be nourished with meats of good nutriment, easie digestion, and such as generate many spirits; as with the yolks of Eggs, and bread tosted and dipped in Sack or Muscadine. Then let him be placed, as is fit, and drawing the muscles upwards towards the sound parts, let them be tyed with a strait ligature a little above that place of the member which is to be cut off, with a strong and broad fillet like that which women usually bind up their hair withall. This ligature hath a threefold use; the first is, that it hold the muscles drawn up together with the skin, so that retiring back presently after the performance of the work, they may cover the ends of the cut bones, and serve them in stead of bouldsters The Ligature of the part. or pillows when they are healed up, & so suffer with lesse pain the compression in sustaining the rest of the body; besides also by this means the wounds are the sooner healed and cicatrized; for by how much more flesh or skin is left upon the ends of the bones, by so much they are the sooner healed and cicatrized. The second is, for that it prohibits the flux of blood by pressing and shutting up the veins and arteries. The third is, for that it dulls the sense of the part by stupefying it, the animall spirits by the strait compressing being hindred from passing in by the Nerves. Wherefore when you have made your ligature, cut the flesh even to the bone with a sharpe and well cutting incision knife, or with a crooked knife, such as is here expressed.

A crooked knife fit for dismembring; or a dismembring knife.

The Figure of such a Saw.

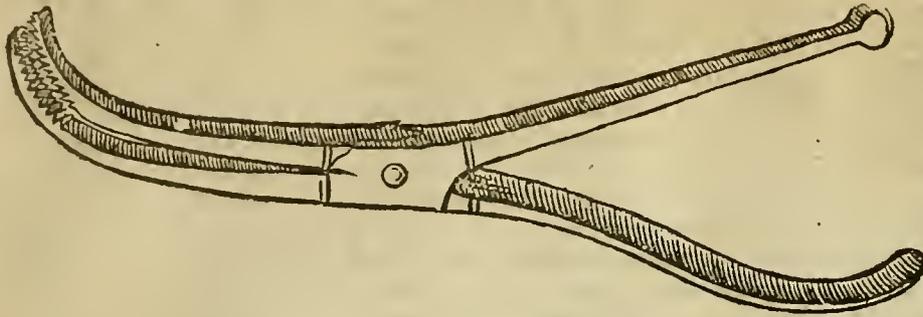

Now you must note, that there usually lies between the bones, a portion of certain muscles which you cannot easily cut with a large incision or dismembring knife; wherefore you must carefully divide it and separate it wholly from the bone, with an instrument made neatly like a crooked incision knife. I thought good to advertise thee hereof; for if thou shouldest leave any thing besides the bone to be divided by the Saw, you would put the Patient to excessive pain in the performance thereof; for oft things, as flesh, tendons and membranes, cannot be easily cut with a Saw. Therefore when you shall come to the bared bone, all the other parts being wholly cut asunder and divided, you shall nimbly divide it with a little Saw about some foot and three inches long, and that as near to the sound flesh as you can. And then you must smooth the front of the bone which the Saw hath made rough. A caution to be observed.

CHAP. XX. How to stanch the bleeding when the member is taken off.

When you have cut off and taken away the member, let it bleed a little according to the strength of the Patient, that so the rest of the part may afterwards be lesse obnoxious to inflammation and other symptomes; Then let the veins and arteries be bound up as speedily and straitly as you can; that so the course of the flowing blood may be stopped and wholly stayed. Which may be done by taking hold of the vessels with your Crows beak, whereof the figure follows.

The Crowes beak fit for to draw the vessells forth of the flesh wherein they lye hid, that so they may be tyed or bound fast.

How to draw forth the vessells and bind them.

The ends of the vessells lying hid in the flesh, must be taken hold of and drawn with this instrument forth of the muscles whereinto they presently after the amputation withdrew themselves, as all parts are still used to withdraw themselves to-

wards their originalls. In performance of this work, you need take no great care, if you together with the vessells comprehend some portion of the neighbouring parts, as of the flesh, for hereof will ensue no harme; but the vessells will so be consolidated with the more ease, than if they being bloodlesse parts should grow together by themselves. To conclude, when you have so drawn them forth, bind them with a strong double thred.

CHAP. XXI. How after the blood is stanch'd, you must dresse the wounded member.

How the lips of the dismembred part are to be joined together.

When you have tyed the Vessells, loose your Ligature which you made above the place of amputation; then draw together the lips of the wound with four stiches made acrossse, having taken good hold of the flesh; for thus you shall draw over the bones that part of the skin and cut muscles drawn upwards before the amputation, and cover them as close as you can, that so the air may the lesse come at them, and that so the wound may be the more speedily agglutinated. But when we say, draw together the lips of the wound with four stiches, you must not so understand it, as that you must endeavour, to draw them so close as to touch each other, for that is impossible; for the stiches would sooner break out, and so the part would lye bare. Wherefore it will be sufficient to draw them indifferent close together, that so you may suffer the skin and flesh thereunder to enjoy its former liberty which it posses before the drawing up, and so in fine by natures assistance, the wound may be the more casily agglutinated.

CHAP. XXII. How you must stop the bleeding, if any of the bound up vessells chance to get loose.

The business hitherto being performed as we said, if peradventure it happen that any bandage of any of the vessells be unloosed, then must you again bind the member with that kind of Ligature which you did before the amputation thereof. Or else, which is better, more easie and lesse painfull, let your servant take hold of the member with both his hands, pressing his fingers strait, stop the passage of the loosed vessell, for so he may stanch the bleeding. Then let the work-master take a needle some four fingers long, square, and having sharp edges, drawing after it a three or four doubled strong thred. With this let him bind the vessell after the following manner. Let him thrust his needle on the outside into the flesh, some half fingers breadth from the loosed vessell untill he come to the end thereof, then let him put it about it, and bring it back again, but so that there be no more than the space of a fingers breadth between the going in, and coming forth of the needle. In this space let him put a linnen rag three or four times doubled, and thereupon bind somewhat strait the two ends of the thred together. For so he shall hinder the knot from hurting the flesh which lies under it in the bindings, and also add strength thereto. For so the bound up orifice of the vessell will in short space be agglutinated to the adjoining flesh, and that so firmly, that there hath never been seen any one drop of blood to have flowed from a vessell so bound up. But if the blood which flows forth proceed from any small vessell, you must not use this future and ligature, nor make any such great matter thereof; for it will quickly be stanch'd by the only application of Astringents presently to be mentioned.

The Hemorrhagic of small vessells is norro heregarded.

CHAP. XXIII. How to perform the residue of the cure of the amputated member.

Now must we shew what medicins are fitting to be applyed after the amputation of a member; which are Emplasticks, as these which exceedingly conduce to green wounds. As *Rx boli arm. ℥iiij. farin. vol. ℥iiij. picis, resine, an. ℥ij. pulverisentur omnia subtiliss. & simul mixtis fiat pulvis*; herewith let the wound be strewed, and lay thereupon dry Lint; but let the following repercussive or defensitive be applyed to the member. *Rx Album ovorum vj. boli arm. sang. drac. gypsi, terra sigill. aloes, mastiches, gallar. combust. an. ℥ij. in pollinem redigantur omnia, & bene agitentur, addendo olei rosarum & myrtil. an. ℥j. fiat defensivum ad formam mellis*. This ointment must be applyed upon stoops dipped in Oxycrate, and that so that it may not only cover the cut member; but also be spread further and cover the neighbouring parts; as when the Leg is cut off, it must be laid upon the joint, and spread higher than the knee, some four fingers upon the thigh; for it hath not only a repercussive faculty, but it also strengthens the part, hinders defluxion by tempering the blood, asswaging pain, and hindring inflammation. It will also be good to moisten your double cloths and bandages in Oxycrate; then must you place the member in an indifferent posture upon a pillow stuffed with oaten huskes or chaffe, Stags hair, or wheat bran. It must not be stirred after the first dressing (unless great necessity urge) for four dayes in winter, but somewhat

like, even unto the perfect agglutination and cicatrization of the wound, and you may of your self devie other things, such as these; as occasion shall offer its self.

CHAP. XXIII. *What just occasion moved the Author to devise this new form of remedy, to stanch the blood after the amputation of a member, and to forsake the common way used almost by all Chirurgions; which is, by application of actuall cauteries.*

Verily I confess, I formerly have used to stanch the bleeding of members after amputation, after another manner than that I have a little before mentioned. Whereof I am ashamed, and a-
grieved; But what should I do? I have observed my masters whose method I intended to fol-
low, alwaies to do the like; who thought themselves singularly well appointed to stanch a
flux of blood, when they were furnished with various store of hot Irons and caustick medicins, which
they would use to the dismembred part, now one, then another, as they themselves thought meet. Which
thing cannot be spoken, or but thought upon without great horror, much lesse acted. For this kind of
remedy could not but bring great and tormenting pain to the Patient, seeing such fresh wounds made
in the quick and sound flesh are endued with exquisite sense. Neither can any caustick be applyed to
nervous bodies, but that this horrid impression of the fire will be presently communicated to the in-
ward parts, whence horrid symptomes ensue, & oft-times death it self. And verily of such as were burnt,
the third part scarce ever recovered, and that with much adoe, for that combust wounds difficultly come
to cicatrization; for by this burning are caused cruell pains, whence a Fever, Convulsion, and oft-
times other accidents worse than these. Adde hereunto, that when the eschar fell away, oft-times a new
hæmorrhage ensued, for stanching whereof they were forced to use other caustick and burning Instru-
ments. Neither did these good men know any other course; so by this repetition there was great losse
and wast made of the fleshy and nervous substance of the part. Through which occasion the bones were
laid bare, whence many were out of hope of cicatrization, being forced for the remainder of their
wretched life to carry about an ulcer upon that part which was dismembred; which also took away
the opportunity of fitting or putting to of an artificiall leg or arm in stead of that which was taken
off. Wherefore I must earnestly entreat all Chirurgions, that leaving this old, and too too cruell way
of healing, they would embrace this new, which I think was taught me by the speciall favour of the
sacred Deity, for I learnt it not of my masters, nor of any other, neither have I at any time found it used
by any. Only I have read in *Galen*, that there was no speedier remedy for stanching of blood, than to
bind the vessells through which it flowed towards their roots, to wit, the Liver and Heart. This pre-
cept of *Galen*, of binding and sowing the Veins and Arteries in the new wounds, when as I thought it
might be drawn to these which are made by the amputation of members, I attempted it in many; yet so
that at first in my budding practise thereof, I alwaies had my cauteries and hot Irons in a readinesse,
that

that if any thing happened otherwise then I expected in this my new work, I might fetch succour from the ancient practice, untill at length confirmed by the happy experience of almost an infinite number of particulars, I bid eternally adieu, to all hot Irons and cauteries which were commonly used in this work. And I think it fit that Chirurgeons do the like. For antiquity and custome in such things as are performed by Art, ought not to have any sway, authority or place contrary to reason, as they oft-times have in civill affaires; wherefore let no man say unto us, that the Ancients have alwayes done thus.

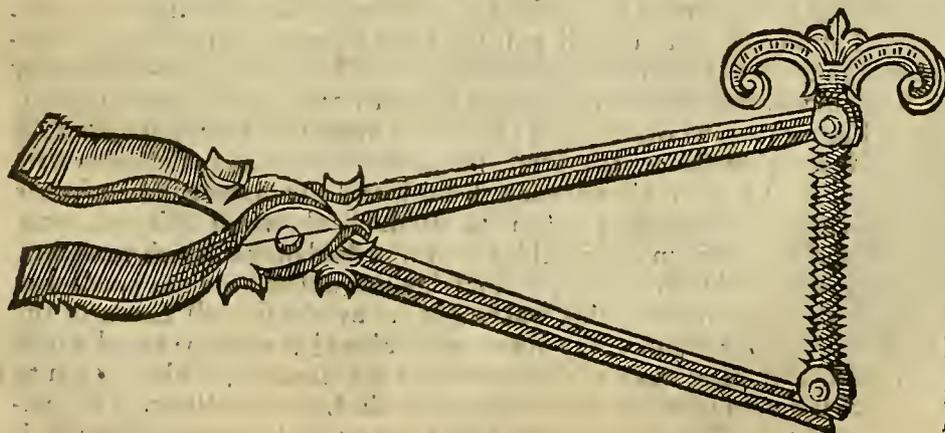

CHAP. XXV. *The practise of the former precepts is declared, together with a memorable history of a certain souldier, whose arm was taken off at the Elbow.*

A History.

Think it fit to confirm by an example the prescribed method of curing a Gangrene and Mortification. Whilst I was Chirurgeon to the Marshall of Montejan at Turin, a certain common souldier received a wound on his wrist with a musket bullet, by which the bones and tendons being much broken, and the nervous bodies cruelly torn, there followed a Gangrene and at length a mortification even to the Elbow; besides also an inflammation seized upon the middle part of his Chest, and there was as it were a certain disposition to a Gangrene, whereby it followed that he was painfully and dangerously troubled with belchings, hickettings, watchings, unquietnesse and frequent swoondings, which occasioned many Chirurgeons to leave him as desperate. But it so fell out, that I overcome by his friends intreaty, undertook the cure of this wretched person, destitute of all humane help. Wherefore knowing the mortification by its signs, I cut off the arm by the elbow as speedily as I could, making first the ligature, whereof I made mention; I say I took it off not with a saw, but only with an incision knife, cutting in sunder the ligaments which held the bones together, because the sphacell was not passed the joint of the Elbow. Neither ought this section to be counted strange, which is made in a joint; for Hippocrates much commends it, and saith that it is easily healed, & that there is nothing to be feared therein besides swoounding, by reason of the pain caused by cutting the common tendons & ligaments. But such incision being made, the former ligature could not hinder, but much blood must flow from thence, by reason of the large vessels that run that way. Wherefore I let the blood to flow plentifully so to disburden the part, and so afterwards to free it from the danger and fear of inflammation and a Gangrene; then presently I stanchd the blood with an hot Iron, for as yet I knew no other course. Then gently loosing the ligature I scarifie that part of the brawn of the Arm which was gangrenated, with many and deep incisions, shunning and not touching the inner part, by reason of the multitude of the large vessels and Nerves which run that way; then I presently applyed a cautery to some of the incisions, both to stanch the bleeding, and draw forth the virulent sanies which remained in the part. And then I assailed and overcame the spreading putrefaction by putting and applying the formerly prescribed medicins; I used all sorts of restrictive medicins, to stay the inflammation of the Chest; I also applyed Epithema's to the region of the heart, and gave him cordial potions and boles, neither did I desist from using them untill such time as his belching, hicketting and swoondings had left him. Whilst I more attentively intended these things, another mischief assails my Patient, to wit, Convulsions, and that not through any fault of him or me, but by the naughtinesse of the place wherein he lay, which was in a Barn every where full of chinks and open on every side, and then also it was in the midst of winter raging with frost and snow and all sorts of cold; neither had he any fire or other thing necessary for preservation of life, to lessen these injuries of the air and place; Now his joints were contracted, his teeth set, and his mouth and face were drawn awry, when as I pitying his case made him to be carried into the neighbouring Stable which smoaked with much horse dung, and bringing in fire in two chafendishes, I presently anointed his neck and all the spine of his back, shunning the parts of the Chest, with liniments formerly described for convulsions; then straight way I wrapped him in a warm linnen cloth, and buried him even to the neck in hot dung, putting a little fresh straw about him; when he had stayed there some three dayes, having at length a gentle scouring or flux of his belly, and plentiful sweat, he begun by little and little to open his mouth and teeth which before were set and close shut. Having got by this means some opportunity better to do my businessse, I opened his mouth as much as I pleased, by putting this following Instrument between his teeth.

A Dilater made for to open the mouth and teeth by the means of a screw in the end thereof.

Now drawing out the Instrument I kept his mouth open by putting in a willow stick on each side thereof, that so I might the more easily feed him with meats soon made, as with Cows milk and rear eggs, untill he had recovered power to eat, the convulsion having left him. He by this means freed from the Convulsion, I then again

begun the cure of his arm, and with an actuall cautery sear the end of the bone, so to dry up the perpetuall

petuall afflux of corrupt matter. It is not altogether unworthy of your knowledge, that he said, how that he was wondrously delighted by the application of such actuall cauteries, a certain tickling running the whole length of the arm by reason of the gentle diffusion of the heat by the applying the caustick; which same thing I have observed in many others; especially in such as lay upon the like occasion in the Hospitall of Paris. After this cauterizing there fell away many and large scales of the bone, the freer appulse of the air than was fit making much thereto; besides when there was place for fomentation, with the decoction of red Rose leaves, Wormwood, Sage, Bay leaves, flowers of Camomil, Melilote, Dill, I so comforted the part that I also at the same time by the same means drew and took away the virulent Sanies, which firmly adhered to the flesh and bones. Lastly, it came to passe, that by Gods assistance, these means I used, and my carefull diligence, he at length recovered. Wherefore I would admonish the young Chirurgion, that he never account any so desperate, as to give him for lost, content to have let him go with prognosticks; for as an ancient Doctor writes; that as in Nature, so in diseases there are also Monsters.

A fomentation for a Convulsion.

Monsters or miracles in diseases.

The End of the Twelfth Book.

