Abstract
Objective: Otitis media (OM) is one of the common conditions for doctor visits in the pediatric population. Spinal manipulation therapy (SMT) may be a potential conservative treatment of OM. The purpose of this study is to review the literature for OM in children, outlining the diagnosis of OM, SMT description, and adverse event notation.

Methods: Databases (PubMed, Cochrane Library, Cumulative Index to Nursing and Allied Health, Index to Chiropractic Literature, The Allied and Complementary Medicine, and Alt Health Watch) were queried and hand searches were performed to identify relevant articles. All potential studies were independently screened for inclusion by both authors. The inclusion criteria were as follows: written in the English language, addressed OM, involved human participants 6 years or younger, and addressed SMT. Studies were evaluated for overall quality using standardized checklists performed independently by both authors.

Results: Forty-nine articles were reviewed: 17 commentaries, 15 case reports, 5 case series, 8 reviews, and 4 clinical trials. Magnitude of effect was lower in higher-quality articles. No serious adverse events were found; minor transient adverse effects were noted in 1 case series article and 2 of the clinical trials.

Conclusions: From the studies found in this report, there was limited quality evidence for the use of SMT for children with OM. There are currently no evidence to support or refute using SMT for OM and no evidence to suggest that SMT produces serious adverse effects for children with OM. It is possible that some children with OM may benefit from SMT or SMT combined with other therapies. More rigorous studies are needed to provide evidence and a clearer picture for both practitioner and patients.

Otitis media (OM) is one of the primary conditions for which antibiotics are prescribed in the United States. Failure to distinguish acute otitis media (AOM) from otitis media with effusion (OME) is a possible reason for the use of antibiotics when they are not indicated, and this may contribute to the development of antibiotic-resistant organisms. Acute OM and OME both are upper respiratory tract infections, but children with AOM also have pain and fever. The current recommendation for the treatment of AOM is to use an antibacterial agent (usually amoxicillin). Antimicrobial therapy is not recommended for patients with OME because it typically resolves spontaneously. Because of the concerns of increasing antibiotic-resistant infections and overuse of antibiotics, other methods for conservative care for the common condition of OME are needed. Methods traditionally associated with complementary and alternative medicine (CAM) are usually conservative and do not include pharmaceutical drugs or surgery. Currently, CAM is not considered a potential treatment of either AOM or OME because of limited evidence in the literature.

In addition to musculoskeletal disorders, both the chiropractic and osteopathic professions have claimed that spinal manipulation therapy (SMT) may alleviate disorders involving visceral organs, such as OME. Hypotheses regarding how SMT accomplishes this generally attribute the effects of SMT to biomechanical changes produced in the spine, which subsequently mediate changes in sympathetic or parasympathetic nerve activity.

Certain chiropractic and osteopathic manipulative techniques address the function of cranial structures (including intraoral structures) for treatment of OM. These structures may directly affect the Eustachian tube (ET), which is thought to be the primary structure involved in reoccurrence of OM. The ET has an increase in goblet cells during and up to at least 6 months after OM regardless of the bacterium causing the condition. Otitis media causes an increased secretory capacity of the ET. This increase may contribute to the excessive mucus and deteriorated ET function. These factors could also predispose the patient to the reoccurrence of OM or to a more aggressive middle ear complication.

Another hypothesis, which also indirectly involves the ET, is the impact of cervical manipulation on the lymphatic and muscular systems. Lymphatic flow requires muscular contractions, arterial pulsations, and external compression of body tissues. It is hypothesized that restricted joint movement within the cervical spine may result in muscle hypertonicity restricting lymphatic drainage away from the cranial region. This hypothesis suggests that cervical SMT reduces tension within hypertonic muscles, thus increasing lymphatic drainage.

At present, there has not been a review of the literature summarizing the effects of spinal manipulation therapy (SMT) on OM or the safety of SMT for treating OM. The purpose of this study was to review the literature on the treatment effects of SMT and/or mobilization (including both chiropractic and osteopathic approaches) for all types of OM. This study also evaluates the literature for information relating to the diagnosis of OM, SMT description, and reported adverse events.