THE THIRTEENTH BOOK.

CHAP. I. Of the nature, causes and differences of Ulcers.

Having already handled and treated of the nature, differences, causes, signs and cure of fresh and bloody wounds, reason and order seem to require that we now speak of Ulcers; taking our beginning from the ambiguity of the name. For according to Hippocrates, the name of Ulcer most generally taken may signifie all or any solution of Continuity; In which sense it is read that all pain is an Ulcer. Generally, for a wound and Ulcer properly so called; as appears by his Book, de Vlcerebus. Properly, as when he saith, it is a sign of death when an Ulcer is dried up through an Atrophia, or defect of nourishment. We have here determined to speak of an Ulcer in this last and proper signification. And according thereto we define an Ulcer to be the solution of Continuity in a soft part, and that not bloody, but sordid and unpure, flowing with quitture, Sanies or any such like corruption, associated with one or more affects against nature, which hinder the healing and agglutination thereof; or that we may give you it in fewer words according to Galens opinion; An ulcer is a solution of Continuity, caused by Erosion. The causes of Ulcers are either internall or externall. The internall are through the default of humors peccant in quality rather than in quantity, or else in both, and so making erosion in the skin and softer parts by their acrimony and malignity; now these things happen either by naughty and irregular diet, or by the ill disposition of the entrails, sending forth and emptying into the habit of the body this their ill disposure. The externall causes are, the excessse of cold seising upon any part, especially more remote from the fountain of heat, whence follows pain, whereunto succeeds an attraction of humors and spirits into the part, and the corruption of these so drawn thither by reason of the debility or extinction of the native heat in that part, whence lastly ulceration proceeds. In this number of externall causes may be ranged, a stroak, contusion, the application of sharp and acrid medicins, as causticks, burns; as also impure contagion, as appears by the virulent ulcers acquired by the filthy copulation or too familiar conversation of such as have the French disease. How many and what the differences of Ulcers are, you may see here described in this following Scheme.

The divers acceptions of an Ulcer. Sent. 34. sect. 2. lib. de fract.

The externall causes.

A Table of the differences of Ulcers.

An Ulcer is an impure solution of continuity in a soft part, flowing with filth and matter or other corruption, whereof there are two chief differences; for one

Is simple and solitary without complication of any other affect against nature, and this varies in differences; either

Or common and accidentall, and these drawn, either
 From their time; whence an Ulcer is tearmed new; old, of short or long cure and duration.
 From their appearance; whence one is called an apparent Ulcer, another a hidden and occult Ulcer.
 From their manner of generation; as if it be made by a heavy, bruising, cutting, pricking or corroding things; whence a cut, torn, and mixt Ulcer.
 From their site; whence an Ulcer before, behind, above, below, in the head, tail, or belly of a Muscle.
 From that part it seises upon; whence an Ulcer in the flesh and skin, or feeding upon the gristles or bones, such as these of the nose, the palat of the mouth, and ears.
 From other common accidents; whence a Telephian Ulcer; that is, such an Ulcer as Telephus had. A Chironian, which needs the hand and art of Chiron. A Cancryous, which resembles a Cancer.

With the cause, whence an Ulcer } Is Cachoymick, Catarrhoick or venenate, that is, which a Cachoymia or Repletion of ill humors, a Catarrh, or poison cherishes or feeds.

Is compound and many and various wayes complicated, as

Distemper whether simple or compound, whence an Ulcer is } Hot. Cold. Dry. Moist. Mixt.

With the disease, as from } Swelling or Tumor, whence a } Pblegmonous Erysipelous Oedematous Scirrbus Cancrous } Ulcer.

Solution of continuity, or any other discommodity, whence a rough, callous, fistulous, cavernous, sinuous Ulcer, with luxation, fracture, &c.

With the Symptome, whence, a corroding, eating, painfull, sordid and virulent Ulcer.

With the cause and disease, With the cause and Symptome, With the disease and Symptome, With the cause, disease, and Symptome. } Examples whereof may be taken from that we have formerly delivered.

CHAP. II. Of the signs of Ulcers.

The signs of a putrid Ulcer.

Here are various signs of Ulcers according to their differences. For it is the sign of a putrid Ulcer, if it exhale a noysome, grievous, stinking and carion-like vapour, together with filthy matter. An eating Ulcer is known by the eating in, hollownesse and wearing away of the part wherein it resides, together with the adjoining parts. A sordid Ulcer may be known by the grosnesse and viscidty of the excrements it sends forth, and by the loose and spongy softnesse, or the crufted inequality of the flesh which grows over it. A cavernous Ulcer, by the straitnesse of the orifice, and largenesse and deepnesse of the windings within. A fistulous Ulcer, if to the last mentioned signs there accrew a callous hardnesse of the lips or sides of the Ulcer. A cancrus Ulcer is horrible to behold with the lips turned back, hard and swoln, flowing with virulent and stinking corruption, and sometimes also with bloody matter, together with the swelling and lifting up of the adjacent veins. An untemperate, or as they term it, a distempered Ulcer, is such as is nourished by some great distemper whether hot or cold, moist or dry, or compounded of these. An ill * natured or malign Ulcer is known by the difficulty of curing and rebellious contumacy to remedies appointed according to Art and reason. We know a catarrhus Ulcer, if the matter which feeds it flow to it from some varices thereunto adjoining, or dilated, swollen and broken veins, or from some entrail, or from the whole body being ill affected. An Apostumatous Ulcer is perceived by the presence of any tumor against nature, whose kind may be found out by sight and handling. Telephian Ulcers, are such as affected Telephus, and Chironian (in whose cure Chron excelled) are Ulcers which may be known by their magnitude not much putrid, and consequently not sending forth any ill smell, not eating, not tormenting with pain, but having their lips swoln and hard, and therefore ill to be healed. For although they may be sometimes cicatrized, yet it being but slender may easily be broken, and the Ulcer renewed. They are almost like an ulcerated Cancer, but that they are accompanied with swelling in the adjacent parts; they are also worse than these which are termed Cacoethe, that is, ill natured, or malign; whence it is that Fernelius thought they had a hidden cause of malignity, besides the common default of the humor, and that such as can scarce be driven away; such commonly are felt after the plague. Wherefore Galen thinks such to be malign as will not suppurate or yeeld any quittance.

Gal. cap. 5. lib. 4. Meth. * Ulcus caeothet.

Com. ad aphor. 22. sect. 5.

CHAP. III. Of the Prognosticks of Ulcers.

Aph. 45. sect. 6.

He bone must necessarily scale, and hollow scars be left by malign Ulcers of a years continuance or longer, and rebellious to medicins fitly applied. The bone must scale by reason of the continuall afflux, and wearing by the acrimony of the humor, which looses the composure and glue by which the parts thereof are joined together. But the scars must become hollow, for that the bone (whence all the flesh takes its first originall) or some portion thereof, being taken from under the flesh, as the foundation thereof, so much of the bulk of the flesh

flesh must necessarily sink down, as the magnitude of the portion of the wasted bone comes unto.

You may know that death is at hand, when the Ulcers that arise in or before diseases, are suddenly either livid or dried, or pale and withered. For such driness sheweth the defect of nature, which is not able to send the familiar and accustomed nutriment to the part ulcerated. But the livid or pale colour is not only an argument of the overabundance of cholera and melancholy, but also of the extinction of the native heat. In Ulcers where tumors appear, the patients suffer no convulsions, neither are frantick; for the tumor being in the habit of the body possessed with an Ulcer, argues that the nervous parts and their originall are free from the noxious humors. But these tumors suddenly vanishing and without manifest cause, as without application of a discutient medicin, or bleeding, those who have them on their backs have convulsions and distensions, for that the spine of the back is almost wholly nervous; but such as have them on their fore parts, become either frantick, or have a sharp pain of their side, or pleuritic, or else a dysentery if the tumors be reddish; for the forepart of the body is replenished and overspread with many and large vessels, into whose passages the morbid matter being translated, is presently carryed to these parts which are the seats of such diseases. Soft and loose tumors in Ulcers are good, for they shew a mildness and gentleness of the humors, but crude and hard swellings are naught; for all digestion in some measure resembles elixation. Ulcers which are smooth and shining are ill, for they shew that there resides an humor malign by its acrimony, which frets asunder the roots of the hairs, and depraves the naturall construction of the pores of the skin; whence it is that such as are troubled with Quartain agues, the Leprosie or *Lues venerea*, have their hair fall off. A livid flesh is ill in Ulcers which cause a rottenness or corruption of the bones lying under the flesh; for it is an argument of the dying heat and corruption of the bone, whence the flesh hath its originall & integrity.

These Ulcers which happen by occasion of any disease, as a Dropsie, are hard to be cured; as also those whereinto a *varix* or swollen vessel continually casts in matter; which a present distemper fosters; which have swollen, hard and callous lips; and such as are circular or round. An *Hypercarcosis*, or fleshy excrecence usually happens to Ulcers not diligently mundified; and if they possess the arms or Legs, they cause a Phlegmon or some other tumor in the groins, chiefly if the body be full of ill humors, as *Avicen* hath noted. For these parts by reason of their rarity and weakness are fit and subject to defluxions. *Albucazis* writes that for nine causes Ulcers are difficultly replenished with flesh and cicatrized. The first for want of blood, in a bloodlesse body; the second by reason of ill humors and the impurity of the blood; the third by the unfit application of unconvenient medicins; the fourth by reason of the sordidness of the Ulcer; the fifth by the putrefaction of the soft and carion-like flesh encompassing the Ulcer; the sixth when they take their originall from a common cause which every where rages with fury, such as are those which are left by the pestilence; the seventh by reason of the callous hardness of the lips of the Ulcer. The eighth when the heavens and air are of such condition as ministers fuell to the continuance of the Ulcer, as at Saragoza in Aragon; the ninth when the bones which lye under it are wasted by rottenness. An Ulcer that casts forth white, smooth, equall quittance, and little or no stinking, is easily healed; for it argues the victory of the native heat, and the integrity of the solid parts. We terme that smooth quittance which is absolutely concocted, neither yeelds any asperity to the touch, whereby we might suspect that as yet any portion of the humor remains crude; we call that equall wherein you can note no diversity of parts; & white not that which is perfectly so, but that which is of an ash colour, as *Galen* observes. But it is ill, if when the cure is indifferently forward, a flux of blood suddenly break forth in those Ulcers which beat strongly by reason of the great inflammation adjoynd therewith. For as *Hippocrates* observes, an effusion of blood happening upon a strong pulsation in Ulcers is evill; for the blood breaking out of an Artery cannot be stayed but by force; and also this blood is so furious by reason of the heat and inflammation the nourishers of this Ulcer that it breaks its receptacles, and hence ensues the extinction of the native heat, whence the defect of suppuration and a Gangrene ensues. Now for that there flowes two sorts of excrements from malign Ulcers, the more thin is termed *Ichor* or *sanies*, but the more grosse is named *sordes*; that is virulent and flowes from pricked nerves, and the *periosteum* when they are evill affected; but the other usually flowes from the Ulcers of the joints, and it is the worser if it be black, reddish, ash-coloured, if muddy or unequall like wine Lees, if it stink. *Sanies* is like the water wherein flesh hath been washed; it argues the preternaturall heat of the part, but when it is pale coloured, it is said to shew the extinction of the heat.

CHAP. IV. Of the Generall cure of Ulcers.

AN Ulcer is either simple or compound. A simple Ulcer, as an Ulcer hath one and that a simple indication, that is, exsiccation; and that more than in a wound, by how much an Ulcer is moister than a wound. There are many indications proposed for the cure of a compound Ulcer, in respect of which *Galen* would have us to keep this order, that we have the first regard of the most urgent, then of the cause, then of that, which unlesse it be taken away, the Ulcer cannot be healed. By giving you an example you may easily understand the meaning hereof. Imagin on the inside of the Leg a little above the ancle, an Ulcer very painfull, hollow, putrid, associated with the rottenness of the bone, circular, having hard and swollen Lips, and engirt with the inflammation and *varices* of the neighbouring parts. If you take this to cure, before you do any thing about the Ulcer, unlesse you be called upon by that which urges, as by vehemency of pain, you must first use generall means by calling and advising with a Physitian; For in *Galen*'s opinion, if the whole body require a preparation, then must that be done in the first place; for in some Ulcers purgation only will be sufficient; in some blood-letting; others are better by using both means, which is as the cause of the Ulcer proceeds from a

The curing of a simple Ulcer consists in exsiccation. *Gal. 7. Meth. cap. 12.*

Gal. lib. 4. de comp. med. secund. gen.

repletion

repletion or ilnesse of humors. Now by these means having taken away the cause of the Ulcer, you must come to the particular cure thereof, beginning with that which is most urgent. Wherefore you must first assuage the pain by application of things contrary to the cause thereof, as if it proceed from a Phlegmonous distemper, which hath long possesse, distended and hardened the part, it must be eased by evacuation. First, baching it with warm water, to mollifie and relax the skin, that so you may the more easily evacuate the contained humors; then shall you draw away portion of the matter causing the swelling and pain by scarification, if the Patient shall be of sufficient courage, or else by application of horse-leaches if he be more faint-hearted; and then you shall temper the heat thereof by applying *Unguentum refrigerans Galeni*. To conclude, you shall attempt all things which we have formerly delivered (in our treatise of Tumors) to take away the swelling thereof. When you have brought this to that passe you desire, you shall come to those which are such, that it cannot be taken away or healed without them, which shall be done by orderly helping the defects against nature which were conjoined with the Ulcer, to wit, the rottenesse of the bone, which you shall help by actuall cauteries; and in the mean while you shall draw the Ulcer into another form, to wit, cornered, and you shall cut away the callous hardnesse, and help the rottenesse. Then must you procure the falling away of the Eschar, and then provide for the scaling of the bone by the means formerly prescribed, lastly the mundified Ulcer must be filled with flesh. For generating of flesh two causes must concur, the efficient, and materiall; The efficient is, the good temper both of the whole body, as also of the Ulcerated part. For this prevailing, there will be an attraction, digestion, opposition and assimilation of the laudable juice to the part affected; verily the laudable temper is preserved by like things, but the vicious is amended by contraries. The matter to be spent upon flesh is laudable blood, which offends neither in quality, nor quantity. In this regeneration of the flesh there appear two kinds of excrements, the one more thin and humid called *Sanies*, the other more grosse termed *Sordes*. Both of these for that they are contrary to nature, do therefore hinder the regeneration of flesh, and therefore must be taken away by applying their contraries, as by things drying in the first degree, and more strongly or weakly detergent, according to the complexion of the part and the whole body, and the plenty and quality of the excrementitious humor, and the uncleanness of the Ulcer. For the part must be preserved by the use of the like, but the Ulcer overcome by application of things contrary thereto. After that by nature's endeavour and the Chirurgeons help the ulcer is replete with flesh, it must be cicatrized, that is, covered with a callous skin in stead of the true and native skin. It may be cicatrized by strewing of very drying powders having very little or no acrimony. Thus Alum and Vitrioll being burnt & made into powder, and thinly strewed upon the part do quickly cicatrize the former fleshy work. To this purpose also serve, the root of *Aristolochia*, Aloes, burnt Lead, Pomegranat pills burnt, Litharge, *Tutia*, and also plates of Lead besmeared with quicksilver, whose efficacy for this purpose Chirurgeons sometimes find more certain and powerfull than any other remedies.

cer.

Gal. lib. I.
simp. cap. 7.

Signs of a
hot distem-
pered ulcer.

Signs of a
cold di-
stempered
ulcer.

BEfore we speak of a distempered ulcer, it is meet, lest that the Chirurgeon take one distemper for another, briefly to relate the signs of each. You may know that an ulcer is associated with a dry distemper by your sight, as if the ulcer be as it were wrinkled, if it send forth little or no moisture; also it is known by touch, if it feel rough and hard. You shall correct this distemper by humecting medicins, as fomenting it with warm water according to *Galen's* opinion, or else with *Hydreleum* (i.) Oil and water mixt, but alwayes you must first purge, if the body shall abound with ill humors, or use Phlebotomie if the body be plethorick; otherwise you shall draw more humors into the part than it can bear. Now you shall so long foment it, untill the flesh which is about it begin to look red, wax soft and moist, and the part it self be a little swoln. If you proceed further, you will resolve all the humor which you have drawn thither, and so your labour is in vaine. After the fomentation apply such a remedy to the ulcerated part. *Rx. cremoris hordei ʒij. fol. malve in aq. coct. ʒj. pingued. porci ʒiʒ. mellis com. ʒʒ. misce in mortario & fiat unguentum.*

You shall know a moist distemper associates the ulcer by the plenty of the excrementitious humor, which the ulcer sends forth, by the spongy and fungous softnesse and growth of the flesh about it. You shall amend this by drying remedies, such as these are, which we term sarcoticks, having alwayes regard to the plenty of the humor, the proper temper of the part, and other indications formerly mentioned. Amongst other remedies *Galen* much commends Alum water, for it dries, clenfes and corroborates the affected part. Also this ensuing fomentation may be applied to good purpose. *Rx. rosar. rub. absinth. beton. tarsi barbati an. m. j. gallarum, nucum cupressi, an. ʒij. aluminis roche ʒj. fiat decoctio in vino austero, instituatursotus.* Then let *Empl. de verussa* or *De minio* be applied to the ulcer. Also I have found by experience that the powder of burnt alum lightly strewed upon the ulcer is very effectually in this case. You shall know that an hot distemper associates the ulcer by rednesse, or yellownesse thereof, by the heat manifest to your touch, and the propriety of your pain. Then must you have recourse to refrigerating things, such as *ung. Rosatum Mes. Refrigerans Gal. Populeon;* stoops and clothed dipped in Plantain water, Night-shade water, or Oxycrate. I have oft found by experience that scarification, or Leaches being applyed, did more conduce than any other remedy. For so the chafed blood, which by that means is apt to corrupt, is drawn away, and the part it self is also freed of that burden.

We know a cold distemper by the whitish or pale colour, by the touch of the Chirurgeon, and speech of the Patient complaining of the coldnesse of the ulcerated part. You shall correct this by applying and putting bottles filled with water about the part, or else swines bladders half filled with the following decoction. *Rx. origani, pulegii, chamæmeliloti, an. m. j. absinth. majorane, salvia, rorismar. an. m. ʒ. fiat. decoctio*

decoctio in vino generoso, addendo aque vitæ quod sufficit. Also the Ulcer may be conveniently fomented with sponges dipped in the same decoction, and let there be applyed thereto *Empl. Oxycroceum; emp. de meliloto; de Vigo cum mercurio, and sine mercurio.* But if a mixt and compound distemper be joined to the Ulcer, the Medicins must in like manner be mixt and compos'd. The residue of the Chirurgeons care and pains must be spent upon the proper and peculiar cure of the Ulcer, as it is an Ulcer; which we said in the former Chapter was contained in detersion, regenerating flesh and cicatrization thereof.

CHAP. VI. *Of an Ulcer with pain.*

Here oft-times so great pain accompanieth Ulcers, that it calls thereto the counsell of the Physitian. Wherefore if it proceed from any distemper, it shall be taken away by remedies proper against that distemper, such as we mentioned in the former Chapter. But if it do not so cease, we must go on to Narcoticks. Such are cataplasms of the leaves of Mandrakes, Water lillies, Henbane, Nightshade, Hemlock, the seeds of Poppy and oils of the same; to which also may be added *Opium, Populeon,* and other things of like faculties. But if a malign acrimony and virulency of an humor corroding and eating the flesh lying under it and the lips about it, cause and make the pain, you shall neither assuage it by anodynes, nor Narcoticks; for by application of gentle Medicins it will become worse and worse. Wherefore you must betake you to Cathæreticks; For strong Medicins are fittest for strong diseases. Wherefore let a pledget dipped in strong and more than ordinarily powerfull *Ægyptiacum,* or in a little oil of Vitriell, be applyed to the Ulcer; for these have power to tame this raging pain, and virulent humors. In the mean season let refrigerating things be put about the Ulcer, lest the vehemency of acrid Medicins cause a defluxion.

The matter of Narcotick cataplasms.

Cathæreticks have power to assuage pain.

CHAP. VII. *Of Ulcers with overgrowing or proudnesse of flesh.*

Ulcers have oft-times proud or overgrowing flesh in them, either by the negligence of the Chirurgeon, or fault of the Patient. Against this, drying and gently eating or consuming Medicins must be applyed; such as are Galls, *cortex thuris, Aloes, Tutia, Antimony, Pompholix, Vitrioll, Lead,* all of them burnt and washt if need require. Of these powders you may also make ointments with a little oil and wax; but if the proud flesh, as that which is hard and dense, yeeld not to these remedies, we must come to causticks, or else to iron, so to cut it off. For in *Galen's* opinion, the taking away of proud flesh is no work of nature, (as the generating, restoring and agglutinating of the flesh is) but it is performed by Medicins which dry vehemently, or else by the hand of the Chirurgeon; wherefore amongst the remedies fit for this operation, the powder of Mercury with some small quantity of burnt Alum, or burnt Vitriol alone, seem very effectually to me. Now for the hard and callous lips of the Ulcer, they must be mollified with Medicins which have such a faculty, as with Calves, Goose, Capons or Ducks grease, the oils of Lillies, sweet Almonds, Worms, Whelps, *Oesopus,* the mucilages of Marsh-mallows, Linseed, Fænugreek seed, Gum *Ammoniacum, Galbanum, Bdellium,* of which being mixed may be made Emplaisters, unguents, and liniments: or you shall use *Empl. Diachylon, or de Mucilagibus, De Vigo cum mercurio.* To conclude, after we have for some few dayes used such like remedies, you may apply to the Ulcer a plate of Lead rubbed over with Quicksilver; for this is very effectually to smooth an Ulcer and depreesse the lips: if you shall prevail nothing by this means, you must come to the causticks, by which if you still prevail nothing, for that the lips of the Ulcer are so callous that the causticks cannot pierce into them, you must cleave them with a gentle scarification, or else cut them to the quick, so to make way, or as it were open a window for the Medicin to enter in, according to *Galen.* Neither in the interim must you omit *Hippocrates* his advice, which is, that by the same operation we reduce the Ulcer if round, into another figure, to wit, long or triangular.

Things waiting superfluous flesh.

Lib. 3. Meth. cap. 6.

For the callous lips of Ulcers.

Lib. 4. Meth. cap. 2.

CHAP. VIII. *Of an Ulcer putrid and breeding Worms.*

Wounds are divers times bred in ulcers, whence they are called wormy ulcers; the cause hereof is the too great excrementitious humidity prepared to putrefie by unnaturall and immoderate heat. Which happens, either for that the ulcer is neglected, or else by reason of the distemper and depraved humors of all the body, or the affected part; or else for that the excrementitious humor collected in the ulcer, hath not open and free passage forth; as it happens to the ulcers of the ears, nose, fundament, neck of the womb, and lastly, to all sinuous & cuniculous ulcers. Yet it doth not necessarily follow that all putrid ulcers must have worms in them; as you may perceive by the definition of a putrid ulcer which we gave you before. For the cure of such ulcers after generall means, the worms must first be taken forth, then the excrementitious humor must be drawn away, whence they take their originall. Therefore you shall foment the ulcer with the ensuing decoction, which is of force to kill them; for if any labour to take forth all that are quick he will be much deceived; for they oft times do so tenaciously adhere to the ulcerated part, that you cannot pluck them away without much force and pain. *Rx. absinth. centaur. majoris, marrubii, an. M. j. fiat decoctio ad lb. ss. in qua dissolve aloes ʒ β. unguenti ægyptiaci ʒ j.* Let the ulcer be fomented and washed with this Medicin, and let pledgets dipped herein be put into the ulcer; or else if the ulcer be cuniculous or full of windings, make injection therewith which may go into all parts thereof.

The cause of worms breeding in Ulcers.

A fomentation to kill the worms.

Achigenes much commends this following Medicin. *Rx. Ceruse polii montani, an. ʒ β. picis navalis liquide Gs. l. a. comp. quantum sufficit, misce in mortario pro linimento.* If the putrefaction be such that these Medicins will not suffice for the amendment thereof, you must come to more powerfull, or to cauteries also, or hot Irons, or

to section; yet you must still begin with the more gentle, such as this of *Galens* description. *R. ceræ, ℥ij. cerusæ ℥j. olei ros. ℥ij. salis ammon. ℥ss. squamæ eris ℥ij. thur. alum. erug. malicor. calcis vivæ, an. ℥j. fiat emplastrum.* Or *R. terebinth. lotæ ℥ij. ceræ albæ ℥ss. liquefiant simul addendo sublimati, ℥ss. salis torrefacti, & vitrioli calcinati, an. ℥j. fiat mundificativum.* Or you must use our *Ægyptiacum* alone, which hath Sublimate entering into the composition thereof; but in the interim the circuit of the Ulcer must be defended with refrigerating and defensative things for fear of pain.

CHAP. IX. Of a sordid Ulcer.

A Sordid Ulcer after the cure of the body in generall, shall be healed with detergent medicins; the indication being drawn from the grosse and tough excrement, which with the excrementitious *sanies*, as it were besieging, and blocking up the ulcerated parts, weakens and as it were dulls the force of medicins though powerfull, which causeth us to begin the cure with fomentations and lotions, as thus. *R. Lixivii com. ℥b. j. absinth. marrub. apii, centaur. utriusque, hypericonis, an. M. ss. coquantur, colaturæ, quæ sufficiat, adde mellis rosati ℥j. unguenti ægyptiaci ℥ss. fiat fotus.* Then use the following deterfive medicin: *R. succi apii, & plantag. an. ℥ij. mellis com. ℥j. terebinth. ℥ss. pul. Ircos Florent. & aloes an. ℥ss. fiat medicamentum.* The Chirurgeon must well consider, at how many dressings he shall be able to wash away the grosse *sordes* or filth sticking close to the Ulcer, and dry up the excrementitious *sanies*. For oftentimes these things may be done at one dressing; but in others who have more quick sense or feeling, not so soon. But when the Ulcer is freed of such grosse *Sordes* or filth, you must forbear to use more acrid things for fear of pain, defluxion, inflammation, and erosion, whereby the Ulcer would become more hollow. Wherefore then we shall be content to apply remedies which dry and cleanse without acrimony that we may so help natures indeavours in generating flesh. Such remedies are the pouders of Aloes, Mastich, Myrrh, Orris, Litharge, Antimony, roots of Gentian, Barly flower, and the like, which being strewed upon the Ulcer, you shall cover it with Lint, and put over that a plate of Lead, rubbed over with quicksilver; and you shall put on these deterfives and desiccatives more or lesse strong, as you shall find it requisite and necessary. For the too plentiful use of drying and deterfive things, doth in time hollow the Ulcers, whereby it comes to passe that in short time in like sort, a greater quantity of *Sanies* flows from the Ulcer, the proper substance of the flesh being dissolved by the force or acrimony of deterfive medicin; as also the proper alimentary humor, which flowed to the part, being in the like sort, a greater quantity of *Sanies* flowed from the Ulcer, the proper substance of the flesh being dissolved by the force or acrimony of the deterfive medicine, as also the proper alimentary humor, which flowed to the part, being in like sort defiled: which thing beguiles the unskillfull Chirurgeon. For by how much he sees the Ulcer flow more plentifully with *Sanies*, he endeavours by so much the more to exhaust and dry up with more acrid medicins these humidities as if they were excrementitious; But *Galen* hath long ago admonished us to take heed hereof, setting forth a History of a certain Emperick who dressing a sordid Ulcer with a green, acrid and eating medicin, dissolved the flesh, and so consequently made the Ulcer more hollow, and caused more pain and defluxion; whereby it happened that continually adding more acrid medicins, he continually by his ignorance and unskillfulness increased the colliquation of the flesh, the largeness of the ulcer and excrementitious humidity. Wherefore we must take speciall care whether the sordid Ulcer grow each day worse, by its proper fault and the impurity of the whole body besides, or else by the colliquation of the flesh and corruption of the benign and alimentary humor sent thither for the nutrition of the part, by the too frequent and unskillful use of too acrid a medicin. You may conjecture this by the increase of the pain without reason, and by the heat and redness of the lips of the Ulcer. Therefore you must principally have regard to this, that you give each of your Patients his fit measure, that is, a convenient and agreeable medicin to each of their strengths, taking indication from the strength, distemper, and consistence of the whole body and affected part; for there is a great deal of difference whether you apply a medicin to a plowman or labourer, or to an Eunuch and woman, or whether to the Leg, or eyes. For these medicins which to a dense and hard body and part are only detergent and drying, the same are to delicate and tender bodies and parts cathæretick and eating, by colliquation of the flesh, and corruption of the nourishment, making an increase of *Sordes* or filth; on the contrary those things which do laudably and sufficiently cleanse the flesh in a soft body and dry up the *Sanies*, these same things applied to a hard body encrease the *Sordes* and *Sanies* by suffering them to breed, neither are they of sufficient power to wash away the tenacious impurity of a dense body. Wherefore the skillfull Chirurgeon will see when he must betake himself from too strongly cleansing and eating medicins, to these which are more milde.

CHAP. X. Of a virulent, eating and malign Ulcer which is tearmed Cacoethes, and of a Chironian Ulcer.

Virulent and eating Ulcers differ not unlesse in *magis* and *minus*, for we tearm it a virulent Ulcer, which sends forth a virulent *sanies*, which is properly called *Virus*. This *Virus*, or virulency, when it becomes more malign, gnawes and feeds upon the parts which lye under, and are adjoining to the Ulcer, and makes an eating Ulcer. Such Ulcers are by *Galen* called *Dyssepulotica*, that is, difficultly to be cicatrized; for, saith he, it happens that the Ulcer is *Dyssepulotick*, either for that the part affected may be vitiated either in the habit or temper thereof, so that it may corrupt the humor which flows thither; such an Ulcer is by a particular name tearmed *Cacoethes*; or for that by reason of the evill quality of the blood flowing thither and eating the part, the part affected being too moist cannot heal up. He further adds that a Chironian

ulcer is far more malign than these Ulcers which are termed *Cacoethe*. For the cure; by reason that all these Ulcers have a large extent, for some are more malign and ill to be cicatrized than othersome; it is also necessary to have divers medicins ready and at hand distinct both in their faculties and the degrees thereof, so that it is no marvail if they oft fail of their purpose, who with the same medicin dresse and think they shall heale all malign Ulcers. This following medicin described by *Aesclepiades* is much commended by *Galen*. *R. squame aris, eruginis, rase, an. ℥ij. cere lb. β. resinae laricis. ℥ij. β. quæ liquari possunt aridis affundantur,* and make an emplaister to be laid only upon the Ulcer; for you must lay a defensative about the Ulcer for fear of inflammation. But *Galen* saith that the following Epulotick of *Primion* excels the rest, as that which to desperate Ulcers (which many have taken in hand and left as incurable,) was of certain and approved use. *R. soreos ℥ij. aluminis scissilis, calcis vine, an. ℥ij. thuris gallarum, an. ℥iiij. cere lb. j. & ℥iiij. sevi vitulini lb. j. & ℥vij. olei veteris quantum sufficit, fiat emplastrum.*

CHAP. XI. An advertisement to the young Chirurgion touching the distance of times wherein malign Ulcers are to be dressed.

O shew the use of *Aesclepiades* his medicins described in the former Chapter, and convince the error of these Chirurgions, who think they do well for their Patients, if they twice or thrice on a day dresse malign ulcers; I have here thought good to digresse a little from my purpose and to interpose *Galens* authority. Rightly (saith *Galen*) hath *Aesclepiades* added these words to the formerly described medicin: And loose this after three dayes, and foment the ulcer, and fasten the same emplaister being washed, and apply it again; for unlesse the medicin adhere long to the skin, it will do no good. Which thing notwithstanding many Physicians have been ignorant of, thinking if they wiped away the sanies from the ulcer thrice on a day, they should do better than those who did the same but twice a day. But those who dresse it but once a day, are reproved by the Patients as negligent. But they are much mistaken; for you must remember, as we have delivered in most of our writings, that the qualities of all neighbouring bodies do mutual actuate and affect each other in some degree, although the one thereof be much more powerfull; for by this reason in space of time they become somewhat alike, though they otherwise differ much; But when the quality of the medicin shall be like the species to the body to be cured, there follows the better successe. Wherefore he which moved by these reasons first appointed to use the emplaister formerly applyed, is worthy of commendations; and we ought to follow him much the rather, seeing that which he found out by reason, is approved by experience. Neither did he unadvisedly command to foment the wound every third day, that is, every dressing; for seeing it is a powerfull medicin, therefore it stands in need of mitigation. Thus much *Galen*, whose opinion grounded on reason, he can again confirm with another reason. It is already sufficiently known, that medicins can do nothing in us unlesse by the force of the native heat, which stirs up the faculty of the medicin to operation. But in ulcers which are absolutely malign, the native heat of the affected part is very languid, being broken and debilitated by the presence of the preternaturall heat; so that it stands in need of a great space of time to actuate the vertue and faculty of the medicin. Wherefore, if in that time, when as the native heat hath much moved and stirred up the faculty of the medicin, the ulcer be loosed or opened, and that emplaister cast away which was laid upon the part, and a fresh one laid in stead thereof; the heat implanted in the part is either dissipated by the contact of the air, or is weakened and driven in; and that endeavour which was made by the emplaister was to no purpose, being as it were stopped in the midst of the course. But a new emplaister being laid on, the heat of the part must undergo a new labour, so to stir up the faculty to bring it to act.

Gal. lib. 4.
de comp. med.
see Gen.
Cap. 5.

Galens reason further explained.

For all medicins are, what they are, in faculty. Equall to this is their error, who by too oft renewing their emplaisters on the same day; do too powerfully clense; for so they do not only take away the excrementitious humors, both *sordes* and *sanies*, but also the alimentary juice; to wit, the *Rob*, *Cambium*, and *Gluten*, which are the next matter for procreating of laudible flesh. Wherefore it is not good to dresse ulcers so often in one day, and to loose them to apply new emplaisters, unlesse some greivous symptome (as pain) force us to do it, which requires to be asswaged and mitigated by the often changing and renewing of Anodyne medicins.

Medicins are only such in faculty.