**Methods**

**Sources of information**

Relevant studies were identified using the following databases: PubMed, Cochrane Library (CENTRAL), Cumulative Index to Nursing and Allied Health (CINAHL), Index to Chiropractic Literature (ICL), The Allied and Complementary Medicine (AMED), and Alt Health Watch. All databases were searched from inception thru March 2011 (Fig 1). We checked reference lists of relevant studies to identify cited articles not captured by electronic searches.

**Selection criteria**

Because there are few randomized controlled trials (RCTs) and other higher levels of evidence for CAM therapies, such as SMT, we included all levels of evidence. Allowing all levels of evidence provides a comprehensive review of the current state of literature on this subject.

Articles were included if they met the following criteria: (1) written in the English language, (2) addressed OM (acute or chronic), (3) involved human participants 6 years or younger, (4) addressed SMT or osteopathic manipulative therapy to a spinal segment or cranial bone.

**Search terms and delimiting**

Search terms for all databases (except 1) included *otitis media* OR *otitis media with effusion* OR *glue
case reports10; Yang et al developed the checklist for Canadian Medical Association Journal to assess the quality of articles. We used the checklist developed by the Canadian Medical Association Journal to assess the quality of case reports10; Yang et al developed the checklist for case series11; CONSORT (Consolidated Standards of Reporting Trials) was used for the clinical trials12; and QUORUM (Quality of Reporting of Meta-analyses) was used to evaluate the review articles.13 From the results of each checklist, if 25% or less of the criteria were addressed, the article was scored as poor; if 26% to 50% of the criteria were addressed, the article was scored as fair; if 51% to 75% of criteria were addressed, the article was scored as good; and if 76% to 100% of the criteria were addressed, the article was scored as excellent.

Quality assessment

Studies included in the review underwent a quality assessment performed independently by both assessors, with consensus reached between them. If consensus could not be reached, another reviewer would have been invited to resolve consensus. We used the checklist developed by the Canadian Medical Association Journal to assess the quality of case reports10; Yang et al developed the checklist for case series11; CONSORT (Consolidated Standards of Reporting Trials) was used for the clinical trials12; and QUORUM (Quality of Reporting of Meta-analyses) was used to evaluate the review articles.13 From the results of each checklist, if 25% or less of the criteria were addressed, the article was scored as poor; if 26% to 50% of the criteria were addressed, the article was scored as fair; if 51% to 75% of criteria were addressed, the article was scored as good; and if 76% to 100% of the criteria were addressed, the article was scored as excellent.

Results

We identified 1489 articles and found 62 to be potentially eligible (Fig 1). Of the 62 reports— 17 were surveys/editorials/commentaries, 15 were case reports, 5 were case series, 8 were reviews, and 4 were clinical trials. There were a total of 13 reports that could not be included after reviewing the entire article: 7 had patients older than 6 years, 2 did not include OM, 2 did not have SMT as part of the interventions, and 2 had multiple reasons. Thus, 49 articles were included in the final evaluation. Tables 1 to 5 summarize the body of evidence for each reporting style.

There were 15 case reports (Table 1) included in this study. Each resulted in a decrease of OM symptoms or improved hearing. Seventeen of the articles involved chiropractic SMT, 1 used osteopathic care, and 1 described integrative care including chiropractic. The type of OM was described as definitely chronic in 9 of the articles and definitely acute in 3. Overall, the quality of the articles was fair; and there was no mention of adverse events.

Case series, described in Table 2, also demonstrated decreased recurrent symptoms or number of reoccurring episodes of OM. There were 4 articles that used chiropractic care and 1 that used osteopathic manipulative care. The exact definition of OM was different for each article. One article reported that there were no complications following care. In general, the quality of these articles was rated as good.