CHAP. XII. How to bind up Ulcers.

Or the binding up of ulcers, you must alwayes begin your bandage at the ulcer. Now the Rowler must be so large that it may not only cover and comprehend the ulcer, but also some portion of the adjacent parts above and below; and let it presse the ulcer with that moderation, that it may only presse out the excrementitious humors. For so the ulcer will become dry, and consequently more neer to healing, as it is observed by *Hippocrates*. Let this be the measure of your binding, that it be neither too strait for hence would ensue pain and defluxion; nor too lax, for such is of no use. You may moisten your boulders and Rowlers in oxycrate or in red and astringent wine, especially in Summer; when you have bound it up the part must be kept quiet. For according to *Hippocrates*, those who have an ulcer in the leg, ought neither to stand, nor sit, but to lye on a bed. Wherefore when the legs are ulcerated the arms must be exercised, by handling, lifting up and casting downe of divers things. But on the contrary if the arms be ulcerated, the legs must be exercised with walking, or frictions from above downwards, if the Patient cannot endure to walk. So the humors and spirits which with more violence and greater plenty run down to the part affected, may be drawn back and diverted.

The beginning of your binding must be at the Ulcer.

Hip. lib. de ali.

Revulsion into contrary parts.

CHAP. XIII. Of the cure of particular ulcers, and first of those of the eyes.

4. Meib.

or that (in Galens opinion) the divers indication in curing diseases is drawn from the condition of the part, to wit, the temper, complexion, site, figure, use, dull or quick sense; Therefore having briefly handled the generall cure both of simple and compound and implicit ulcers, I think it fit to treat of them now as they are distinguished by the parts, beginning with these of the eyes. These according to *Celsus*, are sometimes caused by pustules, or a sharp defluxion which frets or eats in funder the coats thereof, or else by a stroak.

Lib. 5. cap. 6. lib. 3. Botryon. Celoma. Argemon. Epicauma. The cure.

A Collyrium to

cleanse the ulcers of the eyes.

A Sarcotick Collyrium.

An Epulotick Collyrium.

Lib. 6. cap. 6.

A Collyrium for hollow scars. The scars of the Horny coat are white, and these of the Adapted.

Paulus sets down these differences of the ulcers of the eyes; If (saith he) a small, little and hollow ulcer be upon the horny coat, it is by the Greeks termed *Botryon*; but if it be broader and lesse deep, it is termed *Celoma*; about the circle of the *Iris* or Rainbow, it is called *Argemon*. If it be crusty and sordid, it is termed *Epicauma*. These in generall require the same cure as the former, that is, to be mundified, incarnated, dried and cicatrized; but the part affected indicates more gentle medicins. Wherefore having purged the Patient and taken some blood both from his arm, as also from his veins and temporall Arteries, and bathed him if it be needfull; to divert the defluxion you shall to his shoulders apply cupping glasses with scarification; or else bread newly drawn out of the oven, and sprinkled with *aqua vite* or some good wine shall be applyed to the originall of the spinall marrow. But you shall apply to the forehead and temples an astringent emplaster made of *emplastrum contra rupturan, ung. Comitissa*, and *resiccativum rubrum* mixed together. But this ensuing *Collyrium* described by *Celsus* and approved by *Höllerius*, shall be dropped into the eye. *R. æris usti, cadmiæ ustæ & lotæ, an. ʒij. ex aqua fingatur collyrium quod liquore ovi dissolvatur*. But in the mean time you must diligently observe whether you put the eye to any great pain. Wherefore now and then by putting anodyne medicins thereto, it will be good to comfort it. Also you may make *collyria* of the decoction of Plantain, *sænugreek*, wormwood, with a little quantity of Sugar-candy, *tutra*, gum *tragacanth*, myrrh and vitrioll dissolved therein. When the ulcer is mundified, the following sarcotick will be of good use. *R. sarcocollæ in lacte muliebri nutritæ, ʒiij. pul. diaireos simplicis, gum. arabici, tragacanth. an. ʒʒ. mucilaginis sænugræci quantum sufficit ut inde fiat collyrium*. But you must note that for moist ulcers, powders are more convenient than *Collyria*. When the ulcer is plained or filled with its proper flesh, it may be cicatrized with the following *collyrium*. *R. tutiæ, cadmiæ ut decet preparatæ, cerusæ, antimonii, olibani, an. ʒʒ. myrrhæ, sarcocollæ, sanguinis Draconis, aloes, opii, an. ʒʒ. cum aqua plantaginis fiat collyrium*; or the powder only may be conveniently strewed thereon.

Celsus hath noted that the cicatrizing of the eyes is incident to two dangers, that is, lest they be too hollow, or else too thick. If too hollow, they must be filled by the following remedy, *R. Papaveris lachrymæ, ʒʒ. jagapeni, popanacis, an. ʒʒ. aruginis ʒj. cumini ʒiij. pipëris ʒij. cadmiæ lotæ & cerusæ, an. ʒʒʒ. cum aqua pluviali fiat collyrium*. But if the scars be thick or grosse, the following remedy will extenuate them. *R. cinamon. acaciæ, an. ʒʒ. cadmiæ elotæ, croci, myrrhæ, papaveris lachrymæ, gum. arabici, an. ʒj. pipëris albi, thuris, an. ʒʒ. æris combusti, ʒiij. cum aqua pluviali fiat collyrium*. But if the scar be upon the cornea or horny coat, so that it cover the pupilla or sight, the sight will be intercepted by the denseness of the membrane. Here you must also observe, that the scars that are on the Cornea are white, but these on the Adnata are red, because this is spread over with more little veins than that.

CHAP. XIII. Of the Ozæna and Ulcers of the Nose.

Lib. 6. cap. 8. Gal. lib. 3. de comp. med. secund. locos cap. 3. The cure.

He *Ozæna* is a deep and stinking ulcer in the inside of the nose, sending forth many crusty and stinking excrementions. *Celsus* saith that such ulcers can scarcely be healed. It is caused (as *Galén* saith) by the distillation of acrid and putrid humors from the head into the nostrills about the mammillary processes. For the cure, the Patient must eat sparingly, and his meat must neither be sharp nor strong; the humor being prepared must be purged, the head dried and strengthened, that so it may neither admit the excrementitious humors, nor send them down; then must we come to the part affected with the ulcer. The ulcer must be dried with a repelling medicine, such as is the juice of Pomegranats boiled to the half in a brasse vessell; the powder of Calamint, Cresses, white Hellebore, the juice of Cresses with Alum and other things which you may read in *Celsus*. *Galén* out of *Archigenes* wishes, to draw up into the nostrills the juice of Calamint, or that the Calamint it self being dried, and made into powder, may be blown with a quill into the nose. Others use this following powder. *R. ros. rub. mint. calam. arom. rad. angelicæ, gentian. macis, cariop. an. ʒʒ. camph. ambre, an. gr. iij. mosch. gr. vj. fiat pulvis subtilissimus*. *Marardus* writes that the Urine of an Ass, though a nasty medicine, is an excellent remedy in this affect. But if the inveterate and contumacious evill do not yeeld to these remedies, then you must have recourse to Coprose, Verdigreec, *sal ammoniacum*, and Alum with Vinegar. It divers times happens that the ulcer spreading on, comes to take hold of the *Ossa ethmoidea* or five-like bones; in which case you must not forcibly pluck them out, but refer the whole business to nature, and expect when they shall come away of themselves, making in the mean while injections into the nostrills of *aqua vite*, wherein Cephalick powders have been steeped for the greater drying.

Lib. 20. epist. 5. An injection when the Ozæna shall come to the Ossa Ethmoidea.

CHAP. XV. Of the Ulcers of the mouth.

Aph. 24. sect. 3. Celsus lib. 6. cap. 11. Gal. com. ad 3. lib. epidem.

Of this tribe are the *Aphthæ*, ulcers familiar to little children, according to *Hippocrates*. They oft-times begin at the gums, and by the palat of the mouth creep into the uvula, throtle, and over all the mouth, as *Celsus* saith. *Galén* makes two kinds of *Aphthæ*'s; the one of easie cure, such as that which usually troubles children by reason of the acrimony of the nurses milk; the other is malign by reason of an afflux of an evill humor (that is, venerated and malign) into the mouth.

mouth. For the cure, it shall be good to abstain from all acrid things, and if it be a sucking child, it will not be amiss to temper the nurses milk with refrigerating meats, bathing the whole body, and fomenting the dugs with warm water; for all the members in children are most tender, and as it were mucous, and their mouths are unaccustomed to meats and drinks. For topick medicins, you must make choice of such which may quickly and readily work the effect; for here the condition of the affected part is such, that they cannot long remain and adhere thereto. Therefore if the ulcer be malign, it must be lightly touched with *aqua fortis* which hath been used in separating metalls and which besides is tempered with six parts of common water. You may for the same purpose use the oils of Vitrioll, Sulphur, Antimony, Mercury water and the like. *Aetius* wishes you to touch and correct such ulcers with a lock of wooll dipped in scalding oil, and so fastned to the end of a probe, untill they wax white and become smooth or plain. For so their eating and spreading force will at length be bridled, and laudable flesh grow up in place of that which is eaten. After such burning it will be good to wash the mouth with the following gargarism, which also of its self alone will serve to cure Aphtha's, which are not malign. *Rx hordei integri p. j. plantag. ceterach. piloselle. agrimonie. an. M. j. fiat decoctio ad lb. j. in qua dissolve mel- lis rosati ʒj. dianoron. ʒʒ. fiat gargarisma.* You may also make other gargles, of Pomegranate pills, Balau- sties, Sumach, Berberies, red roses being boyled, and dissolving in the strained liquor *Dianoron* and *Dianucum* with a little Alum. For *Galen* writes, that simple ulcers of the mouth are healed with things which dry with moderation; now *Dianoron* and *Dianucum* are such. But others stand in need of strong medicins, with such like. If the palat be seized upon, we must use the more diligence and care; for there is danger, lest being the part is hot and moist, the bone which lyes under which is rare and hu- mide, may be corrupted by the contagion and fall away, and the voice or speech be spoiled. If the ulcer be pocky, omitting the common remedies of ulcers, you must speedily betake your self to the proper antidote of that disease, to wit, quick-silver. Fistulous ulcers often take hold on the Gums, whence the root of the next tooth becomes rotten, and so far that the acrimony of the *Sanies* oft-times makes its self a passage forth on the outside under the chin; which thing puts many into a false conceit of the *scrophule* or Kings evill, and consequently of an incurable disease. In such a case *Aetius*, and *Celsus* counsell is, to take out the rotten tooth, for so the *Fistula* will be taken away, the Gum pressing and thrusting its self into the place of the tooth which was taken forth; and so the cause nourishing the putrefaction being taken away, (that is, the tooth) the rest of the cure will be more easy. The ulcers of the tongue may be cured by the same remedies by which the rest of the mouth; yet those which breed on the side thereof endure very long, and you must look whether or no there be not some sharp tooth over against it, which will not suffer the ulcer in that place to heal; which if there be, then must you take it away with a file.

The cure.
A gargarism for the Aphthæ. Lib. 6. meth. Cap. 10. Ulcers of the palat must be quickly and carefully dressed. *Aetius* Lib. 6. cap. 3. *Celsus* lib. 6. cap. 13.

CHAP. XVI. Of the Ulcers of the Ears.

Ulcers are bred in the auditory passage both by an externall cause, as a stroak, or fall, as also by an internall, as an abscess there generated. They oft-times flow with much matter, not there generated, for such ulcers are usually but small and besides in a spermatick part, but for that the brain doth that way disburden its self.

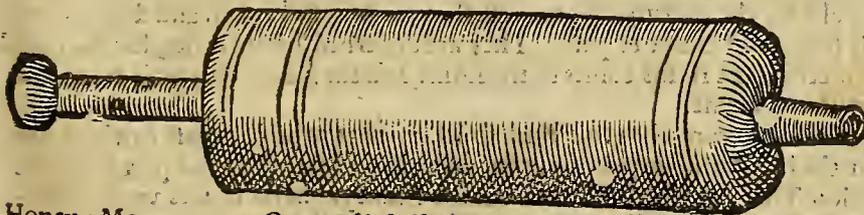

Their cau- ses.

For the cure, the chief regard must be had of the antecedent cause, which feeds the ulcer, and it must be diverted by purging medicins, Masticatories, and Errhines. This is the form of a Masticatory. *Rx Mastich. ʒj. staphi sagr. & pyreth. an. ʒj. cinam. & caryoph. an. ʒʒ. fiant Masticatoria, utatur mane & vesperi.* But this is the form of an Errhin: *Rx succi betonic. mercurial. & melissæ, an. ʒʒ. vini albi ʒj. misce & frequenter naribus attrahatur.* For topick medicins we must shun all fatty and oily things, as *Galen* set down in *Method. medendi*, where he finds fault with a certain follower of *Thessalus* who by using *Tetrapharmacum*, made the ulcer in the ear grow each day more filthy, than other, which *Galen* healed with the *Trochisces* of *Andronius* dissolved in Vinegar, whose composure is as followeth. *Rx balauft. ʒij. alumin. ʒj. atrament. ʒator. ʒij. myrthe ʒj. thur. aristoloch. gallarum, an. ʒij. salis Ammon. ʒj. excipiantur omnia melicrato, & fiant trochisci.*

Honey: Moreover an Oxes gall dissolved in strong Vinegar, and dropped in warm, amends and dries up the putrefaction wherewith these ulcers flow. Also the scales of Iron made into powder boyled in sharp Vinegar, dried and strewed upon them. But if the straitness of the passages should not give leave to the matter contained in the windings of the ears to passe forth, then must it be drawn out with an In- strument thereupon called a *Pyoulcus*, or matter-drawer, whereof this is the figure.

CHAP. XVII. Of the ulcers of the windpipe, weazon, stomach and Guts.

These parts are ulcerated either by an externall cause, as an acrid medicine, or poyson swal- lowed down; or by an internall cause, as a malign fretting humor which may equall the force of poyson generated in the body, and restrained in these parts. If the pain be increased by swallowing or breathing, it is the sign of an ulcer in the weazon, or windpipe joining there- to. But the pain is most sensibly felt when as that which is swallowed is either sour or acrid, or the

The Cau- ses. Signs.

air breathed in, is more hot or cold than ordinary. But if the cause of pain lye fastned in the stomach, more grievous symptomes urge; for sometimes they swoond, have a nauseous disposition and vomiting, convulsions, gnawings, and pain almost intolerable, & the coldness of the extreame parts; all which when present at once, few scape unless such as are young, and have very strong bodies. The same affect may befall the whole stomach, but because both for the bitterness of pain, and greatness of danger, that ulcer is far more grievous which takes hold of the mouth of the Ventricle, honoured by the Ancients with the name of the Heart; therefore Physitians do not make so great a reckoning of that which happens in the lower part of the stomach. Now we know that the Guts are ulcerated if Pus, or much purulent matter come forth by stool; if blood come that way with much griping; for by the Pus staying and as it were gathered together in that place, there is as it were a certain continuall *Tenesmus*, or desire to goe to stool. Now all such ulcers are cured by meats and drinks, rather than by medicins, according to *Galen*. Therefore you must make choice of all such meats and drinks as are gentle, and have a lenitive faculty, shunning acrid things; for *Tutia*, *Lytharge*, *Ceruse*, *Verdigreece* & the like, have no place here, as they have in other ulcers. But when as the ulcer shall be in the Gullet or Weazon, you must have a care that such things may have some viscosity or toughnesse, and be swallowed by little and little, and at divers times; otherwise they will not much avail, because they cannot make any stay, in these commune wayes of breath and meat; therefore they presently slip down and flow away; wherefore all such things shall be used in form of an *Eglegma*, to be taken lying on the back, and swallowed down by little and little, opening the muscles of the throat, lest the medicin passing down suddainly and in great quantity, cause a cough, a thing exceeding hurtfull to these kinds of ulcers. When they must be clenfed, you shall have crude honey, which hath a singular faculty, above all other detergent things, in these kind of ulcers. But when they can conveniently swallow, you shall mix Gum *Tragacanth* dissolved in some astringent decoction. In ulcers of the stomach all acrid things (as I have formerly advised) must be shunned, as those which may cause pain, inflammation and vomit, and besides hinder the digestion of the meat. Therefore let them frequently use a ptisan, and sugred gellyes wherein gum *Tragacanth*, and bole *Armenick* have been put, the decoction of *Prunes*, *Dates*, *Figs*, *Raisons*, *Honey*, *Cowes milk* boyled with the yolks of eggs, and a little common honey. When they are to be agglutinated, it will be convenient to make use of austere, astringent, and agglutinative things which want all acrimony, and ungratefull tast, such as are *Hypocistis*, *Pomegranate flowres* and pills, *terra sigillata*, *sumach*, *acacia*, a decoction of quinces, the *Lentisk wood*, the tops of *Vines*, of *brambles*, *myrtles*, made in astringent wine, unlesse there be feare of inflammation. Their drink shall be *Hydromel* water with *Sugar*, *syrup of Violets* and *Iujubes*. Honey mixed with other medicins is a very fitting remedy for ulcers of the guts and other parts, more remote from the stomach; for if you shall use astringent medicins alone of themselves, they will stick to the stomach; neither will they carry their strength any further; but honey mixed with them, besides that it distributes them to the rest of the body, and helps them forwards to the affected parts, also clenfes the ulcers themselves. Here also *Asses milk* may with good success be used in stead of *Goats* or *Cowes milk*. The use of a vulnerary potion is also commendable, if so be that it be made of such hearbes and simples, as by a certain tacit familiarity have respect to the parts affected. But the ulcers of the Guts have this difference amongst themselves; that if the greater guts be affected, you may heal them with a *Clyster* and injections, made also sharp to correct the putrefaction; such as are those which are made of *Barly water*, or wine with *Aegyptiacum*. But if the small guts be ulcerated, they must be rather healed by potions and other things taken at the mouth, for that (as *Galen* saith) these things which are put up into the body by the *Fundament*, do not commonly ascend to the small or slender guts, but such as are taken at the mouth cannot come unlesse with the losse of their faculty, so far as the great guts.

CHAP. XVIII. Of the Ulcers of the Kidneys and Bladder.

Causes.

Signes.

Ulcers are caused in the Kidneys and Bladder, either by the use of acrid meats, drinks, or medicins, as *Cantharides*; or else by the collection of an acrid humor bred in that place, sent or falln thither; or else by the rupture of some vessell, or an abscesse broken and degenerated into an ulcer, as it sometimes comes to passe. They are discerned by their site, for the pain and heavinesse of ulcers of the Reins comes to the Loins, and the Pus or matter is evacuated well and thoroughly mixed with the Urine.

Hip Aphor. 81. sect. 4.
Aphor. 76. sect. 4.
Aphor. 77. sect. 4.

Neither doth the Pus which flows from the reins stink so ill, as that which is cast forth of the bladder; the reason is, for that the bladder being a bloodlesse, fleshlesse and membranous part, hath not such power to resist putrefaction. That Pus which flows from the Kidneys never flows without water; and although by long keeping in an Urinall, it at length subsides or falls to the bottome, and may be seen separated; yet when it is first made, you may see it perfectly mixed with the Urine; but that Pus which flows from the bladder is oftentimes made alone without Urine; and usually it comes to passe that the Pus, or matter which flows from the ulcerated Kidneys, hath in it certain caruncles, or as it were haire, according to the rule of *Hippocrates*. Those who in a thick Urine have little caruncles, and as it were hairs come forth together therewith, they come from their Kidneys; but on the contrary those who have certain bran-like scales come from them in a thick Urine, their bladder is scabby or troubled with a scabby ulcer.

The cure.
Why we must shun strong purges.

For the cure; it is expedient that the belly be soluble either by nature or Art, and the use of mollifying Clysters. And it is good to vomit sometimes, so to draw back the humors by whose conflux into the affected part the ulcer might be fed and made more sordid and filthy. You must beware of strong purgations, lest the humors being moved and too much agitated, the matter fit to nourish the ulcer

Ulcer may fall down upon the kidneys or bladder. The ensuing potion is very effectually to mundifie those kind of Ulcers. *Rx. Hordei integri, M.ij. glycyrrhizæ ras. & contus. ℥β. rad. acetosæ & petrosel. an. ℥vj. fiat decoctio ad lb. j. in colatura dissolve mellis dispens. ℥ij.* Let him take every morning the quantity of four ounces. *Gordonius* exceedingly commends the following Trochisces. *Rx. quatuor sem. frig. maj. mundatorum, sem. papaveris albi, sem. malvæ, portul. cydon. baccarum myrti, tragacanth. gum. arab. nucum pinearum mund. pistach. glycyrrhizæ mund. mucaginis sem. psilii, amygd. dulc. hordei mund. an. ℥ij. bol. armeni. sang. drac. spodi. rosarum. myrrhæ, an. ℥β. excipiantur hydromelite, & fingantur trochisci singuli ponderis ℥ij.* Let him take one thereof in the morning dissolved in Barley water or Goats milk. *Galen* bids to mixe honey and diuretick things with medicines made for the Ulcers of the reins and bladder, for that they gently move urine, and are as vehicles to carry the medicines to the part affected. Ulcers of the bladder are either in the bottome thereof, or at the neck and urinary passage. If they be in the bottome, the pain is almost continuall; if in the neck, the pain then pricks and is most terrible when they make water and presently after. The ulcer which is in the bottome sends forth certain scaly or skinny excrements together with the urine; but that which is in the neck, causes almost a continuall *Tentigo*. Those which are in the bottome are for the most part incurable, both by reason of the bloodless and nervous nature of the part, as also for that the ulcer is continually chased and troubled by the acrimony of the urine, so that it can hardly be cicatrized. For even after making of water some reliques of the urine alwayes remain in the bottome of the bladder, which could not therefore pass forth together with the rest of the urine, for that for the passing forth of the urine, the bladder being distended before, falls and is complicated in its selfe. Ulcers of the bladder are healed with the same medicins as those of the reins are; but these not only taken by the mouth but also injected by the urinary passage. These injections may be made of *Gordonius* his Trochisces formerly prescribed, being dissolved in some convenient liquor; but because ulcers of the bladder cause greater and more sharpe pain than those of the kidneys, therefore the Chirurgeon must be more diligent in using Anodynes. For this purpose, I have often by experience found, that the oil of henbane made by expression gives certain help. He shall do the same with Cataplasms and liniments applyed to the parts about the *Pecten* and all the lower belly and *perineum*, as also by casting in of Clysters. If that they stink, it will not be amiss to make injection of a litle *Ægyptiacum* dissolved in wine, plantain, or rose water. For I have often used this remedy in such a case with very prosperous success.

Signs to know what part of the bladder is ulcerated. Why ulcers in the bottome of the bladder are incurable.

Ægyptiacum for the ulcers of the bladder.

CHAP. XIX. Of the Ulcers of the Womb.

Ulcers are bred in the womb either by the conflux of an acrid, or biting humour; fretting the coats thereof, or by a tumour against nature degenerating into an absesse, or by a difficult and hard labour; they are known by pain at the *perineum*, and the efflux of *Pus* and *Sanies* by the privity. All of them in the opinion of *Avicen* are either putrid, when as the *Sanies* breaking forth is of a stinking smell, and in colour resembles the water wherein flesh hath been washed; or else sordid, when as they flow with many virulent and crude humours; or else are eating or spreading ulcers, when as they cast forth black *Sanies*; and have pulsation joined with much paine. Besides they differ amongst themselves in site, for either they possess the neck and are known by the sight, by putting in a *speculum*, or else are in the bottome, and are manifested by the condition of the more liquid and serous excrements, and the site of the pain. They are cured with the same remedies wherewith the ulcers of the mouth, to wit, with *aqua fortis*, the oil of Vitriol and Antimony, and other things made somewhat more milde, and corrected with that moderation, that the ulcerated parts of the Womb may be safely touched with them; it is requisite that the remedies which are applyed to the ulcers of the womb, do in a moment that which is expected of them, for they cannot long adhere or stick in the womb, as neither to the mouth. *Galen* saith that very drying medicins are exceeding fit for the ulcers of the womb, that so the putrefaction may be hindred or restrained, whereto this part as being hot and moist is very subject; besides that the whole body unto this part as unto a sink sends downe its excrements. If an ulcer take hold of the bottome of the womb, it shall be cleansed and the part also strengthened by making this following injection. *Rx. hordei integri p. ij. guajaci. ℥j. rad. Ireos. ℥β. absinth. plant. centaur. utriusque, an. M. j. fiat decoct. in aqua fabrerum ad lb. ij. in quibus dissolve mellis rosati, & syrupi de absinthio, an. ℥ij. fiat injectio.* For amending the stinking smell I have often had certaine experience of this ensuing remedy. *Rx. vini rub. lb. j. unguent. egyptiaci ℥ij. bulliant parum.* Thus the putrefaction may be corrected, and the painfull malicioufness of the humour abated. Ulcers when they are cleansed must presently be cicatrized; that may be done with Alum water, the water of Plantain wherein a litle Vitriol or Alum have been dissolved. Lastly, if remedies nothing availing, the ulcer turn into a *cancer*, it must be dressed with anodynes and remedies proper for a *cancer*, which you may finde set down in the proper treatise of *Cancers*. The cure of ulcers of the fundament was to be joined to the cure of these of the womb; but I have thought good to referre it to the treatise of *Fistula's*, as I do the cure of these of the urinary passage to the treatise of the *Lues venerea*.

Why strongly drying things are good for ulcers of the womb. An injection for an ulcer in the bottome of the womb. An injection hindring putrefaction.

CHAP. XX. Of the Varices and their cure by cutting.

Varix is the dilatation of a vein, some whiles of one and that a simple branch, other whiles of many. Every *varix* is either streight or crooked, and as it were infolded into certaine windings within its selfe. Many parts are subject to *Varices*, as the temples, the region of the belly under the navill, the testicles, womb, fundament, but principally the thighs and legs. The matter of them is usually melancholy bloud, for *Varices* often grow in men of a melancholy temper, and which usually feed on gross meats, or such as breed gross and melancholy humours. Also women with child are commonly troubled with them, by reason of the heaping together of their suppressed mensuall evacuation.

What a *Varix* is, and what be the differences thereof. The matter.

The causes. The precedent causes are a vehement concussion of the body, leaping, running, a painful journey on foot, a fall, the carrying of a heavy burden, torture or racking. This kind of disease gives manifest signs thereof by the largeness, thickness, swelling and colour of the veins. It is best not to meddle with such as are inveterate; for of such being cured there is to be feared a reflux of the melancholly blood to the noble parts, whence there may be imminent danger of malign ulcers, a cancer, madness or suffocation. When as many *Varices* and diversly implicit are in the legs, they often swell with congealed and dried blood, and cause pain which is increased by going and compression. Such like *varices* are to be opened by dividing the veine with a Lancet, and then the blood must be pressed out, and evacuated by pressing it upwards and downwards; which I have oft-times done, and that with happy success to the Patients, whom I have made to rest for some few dayes, and have applyed convenient medicins. A *varix* is often cut in the inside of the leg a little below the knee, in which place commonly the originall thereof is seen. He which goes about to intercept a *varix* downwards from the first originall and as it were fountain thereof, makes the cure far more difficult. For hence it is divided as it were into many rivulets, all which the Chirurgeon is forced to follow.

The cure.

The cutting of *Varices*.

For what intention a *Varix* must be cut.

Paulus cap. 82. lib. 6.

The manner how to cut it.

A *varix* is therefore cut or taken away so to intercept the passage of the blood and humours mixed together therewith, flowing to an ulcer seated beneath, or else lest that by the too great quantity of blood, the vessel should be broken, and death be occasioned by a hæmorrhagic proceeding from thence. Now this is the manner of cutting it. Let the Patient lye upon his back on a bench or table, then make a ligature upon the leg in two places the distance of some four fingers each from other, wherein the excision may be made, for so the vein will swell up and come more in sight, and besides you may also mark it with inke; then taking the skin up between your fingers cut it long wayes according as you have marked it, then free the bared vein from the adjacent bodies, and put thereunder a blunt pointed needle (lest you prick the vein) thred with a long double thred, and so bind it fast; and then let it be opened with a Lancet in the middle under the ligature just as you open a vein, and draw as much therehence as shall be fit. Then straight make a ligature in the lower part of the forementioned vein, and then cut away as much of the said vein as is convenient between the ligatures, and so let the ends thereof withdraw themselves into the flesh above and below, let these ligatures alone untill such time as they fall away of themselves. The operation being performed, let an astringent medicine be applyed to the wound and the neighbouring parts; neither must you stir the wound any more for the space of three dayes. Then do all other things as are fit to be done to other such affects.

CHAP. XXI. Of Fistula's.

What a Fistula is.

Fistula is a sinuous, white, narrow, callous, and not seldome unperceivable ulcer. It took its denomination from the similitude of a reeden (Fistula) that is, a pipe, like whose hollownes it is. A Fistula is bred in sundry parts of the body, and commonly followes upon abscesses or ulcers not well cured.

What a Callosus is.

The differences of Fistula's.

A *Callosus* is a certain fleshy substance, white, solid, or dense and hard, dry and without pain, generated by heaping up of dried excrementitious phlegme, or else adust melancholy encompassing the circuit of the ulcer, and substituting it selfe into the place of laudable flesh. The *Sinus* or cavity of a Fistula is sometimes dry, and other while drops with continuall moisture: sometimes the dropping of the matter so-dainly ceases, and the orifice thereof is shut up, that so it may deceive both the Chirurgeon and the Patient with a false shew of an absolute cure; for within a while after it will open again and run as formerly it did. Some Fistula's are bred by the corruption of a bone, others of a nerve, others of membranes, and others of other parts of the body. Some run straight in, others and that the greater part, have turnings and windings; some have one, others have more orifices and windings, some are at the joints, others penetrate into some capacity of the body, as into the chest, belly, guts, womb, bladder; some are easily, others difficultly cured, and some wholly incurable. There are divers signs of Fistula's according to the variety of the parts they possess; for if that which you touch with the end of your probe make resistance, and rebound, then you may know that it is come to the bone, and then if the end of the probe slip up and down as on a smooth and polite superficies, it is a sign that the bone is yet sound, but if it stop and stay in any place as in a rough way, then know that the bone is eaten, rough and perished, sometimes the bone lies bare, and then you need not use the probe. Besides also it is a sign that the bone is affected, if there be a purulent efflux of an unctuous or oily matter, not much unlike that marrow wherewith the bone is nourished. For every excrement shewes the condition of the nourishment of the part whence it is sent; in a Fistula which penetrates to a nerve, the Patient is troubled with a pricking paine, especially when you come to search with a probe, especially if the matter which flowes down be more acrid. Oft-times if it be cold, the member is stupified the motion being weakened; besides also the matter which flowes from thence is more subtle, and somewhat like unto that which flowes from the bones, yet not oily nor fat, but sanious and viscous, resembling the condition of the alimentary humour of the nerves. The same usually appears and happens in Fistula's which penetrate to the Tendons and those membranes which involve the muscles. If the Fistula be within the flesh, the matter flowing thence is more thick and plentiful, smooth, white, and equall. If it descend into the veins or arteries, the same happen as in those of the nerves, but that there is no such great pain in searching with your probe, nor no offence or impediment in the use of any member: yet if the matter of the fistulous ulcer be so acrid, as that it corrode the vessels, blood will flow forth; and that more thick if it be from a vein, but more subtle and with some murmuring if from an artery. Old Fistula's and such as have run for many years, if suddainly shut up, cause death; especially in an ancient and weak body.

The signes.

The signe that the bone is bare from the condition of the matter which is cast forth.

Aerius 117. 4. sect. 2. cap. 55.

Old Fistula's if closed prove mortall.

CHAP. XXII. Of the cure of Fistula's.

FOr the cure; in the first place it will be expedient to search the Fistula; and that either with a wax size, a probe of lead, gold or silver, to find out the depth and windings or corners thereof. But if the Fistula be hollowed with two or more orifices, and those cuniculous, so that you cannot possibly and certainly search or find them all out with your probe; then must you cast an injection into some one of these holes, and so observe the places where it comes forth, for so you may learn how many, and how deep or superficially cavities there be; then by making incisions you must lay open and cut away the callous parts. You must make incisions with an incision knife or razor, or else apply actually or potentially canteries; for nature cannot unless the callous substance be first taken away, restore or generate flesh or agglutinate the distant bodies. For hard things cannot grow together, unless by the interposition of glue, such as is laudable blood; but a callous body on all sides possessing the surface of the ulcerated flesh, hinders the flowing of the blood out of the capillary veins for the restoring of the lost substance and uniting of the disjoined parts. If you at any time make caustick injections into the Fistula, you must presently stop the orifice thereof, that so they may have time to worke the effect, for which they are intended. Which thing we may conjecture by the tumor of the part, the digesture of the flowing matter, and its lesser quantity. Then you must hasten the falling away of the Eschar, and then the ulcer must be dressed like other ulcers. But oft-times the *Callous* which possesses the sinuous cavity of a Fistula, overcome by the power of acrid and escarotick medicins comes whole forth, and falls out like a pipe, and so leaves a pure ulcer underneath it. Which I observed in a certain Gentleman, when I had washed with strong *Aegyptiacum* divers times a Fistulous ulcer in his thigh shot through with a bullet; then presently by putting in my Balsam formerly described, he grew well in a short time. Fistula's which are neer great vessels, Nerves or principall intrailles, must not be meddled with unless with great caution. When a Fistula proceeds by the fault of a corrupt bone, it is to be considered whether that fault in your bone be superficially, or deeper in, or whether it is wholly rotten and perished. For if the default be superficially it may easily be taken away with a desquamatory Trepan; but if it penetrate even to the marrow, it must be taken forth with cutting mallets, first having made way with a *Terebellum*. But if the bone be quite rotten and perished, it must be wholly taken away, which may be fitly done, in the joints of the fingers, the *radius* of the Cubit and Leg; but no such thing may be attempted in the socket of the Huckle bone, the head of the Thigh bone, or any of the Rack bones when they are mortified, neither in those Fistula's, which are of their own nature incurable; but you shall think you have discharged your duty and done sufficiently for the Patient, if you leave it with a prognostick. Of this nature are Fistula's which penetrate even to the bowells, which come into the parts overspread with large vessels or Nerves, which happen to effeminate and tender persons, who had rather dye by much, then to suffer the pain and torment of the operation. Like caution must be used, when by the cutting of a Fistula there is fear of greater danger, as of convulsion if the disease be in a nervous part. In these and the like cases the Chirurgion shall not set upon the perfect cure of the disease, but shall think it better to prevent by all means possible that the disease by fresh supplies become no worse, which may be done if he prevent the falling down of any new defluxion into the part; if by an artificiall diet he have a care that excrementitious humors be not too plentifully generated in the body; or so order it, that being generated they may be evacuated at certain times, or else diverted from the more noble to the base parts. But in the mean space it shall be requisite to wast the faulty flesh, which growes up more then is fitting in the ulcer, and to cleanse the *sordes* or filth, with medicins, which may do it without biting or acrimony and putrefaction.