There were a total of 4 articles describing 3 different clinical trials (Table 3). One of the trials recruited acute OM patients (2 articles), 1 had chronic OM with effusion, and the final article recruited patients with recurrent OM. There were a total of 167 patients enrolled into these clinical trials, and most reported a decrease in symptoms. Two of the 3 clinical trials used osteopathic manipulation. Overall, the quality of the articles was excellent, with 2 of the articles reporting minor, transient adverse events.

The review articles’ quality ranged from excellent (2) to good (2) to fair (3) (Table 4). All of the review articles were published in peer-reviewed journals during the past 10 years. The overarching summary statements of these articles varied greatly. One stated that SMT may decrease frequency of OM, another stated that the results are inconclusive, and another found no credible solid evidence.

The final table (Table 5) reports the list of commentaries (10), letters to editors (3), cross-sectional surveys (3), and protocols (1) on the subject of OM and

SMT. Conclusions varied with the type of writing, but the majority supported the use of SMT for OM.

### Discussion

Most of the literature from this narrative review comes from case reports, case series, surveys, and commentaries rather than RCTs of high quality. There appears to be a potential benefit from SMT in pediatric patients with OM; but more rigor needs to occur with quality of writing, reporting of adverse events, and reporting diagnosis and differential diagnosis.

For this review, the higher the literature was on the evidence pyramid, the better its quality. There are many books, commentaries, and checklists to help authors ensure that their manuscript adds value to the literature. However, writing is a difficult and time-consuming task. The quality of OM manuscripts could be improved tremendously if clarity regarding the mechanisms of SMT, how the diagnosis was reached, and reports of adverse events were included.

Few if any adverse events have been reported with SMT for the pediatric population. Causation and incident rates have not been studied; so careful reporting of events, even minor, needs to be included when writing a manuscript. All checklists and other tools for writing manuscripts should include this item to ensure that authors are aware of its importance. When reported amongst the articles in this review, adverse effects were minor and transient.

Pichichero has been writing about the importance of diagnostic accuracy of OM and its difficulties for several years. Ferrance and Miller describe the 3 separate and distinct entities of OM and how they are typically differentiated by otoscopy with insufflation to check for appropriate movement of the tympanic membrane. This procedure requires rigorous training, and its difficulty is well known.

Clinical trials are most often designed to be explanatory or efficacy trials to determine whether an intervention has an effect under ideal circumstances. Case reports classically occur in “real-world” clinical settings. The next step involves conducting effectiveness or pragmatic trials, which are intended to measure the degree of beneficial effect in a more “real-world” setting. A pragmatic clinical trial that explores the benefits of SMT in children with OM enhances its generalizability for clinical practitioners. If these trials provide strong evidence for an intervention, establishing protocols for efficacy trials can be substantiated with the prior pragmatic trials’ intervention and clinical settings.
Limitations

This literature review has the inherent limitation of misleading conclusions. The use of more reviewers or a formalized analysis could have reduced potential bias and misleading conclusions. A second limitation of this review is the use of checklists. Checklists remove considerable subjectivity, but reviewer interpretation and limited criterion can lead to misjudgment or improper scoring of an article. Another limitation was that this was not a rigorous systematic review. We attempted to retrieve all relevant articles; but without using all the methods of a systematic review, we may have inadvertently missed some articles. The studies included in this literature review may not have included or accurately reported adverse events; thus, it is possible that adverse events were underreported.

Conclusions

From the 49 studies (17 surveys/editorials/commentaries, 15 case reports, 5 case series, 8 reviews, and 4 clinical trials) found in this report, there was limited quality evidence for the use of SMT for children with OM. There are currently no evidence to support or refute using SMT for OM and no evidence to suggest that SMT produces serious adverse effects for children with OM. More rigorous studies are needed to provide evidence and a clearer picture for both practitioner and patients.

Acknowledgment

The authors thank Maria A Hondras, DC, MPH; and Cynthia R Long, PhD; and Angela Ballew, DC, MS, for assistance with this manuscript. They also thank Dana Lawrence, Paige Morgenthal, and John Stites for their editorial assistance.