How to find out the windings and cavities of Fistula's.

Caustick injections.

Celsus lib. 5.

Remedies for a Fistula proceeding from a corrupt bone.

The cure of what Fistula's may be attempted, and which may not. A palliative cure of a Fistula.

CHAP. XXIII. Of the Fistula's in the Fundament.

Fistula's in the Fundament are bred of the same causes as other kinds of Fistula's are; to wit, of a wound or absesse not well cured, or of a hemorrhoid which is suppurated. Such as are occult, may be known by dropping down of the *sanions* and purulent humor by the Fundament and the pain of the adjacent parts. But such as are manifest by the help of your probe you may find whither they goe and how far they reach. For this purpose the Chirurgion shall put his finger into the Fundament of the Patient, and then put a Leaden probe into the orifice of the Fistula, which if it come to the finger without interposition of any *medium*, it is a sign it penetrates into the capacity of the Gut. Besides also then there flowes not only by the Fundament but also by the orifice which the malign humor hath opened by its acrimony, much matter, somewhiles sanious, and oft-times also breeding Worms. Fistula's may be judged cuniculous, and running into many turnings and windings, if the probe do not enter far in, and yet notwithstanding more matter flowes thence then reason requires should proceed from so small an ulcer. You may in the orifices of all Fistula's, perceive a certain callous wart, which the common Chirurgions tearm a *Hens arse*. Many symptomes accompany Fistula's which are in the Fundament, as a *Tenesmus*, strangury and falling down of the Fundament. If the Fistula must be cured by manuell operation, let the Patient lye so upon his back, that lifting up his legs, his thighs may presse his belly, then let the Chirurgion, having his nail pared, put his finger besmeared with some ointment into the Patients Fundament; then let him thrust in at the orifice of the Fistula a thick Leaden needle drawing after it a thread consisting of thread and horse hairs woven together, and then with his finger taking hold thereof and somewhat crooking it, draw it forth at the Fundament, together with the end of the Thread. Then let him knit the two ends of the thread with a draw or loose knot, that so he may straiten them at his pleasure.

The causes.

Signs.

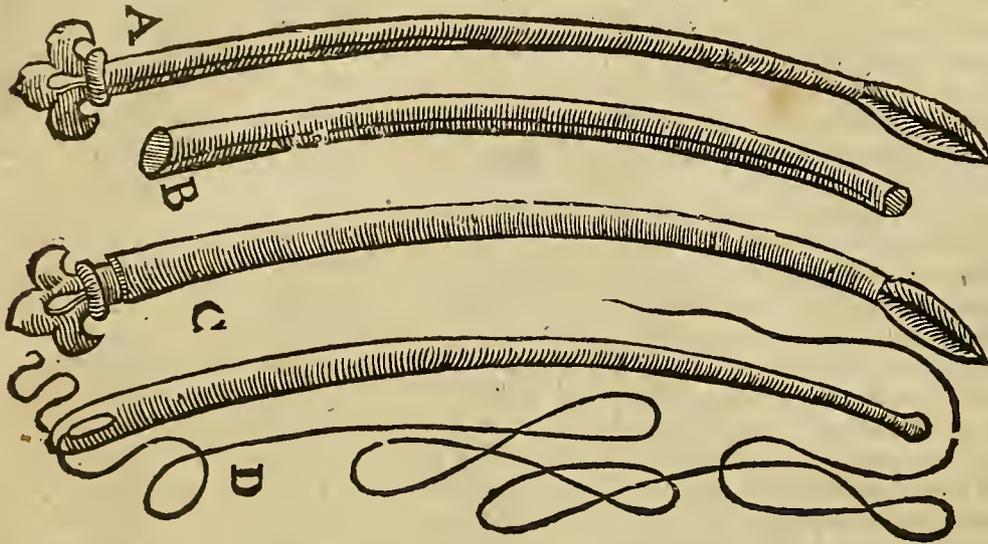

Symptomes.

The art of binding and cutting a Fistula of the Fundament.

But

But before you bind them you shall draw the thread somewhat roughly towards you as though you meant to saw the flesh therein contained, that you may by this means cut the Fistula without any fear of an Hæmorrhage, or flux of blood. It sometimes happens that such Fistula's penetrate not into the Gut; so that the finger by interposition of some callous body cannot meet with the needle or probe. Then it is convenient to put in a hollow Iron or silver probe so through the cavity thereof to thrust a sharp pointed needle, & that by pricking and cutting may destroy the *Callus*; which thing you cannot perform with the formerly described leaden probe, which hath a blunt point, unless with great pain.

The description of a hollow silver Probe to be used with a needle, as also a Leaden Probe.

A. Shewes the Needle.

B. The hollow probe.

C. The needle with the probe.

D. The Leaden needle drawing a thread after it.

The *Callus* being wasted, the Fistula shall be bound as we formerly mentioned. That which is superficial needs no binding, onely it must be cut with a crooked scal-

prum, and the *Callus* being consumed, the rest of the cure must be performed after the manner of other ulcers. But you must note, that if any parcell of the *Callous* body remain untoucht by the medicin or Instrument, the Fistula reviving again will cause a relapse.

CHAP. XXIII. Of Hæmorrhoides.

Hæmorrhoides, as the word is usually taken, are tumors at the extremitities of the veins encompassing the Fundament, caused by the defluxion of an humor commonly melancholick, and representing a certain kind of *Varices*. Some of these run at an hole being opened, which sometimes in space of time contracts a *Callus*; others only swell, and cast forth no moisture;

some are manifest; other lye only hid within. Those which run, commonly cast forth blood mixed with yellowish serous moisture, which stimulates the blood to break forth, and by its acrimony opens the mouths of the veins. But such as do not run, are either like blisters, such as happen in burnis, and by practitioners are usually called *vesicales*, and are caused by the defluxion of a phlegmatick and serous humor; or else represent a Grape, whence they are called *Vvales*, generated by the afflux of blood laudable in quality, but overabundant in quantity; or else they expresse the manner of a disease, whence they are termed *morales*, proceeding from the suppression of melancholick blood; or else they represent warts, whence they are stiled *Verrucales*, enjoying the same materiall cause of the generation as the *morales* do.

This affect is cause of many accidents in men; for the perpetuall efflux of blood extinguisheth the vivid and lively colour of the face, calls on a dropsie, overthrowes the strength of the whole body. The flux of Hæmorrhoides is commonly every moneth, sometimes only foure times in a yeare. Great pain, inflammation, an Abscesse which may at length end in a Fistula, unlesse it be resisted by convenient remedies, do oft-times forerun the evacuation of the Hæmorrhoides. But if the Hæmorrhoides flow in a moderate quantity, if the Patients brook it well, they ought not to be stayed, for that they free the Patients from the fear of imminent evils, as melancholy, leprosie, strangury and the like. Besides, if they be stopped without a cause, they by their reflux into the Lungs cause their inflammation, or else break the vessells thereof, and by flowing to the Liver cause a dropsie by the suffocation of the native heat; they cause a dropsie; and universall leanness on the contrary, if they flow immoderately, by refrigerating the Liver by losse of too much blood; wherefore when as they flow too immoderately, they must be stayed with a pledget of haire down dipped in the ensuing medicin.

Rx pul. aloes, thuris, balaust. sang. draconis, an. ʒʒ. incorporentur simul cum ovi albumine; fiat medicamentum ad usum. When they are stretched out and swoln without bleeding, it is convenient to beat an Onion roasted in the embers with an Oxes gall; and apply this medicin to the swoln places, and renew it every five houres. This kind of remedy is very prevalent for internall Hæmorrhoides; but such as are manifest may be opened with horseleaches, or a Lancet. The juice or masse of the hearb called commonly Dead-nettle or Arkangell, applyed to the swoln Hæmorrhoides opens them, and makes the congealed blood flow thence. The *Fungus* and *Thymus* being diseases about the fundament are cured by the same remedy. If acrimony, heat and pain do too cruelly afflict the Patient, you must make him enter into a bath, and presently after apply to the ulcers (if any such be) this following remedy. *Rx Olei ros. ʒiiij. ceruse ʒi. Litharg. ʒʒ. cera nova, ʒvj. opii ʒj. fiat unguent. secundum artem.* Or else, *Rx thuris, myrrhæ, croci, an. ʒj. opii ʒj. fiat unguentum cum oleo rosarum & mucagine sem. psillii, addendo vitellum minus ovi.* You may easily prosecute the residue of the cure according to the generall rules of Art.

OF BANDAGES, OR, LIGATURES.

THE FOURTEENTH. BOOK.

CHAP. I. *Of the differences of Bandages.*

Bandages, wherewith we use to bind, do much differ amongst themselves. But their differences (in Galens opinion) are chiefly drawn from six things; to wit, their matter, figure, length, breadth, making, and parts whereof they consist. Now the matter of Bandages is threefold; Membranous or of skins, which is accommodated peculiarly to the fractured grilles of the Nose; of Woollen, proper to inflamed parts, as those which have need of no astringency; of Linnen, as when any thing is to be fast bound: and of Linnen cloaths, some are made of flax, other some of hemp, as Hippocrates observes. But Bandages do thus differ amongst themselves in structure, for that some thereof consist of that matter which is sufficiently close and strong of it self, such are the membranous; others are woven, as the linnen ones. But that linnen is to be made choice of for this use, and judged the best, not which is new and never formerly used, but that which hath already been worn and served for other uses; that so the Bandages made thereof may be the more soft and pliable: yet must they be of such strength, that they may not break with stretching, & that they may straitly contain & repell the humor ready to flow down, and so hinder it from entering the part. These, besides, must not be hemmed nor stitched, must have no lace nor seam; for hems and seams by their hardness presse into, and hurt the flesh that lyes under them. Lace, whether in the midst or edges of the rowler, makes the Ligature unequal. For the Member where it is touched with the lace, as that which will not yeeld, is pressed more hard; but with the cloth in the middle more gently, as that which is more lax. Furthermore, these Ligatures must be of clean cloth, that if occasion be, they may be moistened or steeped in liquor appropriate to the disease, and that they may not corrupt, or make worse that liquor by their moistening therein. Now the Bandages which are made of Linnen clothes must be cut long-ways, and not athwart, for so they shall keep more firm and strong that which they bind, and besides, they will be alwaies alike, and not broader in one place then in another. But they thus differ in figure, for that some of them are rowled up, to which nothing must be sowed, for that they ought to be of a due length to bind up the member: others are cut or divided, which truly consist of one piece, but that divided in the end (such are usually taken to bind up the breasts) or else in the midst; others are sowed together, which consist of many branches sowed together, and ending in divers heads, and representing divers figures, such are the Bandages appropriated to the head. But they thus differ in length, for that some of them are shorter, others longer: so in like sort for breadth; for some are broader, others narrower. Yet we cannot certainly define nor set down neither the length, nor breadth of Rowlers, for that they must be various, according to the different length and thickness of the members or parts. Generally they ought both in length and breadth to fit the parts, whereunto they are used. For these parts require a binding different each from other, the head, the neck, shoulders, arms, breasts, groins, testicles, fundament, hips, thighs, legs, feet and toes. For the parts of Bandages, we term one part their body, another their heads. By the body we mean their due length and breadth; but their ends, whether they run long-ways or a-crosse, we according to Galen, term them their heads.

CHAP. II. *Sheweth the indications and generall precepts of fitting of Bandages and Ligatures.*

Here are, in Hippocrates opinion, two indications of fitting Bandages or Ligatures; the one whereof is taken from the part affected; the other from the affect it self. From the part affected, so the leg, if you at any time bind it up, must be bound long-ways, for if you bind it overthwart, the binding will loosen as soon as the Patient begins to go, and put forth his leg, for then the muscles take upon them another figure. On the contrary the Arm or Elbow must be bound up, bending in and turned to the breast, for otherwise at the first bending, if it be bound when it is stretched forth, the Ligature will be slacked, for that (as we formerly said) the figure of the muscles is perverted. Now for this indication, let each one perswade himself thus much, that the part must be bound up in that figure, wherein we would have it remain.

Now for that indication which is drawn from the disease, if there be a hollow ulcer, sinuous and cuniculous, casting forth great store of Sanies, then must you begin the ligature and binding from the bottom of the sinus, and end at the orifice of the ulcer; and this precept must you alwaies observe, whether the sinus be sealed in the top, bottom, middle, or sides of the ulcer. For thus the filth therein contained shall be emptied and cast forth, and the lips of the ulcer too far separated, shall be joined together: otherwise the contained filth will eat into all that lyes near it, increase the ulcer, and make it

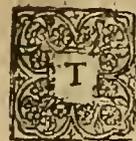

uncurable by rotting the bones which lye under it with this acrid *sanies* or filth. But some Ligatures are remedies of themselves, as those which perform their duties of themselves, and whereto the cure is committed, as are these which restore their native unitie, those parts which are disjoined: others are not used for their own sakes, but only to serve to hold fast such medicins as have a curative facultie. This kind of Ligature is either yet a doing, and is termed by *Hippocrates* *Deligatio operans*; or else done and finished, and is called, *Deligatio operata*: for the first, that the Ligature may be well made, it is fit that it be close rowled together, and besides, that the Surgeon hold it stiffe and strait in his hand, and not carelessly, for so he shall bind up the member the better. Also he must in the binding observe, that the ends of the Rowler, and consequently their fastning may not fall to be on the affected or grieved part, for it is better that they come above or below, or else on the side: besides also, he must have a specciall care that there be no knot tyed upon the same place, or upon the region of the back, buttocks, sides, joints, or back part of the head, or to conclude in any other part upon which the Patient uses to lean, rest or lye. Also on that part where we intend to sow or fasten the Rowlers, you must double in their ends, that so the fastning or future may be the stronger, otherwise how close soever they shall be wrapped or rowled about the member, yet will they not remain firm, especially if they be of a great breadth. For the second kind of Ligature, to wit, that which is already done and finished; the Surgeon, the performer thereof, must consider to what end it was done, and whether he hath performed it well and fitly, as also neatly and elegantly, to the satisfaction both of himself and the beholders. For it is the part of a skilfull Workman every where handsomely and rightly to perform that which may so be done.

In fractures and luxations and all dislocations of bones, as also in wounds and contusions, you must begin your bandage with two or three windings or wraps about upon the place, and that (if you can) more straitly than in other places, that so the set bones may be the better kept in their places, and that the humors, if any be already fallen thither, may by this strait compression be pressed forth, as also to hinder and prevent the entrance in of any other which may be ready to fall down. But in fractures (as those which never happen without contusion) the blood flowes, and is pressed forth of its proper vessels, as those which are violently battered and torn, which causes fugillation in the neighbouring flesh, which first looks red, but afterwards black and blue by reason of the corruption of the blood poured forth under the skin. Wherefore after these first windings, which I formerly mentioned, you must continue your rowling a great way from the broken or luxated part; he which does otherwise, will more and more draw the blood and humors into the affected part, and cause *Impossumes*, and other malign accidents. Now the blood which flowes, goes but one way downwards, but that which is pressed is carryed as it were in two paths, to wit, from above downwards, and from below upwards. Yet you must have a care that you rather drive it back into the body and bowels, then towards the extremities thereof, as being parts which are incapable of so much matter, and not furnished with sufficient strength to suffer that burden, which threatens to fall upon it, without danger and the increase of prenaturall accidents. But when this masse and burden of humors is thrust back into the body, it is then ruled and kept from doing harm by the strength and benefit of the faculties remaining in the bowels and the native heat.

CHAP. III. Of the three kinds of Bandages necessary in fractures.

Two sorts of Ligatures are principally necessary for the Surgeon, according to *Hippocrates*, by which the bones aswell broken as dislocated may be held firm when they are restored to their naturall place.

Of these some are called *Hypodesmides*, that is, Under-binders: others, *Epidesmides*, that is, Over-binders. There are sometimes but two under-binders used, but more commonly three. The first must first of all be cast over the fracture, and wrapped there some three or foure times about, then the Surgeon must mark and observe the figure of the fracture; for as that shall be, so must he vary the manner of his binding. For the Ligature must be drawn strait upon the side opposite to that whereto the luxation or fracture most inclines, that so the bone which stands forth may be forced into its seat, and so forced may be the more firmly there contained. Therefore if the right side be the more prominent or standing forth, thence must you begin your ligation, and so draw your ligature to the left side. On the contrary, if the left side be more prominent, beginning there, you shall goe towards the opposite side in binding and rowling it. Here therefore would I require a Surgeon to be *Ambidexter*, (i. e.) having both his hands at command, that so he may the more exquisitely perform such variety of ligations. But let him in rowling, bend or move this first ligature upwards, that is, towards the body, for the former reasons. But neither is this manner of ligation peculiar to fractures, but common to them with luxations: for, into what part soever the luxated bone flew, then when it is restored, that side must be bound the more loosely and gently whence it departed, and that on the contrary more hard unto which it went. Therefore the ligature must be drawn from the side whereunto the bone went; so that on this side it be more loose and soft, and not straitly pressed with boulders or rowlers, that so it may be more inclined to the side opposite to the luxation. If the ligation be otherwise performed, it succeeds not well, for the part is relaxed, and moved out of its natural seat; wherefore there will be no small danger, lest the bone be forced out again, and removed from its place, whereinto it was restored by art and the hand. Which thing *Hippocrates* so much feared, that on the contrary he willed that the set bone should be drawn somewhat more unto the part contrary to that whereunto it was driven by force, than the naturall and proper site thereof should require. But to return to our former discourse of the three Ligatures: The first underbinder being put on, we then take the second, with which we in like sort begin at the fracture, but having wrapped it once or twice about

Hip. cers. 4. Sed. 2. offic. Initio 2. fist. aff.

Ligatures must not be only lightly, but also nearly performed.

Gal. eor. 1. sent. 25. sect. 1. lib. de fract.

Sent. 24. sed. 2. offic. e.

Hypodesmides.

about there, for that, as we formerly said, we must not force back, and presse so much blood towards the extremities, as we must do towards the body and bowels. Wherefore this Ligature shall be drawn from above downwards, gently straining it to presse forth the blood contained in the wounded part: When by rowling you shall come to the end of the part, then you shall carry back again that which remains thereof, to wit, upwards; But otherwise you may take the third under-binder, wherewith you may begin to rowle, whereas you left with the second, & you may carry it thus, rowling it from below upwards. These under-bindings thus finished, apply your boulders, after them your over or upper-bindings, which are oft-times two, but sometimes three. The first hath two heads, and is wrapped both from the right hand and the left, for the preservation of the first under-binder and the boulders, and restoring the muscles to their native figure. The two other which remain, consist of one head, and the one of them must be rowled from below upwards, the other from above downwards, after such a manner, that they may be directly contrary to the under-binders; as if they were rowled from the right hand, then these must be from the left. Now this is the manner of *Hippocrates* his Ligation, which, for that it is now grown out of use, we must here set down that which is in common use. They do not at this time use any over-binders, but that which we termed the third under-binder serves our Surgeons in stead of the three forementioned over-binders. Wherefore they carry this third under-binder, wrapped from below upwards (as we formerly said) contrary to the first and second under-binder, as if these begun on the right side, this shall be rowled from the left, and shall end whereas the first under-binder ended. And you must not only draw it indifferently hard, but also make the spires and windings more rare. This third rowler is of this use in this manner of Ligation, that is, it restores the muscles to their native figure, from whence they were somewhat altered by the drawing and rowling of the two former Ligatures. But you must always have regard, that you observe that measure in wrapping your Ligatures, which reason, with the sense of the Patient, and ease in suffering, prescribes; having regard that the tumor become not inflamed. Also the habit of the body ought to prescribe a measure in Ligation: for tender bodies cannot away with so hard binding as hard. Verily, in fractures and luxations, the humors by too strait binding are pressed into the extreme parts of the body; whence grievous and oft-times enormous Oedema's proceed; for healing whereof the Ligature must be loosed, and then the tumified parts pressed by a new rowling, which must be performed from below upwards, and so, by forcing the matter of the tumor thither, it may be helped; for there is no other hope or way to drive the humor back again. He which doth this, forsakes the proper cure of the disease, so to resist the symptome, which the Surgeon shall never refuse to do, as often as any necessary cause shall require it. For this cause *Hippocrates* bids, that the bandages be loosed every three dayes, and then to foment the part with hot water, that so the humors, which (drawne thither by the vehemency of pain) have settled in the part, may be dissolved and dispersed; and itching and other such like symptomes prevented. The fear of all accidents being past, let the Ligation be sooner or later loosed, and more slacked then it formerly was accustomed; that so the blood and laudable matter, whereof a *Calum* may ensue, may flow more freely to the affected part.

When the third under-binder is necessary. *Epidemi.*

The manner of binding now in use.

What mean to be observed in wrapping the Ligatures.

Why *Hippoc.* bids to loose the Ligatures every third day.

CHAP. III. Of the binding up of Fractures associated with a wound.

IT sometimes happens, that a Fracture is associated by a wound, and yet for all this it is fit to bind the part with a Ligature, otherwise there will be no small danger of swelling, inflammation, and other ill accidents, by reason of the too plentiful afflux of humors from the neighbouring parts. But it is not fit to endeavour to use that kind of binding which is performed with many circumvolutions or wrappings about. For seeing the wound must be dressed every day, the part must each day necessarily be stirred, and the Ligature, consisting of so many windings, loosed; which thing will cause pain, and consequently hinder the knitting and uniting which is performed by rest. Therefore this kind of binding may be performed by one only rowling about the wound, and that with a rowler which consists of a twice or thrice doubled cloth, made in manner of a boulder, and sewed with as much conveniency as you can, that it may be so large as to encompass and cover all the wound, for these reasons, which shall be delivered at large in our Treatise of Fractures. But if the wound run long-ways, let the boulders and splints be applied to the sides of the wound, that so the lips of the wound may be pressed together, and the contained filth pressed forth. But if it be made overthwart, we must abtain from boulders and splints: for that, in *Galen's* opinion, they would dilate the wound, and the purulent matter would be pressed out, and cast back into the wound.

How to bind up a Fracture with a wound.

Ad sent. 12. sect. de fract.

CHAP. V. Certain common precepts of the binding up of Fractures and luxations.

IN every Fracture and Luxation, the depressed, hollow and extenuated parts, such as are neer unto the joints, ought to be filled up with boulders, or clothes put about them, so to make the part equall; that so they may be equally and on every side pressed by the splints, and the bones more firmly contained in their seats. So when the knee is bound up, you must fill the ham or that cavity which is there, that so the ligation may be the better and speedilier performed. The same must be done under the arm-pits, above the heel, in the arm neer the wrist; and, to conclude, in all other parts which have a conspicuous inequality by reason of some manifest cavities. When you have finished your binding, then enquire of the Patient, whether the member seem not to be bound too strait. For if he say, that he is unable to endure it so hard bound, then must the binding be somewhat slackned. For, too strait binding causes pain, heat, defluxion, a gangrene, and lastly, a sphacell or mortification: but too loose is unprofitable, for that it doth not contain the parts in that state we desire. It is a sign of a just ligation, that is neither too strait nor too loose, if the ensuing day the part be swoln with an oedematous tumor, caused

Hipp. sent. 37. & 38. sect. 1. de fract.
The signs of too strait and loose binding up.

caused by the blood pressed forth of the broken place; but of too strait ligation, if the part be hard swoln; and of too loose, if it be no whit swoln, as that which hath pressed no blood out of the affected part. Now if a hard tumor, caused by too strait binding, trouble the Patient, it must presently be loosed, for fear of more grievous symptoms, and the part must be fomented with warme *Hydraenum*, and another indifferent, yea verily, more loose ligation must be made in stead thereof, as long as the pain and inflammation shall continue; in which time and for which cause, you shall lay nothing upon the part which is any thing burdensome. When the patient begins to recover, for three or four dayes space, especially if you find him of a more compact habit and a strong man, the ligation must be kept firm and not loosed. If on the third day, and so untill the seventh, the spires or windings be found more loose, and the part affected more slender; then we must judge it to be for the better. For hence you may gather, that there is an expression and digestion of the humors, causing the tumor made by force of the ligation. Verily, broken bones fitly bound up, are better set, and more firmly agglutinated, which is the cause, why in the place of the fracture the ligation must be made the straiter; in other places more loosely. If the fractured bone stand forth in any part, it must there be more straitly pressed with boulders and splints. To conclud, the seventh day being past, we must bind the part more straitly then before: for thai then inflammation, pain and the like accidents, are not to be feared. But these things which we have hitherto spoken of the three kinds of Ligatures, cannot take place in each fractured part of the body, as in the chaps, collar-bones, head, nose, ribs. For, seeing such parts are not round and long, a Ligature cannot be wrapped about them, as it may on the arms, thighs, and legs, but only be put on their outsides.

Why we must make more strait ligation on the broken part.

CHAP. VI. *The uses for which Ligatures serve.*

BY that which we have formerly delivered, you may understand that Ligatures are of use to restore those things which are separated and moved forth of their places, and join together those which gape; as in fractures, wounds, contusions, sinewous ulcers, and otherlike affects against nature, in which the solution of continuity stands in need of the help of Bandages, for the reparation thereof. Besides also, by the help of Bandages these things are kept asunder or separated, which otherwise would grow together against nature; as in Burns, wherein the fingers and the hams would mutually grow together; as also the Arm-pits to the Chest, the Chin to the Breast, unless they be hindered by due ligation. Bandages do also conduce to refresh emaciated parts: wherefore if the right leg wast for want of nourishment, the left leg, beginning at the foot, may be conveniently rowled up even to the groin. If the right arm consume, bind the left with a strait Ligature, beginning at the hand, and ending at the arm-pit. For thus a great portion of blood from the bound-up part is sent back into the *vena cava*, from whence it regurgitates into the almost empty vessels of the emaciated part. But I would have the sound part to be so bound, that thereby it become not painfull; for a dolorifick ligation causes a greater attraction of blood and spirits, as also exercise: wherefore I would have it during that time to be at rest, and keep holy-day. Ligatures also conduce to the stopping of bleedings: which you may perceive by this, that when you open a vein with your lancet, the blood is presently stayed, laying on a boulder and making a Ligature. Also Ligatures, are usefull for women presently after their delivery; for their womb being bound about with Ligatures, the blood wherewith their womb was too much moistened, is expelled, the strength of the expulsive faculty being by this means stirred up to the expulsion thereof: and it also hinders the empty womb from being swoln up with wind, which otherwise would presently enter thereinto. This same Ligature is a help to such as are with child, for the more easie carrying of their burden; especially those whose Child lyes so far down-wards, that lying as it were in the den of the hips, it hangs between the thighs, and so hinders the free going of the mother. Therefore the woman with child is not only eased by this binding of her womb with this Ligature, which is commonly termed, the navill Ligature; but also, her child being held up higher in her womb, she hath freer and more liberty to walk. Ligatures are in like sort good for revulsion and derivation: as also for holding of medicins which are laid to a part, as the neck, breast or belly. Lastly, there is a triple use of Ligatures in amputation of members, as arms and legs. The first to draw and hold upwards the skin and muscles lying under it, that the operation being performed, they may, by their falling down again, cover the ends of the cut-off bones; and so by that means help forwards the agglutination and cicatrization; and when it is healed up, cause the lame member to move more freely, and with lesse pain; and also to performe the former actions, this, as it were, cushion or boulder of musculous flesh lying thereunder. The second is, they hinder the bleeding by pressing together the veins and arteries: The third is, they by strait binding intercept the free passage of the animall spirits, and so deprive the part which lyes thereunder of the sense of feeling, by making it, as it were, stupid or num.

The first benefit of Ligatures.

The seventh.

The eighth,

the particu-

lar use of

ligatures in

the amputa-

tion of

members.

CHAP. VII. *Of Boulders or Compresses.*

Boulders have a double use; the first is to fill up the cavities and those parts which are not of an equall thickness to their end. We have examples of cavities in the Arm-pits, Clavicles, Hams and Groins; and of parts which grow small towards their ends, in the arms towards the wrists, in the legs towards the feet, in the thighs towards the knees. Therefore you must fill these parts with boulders & linnen cloths, that so they may be all of one bigness to their ends.

The first use of Boulders

The second use of them.

The third use of them.

The second use of boulders, is to defend and preserve the first two or three Rowlers or Under-binders, the which we said before must be applyed immediately to the fractured part. Boulders, according to this twofold use, differ amongst themselves, for that when they are used in the first mentioned kind, they must be applyed athwart; but when in the latter, long-waves or down-right.

You may also use Boulders, lest the too strait binding of the Ligatures cause pain and trouble to the

new set bones. A three or four times doubled cloth will serve for the thickness of your Boulders, but the length and breadth must be more or less, according to the condition of the parts and disease for which they must be applied.

CHAP. VIII. *Of the use of Splints, Junks, and Cafes.*

Having delivered the uses of Ligatures and Boulders, it remains that we say somewhat of the other things, which serve to hold the bones in their places; as Splints, Junks, Cafes, and such other like. Splints are made and composed of past-board, of thin splinters of wood, of leather, such as shoe-soals are made with; of the rinds of trees, or plates of latin, or lead, and such other like, which have a gentle and yeelding stiffness; yet would I have them made as light as may be, lest they by their weight become troublesome to the affected part. But for their length, breadth, and number, let them be fitted agreeable to the part whereto they must be used. Let also their figure be streight or crooked according to the condition of the member whereto they must be applied. You must have a speciall care, that they run not so far as the swellings out, or eminencies of the bones; as the ancles, knees, elbows, and the like, lest they hurt them by their pressure: also you must have a care, that they be smaller at their ends, and thicker in their middles, whereas they lye upon the broken bone. The use of splints is, to hold fast and firm, that they may stir no way the broken and luxated bones, after they be set and restored to their places. That they performe this use, it is fit there be no thick boulders under them, nor over many rowlers; for so through so thick a space, they would not so straitly presse the part. Junks are made of sticks the bigness of ones finger, wrapped about with rushes, and then with linnen cloth: they are principally used in fractures of the thighs and legs. Cafes are made of plates of latin, or else of some light wood; their use is, to contain the bones in their due figure, when the Patient is to be carried out of one bed or chamber, into another, or else hath need to go to stool: lastly, if we must rest somewhat more strongly upon the broken or luxated members, these Cafes will hinder the bones from stirring or flying out on the right side or left, above or below, we sleeping or waking, being willing or unwilling; and in like sort lest being not as yet well knit, or more loosely bound up for fear of pain, inflammation, or a gangrene, they hang downe, fall, or fly in sunder by reason of the inequalities of the bed. Such Cafes, Junks, and the like, which serve for restoring and fast holding of broken and luxated bones, we may, according to Hippocrates his mind, call them in general *Glossocomia*. All which things, the young Surgeon, which is not as yet exercised in the works of Art, can scarce tell what they are. But in the mean time, whilst that he may come to be exercised therein, or see others perform these operations, I, as plainly as possibly I could, have in words given him their portraiture or shape.

OF FRACTURES.

THE FIFTEENTH. BOOK.

CHAP. I. *What a Fracture is, and what the differences thereof are.*

Fracture, in Galens opinion, is the solution of continuity in a bone, which by the Greeks is called *Catagma*. There are many sorts of hurting or offending the bones: as the drawing them asunder, luxation, or putting them out of joint; their unnaturall growing together, their cutting or dividing asunder; contusion, absesse, putrefaction, rottenesse, laying bare the *periosteum* being violated or lost; and lastly, that whereof we now treat, a Fracture. Again, the varieties of Fractures are almost infinite. For one is complete and perfect, another imperfect; one runs long-wise, another transverse, another oblique; one while it is broken into great pieces, another while into little and small scales, which have either a blunt, or else a sharp end, and prick the adjacent bodies of the muscles, nerves, veins or arteries. It sometimes happens, that the bone is not broken into splinters, that is, long-ways, but together, and at once into two peeces overthwart, which Fracture is called *Raphanodon*, that is, after the manner of a Radish.

A Fracture is made *Caryedon*, or like a nut, when as the bone flies into many small peeces, severed each from other, as when a Nut is broken with a hammer, or mallet upon an Anvile: Which fracture is also termed *Alphitidon*, by reason of the resemblance it hath to meal or flour; and such is often seen in fractures made by bullets, shot out of guns and such fiery Engines. Contrary to these are those fractures which are called *Schidacidon*, as rent into splinters, or after the manner of a boord or peece of timber, that is, right-down, and alongst the bone: and these fractures are either apparent to the eye, or else not apparent, and therefore called *Capillarie*, being so small, as that they cannot be perceived by the eye, unlesse you put ink upon them, and then shave them with your Scrapers. Sometimes the bone is only pressed down with the stroke, sometimes in the contrary it flies up, as if it were vaulted. They call it attrition, when the bone is broken into many small fragments, and as it were scales or chips. The fragments of fractured bones are sometimes smooth and polished, otherwhiles unequall, and as it

Lib. 6. method.

What it is for a bone to be broken *Raphanodon*.

What *Caryedon*, or *Alphitidon*.

What *Schidacidon*.

were sharp and rough with little teeth, or pricks. Some fractures touch only the surface of the bone, fetching off only a scale; other some change not the site of fractured bones, but only cleaves them length-ways, without the plucking away of any fragment; other some penetrate even to their marrow. Furthermore some fractures are simple and alone by themselves; other some are accompanied with a troop of other affects and symptomes; as a wound, hæmorrhagie, inflammation, gangrene, and the like. Hereunto you may also adde the differences drawn from the parts which the Fractures possess; as from the head, ribs, limbs, joints, and other members of the body. Adde also these which are taken from the habit of bodies, aged, young, full of ill humors, well tempered; almost all which have their proper and peculiar indications for curing. Now the causes of Fractures, are the too violent assaults or strokes of all externall things, which may cut, bruise, break, or shake: in this number of causes may also be reckoned fals from high places, and infinite other things, which would be long and tedious to reckon up.

The causes of fractures.

CHAP. II. Of the signs of a Fracture.

WE may know by evident signs that a bone is broken: the first whereof and most certain, is, when by handling the part which we suspect to be broken, we feel peeces of the bone severed asunder, and hear a certain crackling of these peeces under our hands, caused by the attrition of the shattered bones. Another sign is taken from the impotency of the part, which chiefly bewrayes it self, when both the bones, the leg, and brace-bones, the ell and wand are broken. For if only the brace-bone or wand be broken, the Patient may go on his leg, and stir his arm: for the brace-bone serves for the sustaining of the muscles, and not of the body, as the leg bone doth. The third sign is drawn from the figure of the part changed besides nature: for it is there hollow, from whence the bone is flown or gone, but gibbous or bunching out whither it is run. Great pain in the interim torments the Patient by reason of the wronged *periosteum*, and that membrane which involves the marrow and the sympathy of the adjacent parts which are compressed or pricked.

The first sign of a broken bone.

A third.

CHAP. III. Of prognosticks to be made in Fractures.

WE must prognosticate in Fractures whether they are to end in the destruction or welfare of the Patient; or whether their cure shall be long or short, easie, or else difficult and dangerous; and lastly, what accidents & symptomes may happen thereupon. He shall easily attain to the knowledge of all these things, who is not only well seen in the anatomical description of the bones, but also in the temper, composition and complexion of the whole body.

Wherefore in the first place, I think good to admonish the Surgeon of this, that in winter when all is stiffe with cold, by a little fall, or some such sleight occasion, the bones may be quickly and readily broken. For then the bones, being dried, by the dryness of the air encompassing us, become more brittle; which every one of the Vulgar usually observe to happen both in waxen and tallow candles: but when the season is moist, the bones are also more moist, and therefore more flexible and yeelding to the violence of the obvious and offending body. Wherefore also you may gather this to the framing of your Prognosticks, That bones by reason of their naturall dryness are not so easily agglutinated and consolidated as flesh; though in Children, according to *Galen*, by reason of the abundance of their humidity, the lost substance may be repaired, according (as they term it) to the first intention, that is, by restoring of the same kind of substance or matter. But in others, about the Fractures a certain hard substance usually concreats, of that nourishment of the broken bone which abounds, which glues together the fragments thereof, being fitly put together. This substance is then termed a *Callus*, and it is so hardened in time, that the bone thereafter in the broken part is seen to be more firm and hard than it is in any other: therefore that usuall saying in Physick is not without reason; That rest is necessary for the uniting of broken bones. For the *Callus* is easily dissolved, if they be moved before their perfect and solid agglutination. The matter of a *Callus* ought to be indifferent, and laudable in quantity and quality, even as blood which flows for the regeneration of the lost flesh in wounds. It is fit, that there may be sufficient matter for such a *Callus*, that the part have a laudable temper, otherwise there either will be no *Callus*, or certainly it will grow more slowly. Fractures are far more easily repaired in young bodies than in old: for in these there is plenty of the primigenious and radicial moisture, that is laudably holding and glutinous; and in the other there is store of watrish and excrementitious. By this you may easily conjecture, that you cannot certainly set down a time necessary for the generating a *Callus*: for in some it happens later, in some sooner: the cause of which variety is also to be referred to the constitution of the year and region, the temper and diet of the Patient, and manner of Ligation. For, those Patients whose powers are weak, and blood watrish and thin, in these the generation of a *Callus* uses to be more slow: On the contrary, strong powers hasten to agglutinate the bones, if there be plenty of grosse and viscous matter; whereby it comes to passe, that meats of grosser nutriment are to be used, and medicins applied which may help forwards the endeavour of nature, as we shall declare hereafter. When the bones are broken near unto the joints, the motion afterwards uses to be more difficult, especially if the *Callus*, which is substituted, be somewhat thick and bunching forth. But if, together with the violence and force of the Fracture, the joints shall be broken and bruised, the motion will not only be lost, but the life brought in danger, by reason of the greatness of the inflammation, which usually happens in such affects, and the excesse of pain in a tendinous body. These fractures wherein both the bones of the arm or leg are broken, are more difficult to cure, than those which happen but to one of them. For they are handled and kept in their places with more difficulty.

Why bones are more brittle in frostie weather.

Why the solution of continuity in bones is not so easily repaired. *Gal. in arte. par.*

Why bones sooner knit in young bodies.

Meats of grosse and tough nourishment conduce to the generation of a *Callus*.

Fractures at joint dangerous.

difficulty.

ficulty, because that which remains whole, serves the other for a rest or stay to which it may lean. Moreover, there is longer time required to substitute a *Callus* to a great bone, than to a little one. Again these bones which are more rare and spongie, are sooner glued together by the interposition of a *Callus*, than these which are dense and solid. A *Callus* sooner grows in sanguin, than in cholerick bodies. But broken bones cannot be so happily agglutinated, nor restored in any body, but that alwayes some asperity or inequall protuberancy may be seen on that part where the *Callus* is generated. Wherefore the Surgeon ought to make artificiall Ligations, that the *Callus* may not stand out too far, nor sink down too low. That Fracture is least troublesome which is simple; on the contrary, that is more troublesome which is made into splinters: but that is most troublesome and worst of all which is in small and sharp fragments, because there is danger of convulsion by pricking a nerve, or the *periosteum*. Sometimes the fragments of a broken bone keep themselves in their due place: they also oft-times fly forth thereof, so that one of them gets above another; which when it happens, you may perceive an inequality by the depression of the one part and the bunching forth of the other, as also pain by the pricking: besides also the member is made shorter than it was, and than the sound member on the opposite side is, and more swoln by the contraction of the muscles towards their originall. Wherefore when a bone is broken, if you perceive any thing so depressed, presently putting your hand on both sides above and below, stretch forth the bone as forcibly as you can; for otherwise, the muscles and nerves, stretched and contracted, will never of their own accord suffer the bones to be restored to their proper seat and themselves. This extension must be performed in the first dayes, for afterwards there will happen inflammation: which being present, it is dangerous to draw the nerves and tendons too violently; for hence would ensue an impostume, convulsion, gangrene and mortification. Therefore *Hippocrates* forbids you to defer such extension untill the third, or fourth day. Fractures are thought dangerous, whole fragments are great, and fly out, especially in these bones which are filled with marrow on the inside. When broken or dislocated bones cannot be restored to themselves and their naturall place, the part wasts for want of nourishment; both for that the naturall site of the veins, arteries and nerves is perverted, as also because the part it self lies immovable, or scarce movable: whereby it cometh to passe, that the spirits do not freely flow thereto, as neither the nutritive juice cometh thither in sufficient plenty. When the dislocated or broken member is troubled with any great inflammation, it is doubtfull whether or no a convulsion will happen, if we attempt to restore it, or the parts thereof to their seat: therefore it is better, if it may be done, to defer the reducing thereof so long, untill the humor which possesses the part be dissolved, the tumor abated, and the bitterness of pain mitigated.

attempted.

CHAP. IV. The generall cure of broken and dislocated bones.

TO cure a broken and dislocated bone, is to restore it to its former figure and site. For the performance whereof, the Surgeon must propose three things to himself: The first is, to restore the bone to its place: The second is, that he contain or stay it being so restored: The third is, that he hinder the increase of malign symptoms and accidents; or else if they do happen, that then he temper and correct their present malignity. Such accidents are pain, inflammation, a fever, absesse, gangrene and sphacell. For the first intention, you may easily restore a broken or dislocated bone, if presently, as soon as the mischance is got, or else the same day, you endeavour to restore it: for the bitterness of pain or inflammation, which may trouble the Patient, is not as yet very great, neither is the contraction of the muscles upwards as yet very much or stubborn. Therefore first of all, the Patient with his whole body, but especially with the broken or dislocated part, as also the Surgeon, must be in some place which hath good and sufficient light. Then let trusty and skilfull attendants be there, good ligatures, and also, if need so require, good engins. His friends which are present, let them see and hold their peace, neither say, nor do any thing which may hinder the Work of the Surgeon. Then putting one hand above, that is, towards the center of the body, and the other below, as near as he can to the part affected, let him stretch forth the member: for if you lay your hand any distance from the part affected, you will hurt the sound part by too much compression, neither will you much avail your self by stretching it at such a distance. But if you only endeavour below with your hand or ligature, assisting to make extension thereof, it will be dangerous if there be nothing above which may withstand or hold, lest that you draw the whole body to you. This being done, according as I have delivered, it is fit the Surgeon make a right or streight extension of the part affected: for when the bone is either broken or out of joint, there is a contraction of the muscles towards their originall, and consequently of the bones by them, as it is observed by *Galen*. Wherefore it is impossible to restore the bones to their former seat, without the extension of the muscles. But the part being thus extended, the broken bones will sooner and more easily be restored to their former seat. Which being restored, you shall presently with your hand presse it down, if there be any thing that bunches or stands out. And lastly you shall bind it up, by applying bouldsters and splints as shall be fit. But if the bone be dislocated or forth of joint, then presently after the extension thereof, it will be requisite to bend it somewhat about, and so to draw it in. The Surgeon is sometimes forced to use engins for this work, especially if the luxation be inveterate, if the broken or luxated bones be great; and that in strong and rustick bodies, and such as have large joints: for that then there is need of greater strength, than is in the hand of the Surgeon alone. For, by how much the muscles of the Patient are the stronger, by so much will they be contracted more powerfully upwards towards their originals. Yet have a care that you extend them not too violently, lest by rending and breaking asunder the muscles and nerves, you cause the forementioned symptoms, pain, convulsion, a passie and gangrene: all which sooner happen to strong and aged bodies, than to children, eunuches, women, youths, and generally all moist bodies,

When in-
struments or
engins are
necessary.

What bo- dies are sooner hurt by violent extension. Signs of a bone well set.

for that they are less hurt by violent extension and pulling, by reason of their native and much humidity and softness. For thus skins of leather, moistened with any liquor, are easily retched, and drawn out as one pleaseth: but such as are dry and hard, being lesse tractable, will sooner rend and tear, than stretch further out. Therefore the Surgeon shall use a mean in extending and drawing forth of members, as shall be most agreeable to the habits of the bodies. You may know the bone is set, and the setting performed as is fit, if the pain be asswaged; to wit, the fibres of the muscles, and the other parts being restored to their former site, and all compression, which the bones moved out of their places have made, being taken away; if, to your feeling there be nothing bunching out, nor rugged, but the surface of the member remain smooth and equall; and lastly, if the broken or dislocated member compares with its opposite in the composition of the joints, as the knees and ancles answer justly and equally in length and thickness. For which purpose it must not suffice the Surgeon to view it once, but even as often as he shall dresse it. For it may happen, that the bone which is well set, may by some chance, as by the Patients unconsiderate turning himself in his bed, or as it were a convulsive twitching of the member or joints whilst he sleeps, the muscles of their own accord contracting themselves towards their originals, that the member may again fall out; and it will give manifest signs thereof by renewing the pain, by pressing or pricking the adjacent bodies: which pain will not cease, before it be restored to its place: and hereof the Surgeon ought to have diligent care. For if, whilst the *Callus* is in growing, one bone ride over another, the bone it self will afterwards be so much the shorter, and consequently the whole member; so that if this error shall happen in a broken leg, the Patient will halt ever after, to his great grief, and the Surgeons shame. Wherefore the Patient shall take heed, as much as in him lyes, that he stir not the broken member, before that the *Callus* be hardened. Such diligent care needs not be had in dislocations. For these once set, and artificially bound up, do not afterwards so easily fall forth as broken bones. The second scope is, that the bones which shall be restored may be firmly kept in their state and place. That shall be done by Bandages; as ligatures, boulders, and other things, whereof hereafter we shall make particular mention. Hither tend proper and fit medicins, to wit, applying of oil of Roses with the whites of Eggs, and the like repelling things; and then resolving medicins, as the present necessity shall require. It will be convenient, to moisten your rowlers & boulders in oxycrate for this purpose, or else in Rose vinegar, if the Fracture be simple, or with red wine, or the like liquor warm (in *Galens* opinion) if a wound be joined to the fracture; and it will be fit to moisten fractures oftner in Summer: For so the part is strengthened, the defluxion being repelled, whereby the inflammation and pain are hindred. You must desist from humecting and watering the part when the symptoms are past, lest you retard the generating of a *Callus*; for which you must labour by these means which we shall hereafter declare. To this purpose also conduces the rest and lying of the part in its proper figure and site accustomed in health, that so it may the longer remain in the same place unstirred. Besides also, it is expedient then only to dresse the part, when it is needfull, and with those things that are requisite, shunning, as much as may be, inflammation and pain. That figure is thought the best, which is the middle, that is, which contains the muscles in their site, which is without pain; so that the Patient may long endure it without labour or trouble. All these things being performed, the Patient must be asked, whether the member be bound up too strait? If he answer, No, (unlesse peradventure a little upon the fracture or luxation, for there it is fit it should be more straitly bound) then may you know that the binding is moderate. And this same first ligation is to be kept in fractures without loosing for three or four dayes space, unlesse peradventure pain urge you to the contrary. In dislocations the same binding may be kept for seven or eight dayes, unlesse by chance some symptome may happen, which may force us to open it before that time: for the Surgeon must with all his art have a care to prohibit the happening of evill accidents and symptoms, which, how he may bring to passe, shall be declared in the following Chapter.

Causes and signs of a relapse of a set bone.

Ad. sent. 21. sect. 1. de fract.

What the middle figure is and why best.

Fit time for loosing of Ligatures in fractures and dislocations.

CHAP. V. By what means you may perform the third intention in curing fractures and dislocations, which is, the hindring and correction of accidents and symptoms.

Four choice means to hinder accidents.

The causes and differences of itching.

Ad. sent. 4. sect. 1. de fract.

Remedies against the itching.

That we may attain unto this third scope, it is requisite we handle as gently and without pain, as we may, the broken or dislocated member, we drive away the defluxion ready to fall down upon the part by medicins, repelling the humor, and strengthening the part; we, by appointing a good diet, hinder the begetting of excrements in the body, and divert them by purging and phlebotomy. But if these accidents be already present, we must cure them according to the kind and nature of each of them: for they are various. Amongst which is reckoned itching, which in the beginning torments the Patient: this ariseth from a collection and suppression of subacid vapours, arising from the blood, and other humors under the skin. Whence a light biting, which causeth a simple itch, or else a more grievous and acrid one, from whence (in *Galens* opinion) proceeds a painfull itching. Wherefore such matter, as the cause, being evacuated, all itching ceaseth. But this cannot easily and freely be evacuated and breathed out, because the pores of the part are shut up, and as it were oppressed with the burden of the emplasters, boulders, and ligatures, which are put about the part. Hereunto may be added, that the part its self doth not so perfectly perform and enjoy its wonted faculties and actions: by which it commeth to passe, that the heat thereof is more languid than may suffice to discusse the fuliginous matter there collected. Wherefore it will be convenient to loose the ligatures every third day, that as by loosing their eyes, their sanious and fuliginous excrements, shut up under the skin, may freely passe forth, lest in continuance they should fret and ulcerate it; as it happens to most of those who provide not for it by loosing their ligatures. Besides also, the part must be long fomented with hot water alone, or else with a decoction of sage, chamomile, roses,

roses, and melilot made in wine and water : for long fomenting attenuates and evacuates, but shorter sils and mollifies, as it is delivered by *Hippocrates*. Also gentle frictions, performed with your hand, or a warm linnen cloth upwards, to the right side and left, and circularly to every side, are good. But if the skin be already risen into blisters, they must be cut, lest the matter contained thereunder may corrode and ulcerate the skin: then must the skin be anointed with some cooling and drying medicin; as, *ung. album Camphoratum Rhasis, Desiccativum rubrum, unguentum rosatum sine aceto*; adding thereto the powder of a rotten post, or prepared *Tutia*, or the like. Other accidents more grievous than these, do often happen, but we will treat of them hereafter. But if the scales of the bone underneath be quite severed from the whole, then must they be presently taken forth, especially if they prick the muscles: but if the bone be broken into splinters, and so prominent out of the wounded flesh as that it cannot be restored into its seat, it must be cut off with your cutting mallets, or parrats beak, as occasion shall offer its self. In the interim, you must have a care that the part enjoy perspiration, and by change of place and rising, now and then it may be as it were ventilated : also you must see that it be not over-burdened, neither too strait bound, otherwise it will be apt to inflammation. Thus much concerning fractures and dislocations in generall : now we must descend to particulars, beginning with the fracture of the Nose.

Hipp. sent. 46 sect. 3. de fract.

CHAP. VI. Of the Fracture of the Nose.
